In another department is an answer to an inquiry relative to methods for learning Spanish. It is gratifying to note that the Spanish edition of The Journal has been instrumental in awakening greater interest in the Spanish language. Both for business and cultural reasons the Spanish tongue and literature should be better known in the United States. Those who take the pains to learn Spanish will find themselves amply repaid by the wealth of a literature which only now is beginning to be appreciated fully in this country. Unfortunately, many English translations of Spanish works which are available are not of the best. If the new era of friendship among nations is to develop—especially among the nations of the western hemisphere—the different peoples must become better acquainted. One way to accomplish this is by learning the foreign languages. We seem to be today no nearer than in the days of the Tower of Babel to that time when a universal language shall rise from the ruins of Latin, Volapük, Esperanto and Ido. It may not be amiss to say that those interested in Spanish will find an unusually easy method of improving their knowledge by comparing the translations in the Spanish edition of The Journal with the English original. In this way they may enrich their vocabulary and learn some of the finer distinctions in the grammatical construction of the two languages. One of the greatest of the Spanish monarchs is credited with saying that a man is worth as many men as languages he knows.

AN EXPLANATION OF DIGESTIVE LEUKOCYTOSIS

Digestive leukocytosis is an expression that has been employed for many years to indicate the fact that white blood corpuscles are found in the blood in unusually large numbers during the period of absorption of digestion products, particularly after a meal rich in proteins. This phenomenon has been appealed to in support of a now discarded hypothesis that the leukocytes play an important part in the transport of digestion products from the intestine to remote parts of the organism. The suggestion was made that the leukocytes are mobilized in large numbers in the intestinal wall during absorption to assist in the removal of the alimentary contributions into the circulation. Without presenting the arguments that led to the abandonment of the assumptions thus made, we may point out that the observed facts—the existence of a postprandial leukocytosis—remain valid. The maximum count occurs a few hours after the meal. According to investigations of Goodall, Gulland and Paton,[1] the blood change is chiefly due to a very constant increase in the number of lymphocytes, contributed to much less regularly by a relative increase in the polymorphonuclear cells. They further demonstrated that the source of the leukocytosis is entirely, or almost entirely, the bone marrow, in which they found an increased rate of production of white corpuscles during digestion. These long known facts in relation to "digestive leukocytosis" now seem capable of further elucidation. At the physiologic laboratory of McGill University, Montreal, Downs and Eddy[2] have shown that subcutaneous injection of secretin, the hormone that excites the flow of pancreatic juice, brings about a considerable increase in the number of red and white corpuscles in the blood stream by directly stimulating the production of new cells. If, as is now generally believed, secretin enters the circulation and is carried in the blood during digestion, there is no apparent reason why it should not thus normally be at least as potent a stimulus to blood cell formation as when experimentally introduced into the circulation. The similarity between the differential leukocyte counts during digestion and after the administration of secretin is, according to Downs and Eddy, additional evidence of secretin's being the cause of the increase in the number of corpuscles during digestion.

---

Medical Mobilization and the War

Personnel of the Medical Corps

For the week ending March 28, the Medical Corps contained 19,655 officers, a decrease from the previous week of 588. The Medical Reserve Corps contained 1,319 officers. The total number of medical officers discharged since the beginning of the war is 13,705.

Casualties Among Medical Officers of the A. E. F. in France

From July 1, 1917, to March 13, 1919, there were 442 casualties among medical officers of the American Expeditionary Forces in France, divided as follows: died of wounds, 22; died of accident, 9; died of diseases, 101; killed in action, 46; lost at sea, 4; missing in action, 7; prisoners not wounded, 28; suicide, 3; wounded in action, degree undetermined, 47; wounded in action, severely, 93; wounded in action, slightly, 72.

Awards of Military Cross

Under authority delegated by King George the Fifth the field marshal commanding in chief has awarded the military cross for gallantry and devotion to duty in action to Sydney S. Schochet, Lieut., M. C., U. S. Army, Chicago, attached to the Highland Light Infantry.——Dr. Vincent M. Diodati, Philadelphia, who enlisted in the army the day the United States declared war and sailed with the first detachment of American medical officers sent over to be attached to the British forces, has been notified he will receive the coveted military cross from the hands of King George of England.

New Base Hospital Publications

Many of the base hospitals are now issuing special publications. The first number of the *Mess-Kit,* "written and published by the enlisted men of the U. S. Army Base Hospital, Camp Merritt, N. J., for the amusement and profit of patients from overseas, soldiers, sailors, marines and for all men and women in the service or out of it who have helped to 'make the world safe for democracy,'" has just been received. It is a monthly publication, well illustrated, instructive and interesting.——*Asyouwere* is the title of a publication issued weekly by U. S. Army General Hospital No. 24 at Pittsbugh, Lieut.-Col. E. D. Kramers, commanding officer. It contains much stimulating material, personal items, original cartoons, etc.

Medical Manuscripts Based on Military Facts to Be Submitted to Surgeon-General Before Publication

The Surgeon-General announces that the order requiring medical officers to submit to the Surgeon-General's Office for approval medical manuscripts based on military or official records or on military experience during the war is still in force as far as medical officers on active duty are concerned. Officers retired from active duty are requested to do likewise as a courtesy to the Surgeon-General and in aid of assembling material for the medical history of the war. Manuscripts are to be accompanied by a carbon copy. If approved, the original copy will be forwarded to the journal designated for publication, and the carbon will be filed in the records of the Medical History of the War.

Neosalvarsan Smuggled

According to *Oil Paint and Drug Reporter,* 1,900 ampules of neosalvarsan, said to have been smuggled into this country from Germany by an officer of the Medical Division of the United States Army, were seized by customs officials at Kansas City last week. The Army officer, whose name is withheld by the officials, is said to be in the East, and his arrest is expected momentarily. The value of the goods seized is estimated by the customs officials at $18,000. This is believed to be only a part of a larger amount smuggled into the United States. The duty, under normal conditions, would be about $6,000 on the quantity seized.

Federal officials say that the officer who brought the drug into this country is not only guilty of smuggling, but has violated the provision which prohibits the importation of goods obtained through "trading with the enemy," and has also violated the Pure Food and Drugs act when he failed to submit it for inspection under the provision of that act on his arrival here.

Regulations Governing Conversion of War Risk Insurance

The regulations governing the conversion to standard forms of life insurance policies of all war-time term insurance taken out by soldiers and sailors since the entrance of the United States into the war have been approved by Secretary Glass. After conversion this insurance will be known as government life insurance.

The forms of policies which may be had in exchange for the war-time term insurance are: ordinary life, twenty-payment life, thirty-payment life, twenty-year endowment, thirty-year endowment and endowment payable at the age of 62. The premium rates for these converted policies are lower than those charged by private insurance companies. The policies contain exceedingly liberal privileges, providing for cash and loan values, paid-up and extended insurance, and further providing that the insured will be paid for life a monthly income in the event that he becomes totally and permanently disabled. All of these policies are incontestable from date of issue and are free from restrictions as to residence, travel or occupation. The holders of the policies will be eligible to share in and receive dividends from gains and savings and the proceeds of the policies are exempt from all taxation. Premiums on the new forms of government insurance are payable monthly and may be paid at any time during the month. They may also be paid annually, semiannually or quarterly.

Awards of Distinguished-Service Cross

By direction of the President, under the provisions of the act of Congress approved July 9, 1918, the Distinguished-Service Cross was awarded by the commanding general, American Expeditionary Forces, for the extraordinary heroism in action in Europe, to the following-named officers and enlisted men of the American Expeditionary Forces:

LOUIS DIENER, Capt. Medical Corps, Sanitary Detachment, 112th Machine Gun Battalion, Baltimore. For extraordinary heroism in action in the Ravine de la Veux Michieux, France, Oct. 26-27, 1918. On being notified that an enemy shell had struck a dugout occupied by the brigade radio detachment, he ran to the aid of the buried men and worked tirelessly to rescue them. Despite the fact that numerous gas and high explosive shells were falling in the vicinity, he continued his efforts until he was certain that the three men remaining in the ruined dugout were dead.

GEORGE E. McGINNIS, Capt. Ambulance Company 110, 103d Sanitary Train, Philadelphia. For extraordinary heroism in action at Fismette, France, Aug. 9-10, 1918. During the night of August 9, Captain McGinnis, with complete disregard of his personal safety, made a reconnaissance under fire and located a line of evacuation for ambulances from Fismette, and on the morning of August 10, under shell fire, he personally repaired the bridge between Fismes and Fismette, thereby making possible the evacuation of twenty-eight wounded men.

WILLIAM H. J. O'BRIEN, Lieut., M. C., U. S. Army, New York, on duty with the 76th U. S. Field Artillery, A. E. F. For extraordinary heroism in action near La Trinité Ferme, France, July 14-15, 1918. During the entire night of July 14-15 and throughout the following day, Lieutenant O'Brien was continually exposed to high explosive and gas shells in caring for the wounded, even after he had been painfully wounded by a fragment of a shell.

HENRY E. BUNCH, Capt., M. C., U. S. Army, 168th Infantry, Kennecott, Alaska. For extraordinary heroism in action near the Bois de Chatillon, France, Oct. 13-16, 1918. During the advance of his regiment in the Verdun sector he established aid stations at points as far advanced as possible and supervised them throughout the combat, working continuously, tirelessly, and fearlessly without food or rest. October 14, this officer went out in advance of the front line to reconnoiter a site for an aid station, and ambulance route. Seeing a wounded officer lying about 300 meters from the enemy's line, he went to his rescue and carried him through terrific machine gun and rifle fire to a shell hole, where he administered aid, in entire disregard of his own safety.

URBANE F. BASS, Lieut., M. C., U. S. Army, 372d Infantry, Fredericksburg, Va. For extraordinary heroism in action near Monthois, France, Oct. 1-6, 1918. During the attack on Monthois he administered first aid in the open under prolonged and intense shell fire until he was severely wounded and carried from the field.

WILLIAM H. J. O'BRIEN, Lieut. M. C., U. S. Army, 76th Field Artillery, New York City. For extraordinary heroism in action near La Trinité Ferme, France, July 14-15, 1918. During the entire night of July 14-15, and throughout the following day, Lieut. O'Brien was continually exposed to high explosives and gas shells in caring for the wounded, even after he had been painfully wounded by the fragment of a shell.

-**RALPH E. SWARTS**, Lieut., M. C., U. S. Army, 23d Infantry. For extraordinary heroism in action near St. Etienne á Arnes, France, Oct. 3-9, 1918. During the offensive operations of Oct. 3-9 Lieutenant Swarts worked unceasingly in the most advanced stations in the divisional sector dressing the wounded in the open under terrific machine gun and shell fire. He took cover only when all wounded had been dressed and evacuated.

Weekly Bulletin, A. E. F.

(*March 3, 1919*)

[NOTE.—We quote the following verbatim as it is evidently descriptive of cases of epidemic lethargic encephalitis occurring among the troops. It is evidence of the difficulty of men working in the field without access to current medical literature to keep abreast of medical knowledge.—ED.]

HAVE YOU SEEN ANY OF THESE CASES?

(CONTRIBUTION BY CHIEF OF MEDICAL SERVICE, BASE HOSPITAL NO. 214)

"A number of cases with unusual neurological findings have been observed at the hospital center at Savenay. They seem sufficiently important to make it desirable to ascertain whether similar cases have been met with in other hospitals in the A. E. F.

"These cases have followed rather mild infections (mumps, influenza, accessory nasal sinus infection, and possibly abortive cerebrospinal meningitis). Many of the clinical features resemble Parkinson's disease, namely masklike facies, slow, shuffling gait, with or without tremor of head and hands, moderate exaggeration of the deep deflexes, lack of timbre of voice tones, definite depression, moderate anxiety and apprehension. The clinical picture is somewhat similar to that seen after recovery from severe carbon-monoxide poisoning. It would seem most probable that these conditions are the result of degeneration of the lenticular nucleus, possibly of a toxic origin.

"The purpose of this note is to bring this condition to the attention of medical officers because it is thought that there are undoubtedly other such cases scattered through the various hospitals in the A. E. F. and it is very desirable to obtain accurate clinical observations in order that the disorder may be carefully studied and identified."

The senior consultant in neuropsychiatry would be glad to have case histories suggesting this order sent to him.

The clinical description may represent only accidental association of symptoms, but it is only by the analysis of such unexplained phenomena that syndromes are gradually crystallized into permanent clinical entities.

MONTHLY REVIEW

The month of February showed a reduction in the total cases reported of 199 as compared with the total for January. This reduction occurred in diphtheria, measles, meningitis, paratyphoid and typhoid fevers and smallpox. The greatest decrease was in typhoid fever, which showed a reduction from 333 cases in January to 171 in February. There were slight increases in dysentery and scarlet fever.

WEEKLY REVIEW

There has been a total reduction of forty-nine cases in the week. Typhoid and paratyphoid show sharp reduction to the lowest figure reported since November. Fewer new foci and organizations with new cases have been reported. There have been reductions in scarlet fever, in measles and in diphtheria. Meningitis has increased by seven cases. The incidence rate for new cases of venereal disease has risen, the rate per thousand per annum being 34.30 as compared with 34.29 last wek. Typhus fever is reported as having appeared among our troops in a small detachment at Cattaro, Dalmatia.

ANNUAL VENEREAL DISEASE RATE, PER 1,000 OF STRENGTH, FOR THE WEEK ENDING MARCH 3, 1919

Section	Rate	Section	Rate	Section	Rate
1	85	6	106	Paris	180
2	32	7	86	1st Army	12
3	10	Adv.	41	2d Army	18
4	49	Tours	104	3d Army	11
5	67	Int.	48	Divisions in S. O. S.	34
Annual rate per 1,000 for whole A. E. F.					34.30

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

Passed Asst. Surg. R. H. HETERICK, relieved at the marine hospital, Savannah, Ga.; proceed to Rotterdam, Holland, for duty in the office of the American Consul General.

Passed Asst. Surg. J. A. WATKINS, report to the director of the Hygienic Laboratory for duty in the transfer of hospital and laboratory supplies and other equipment.

Passed Asst. Su[illegible], relieved from duty with the division of venereal [illegible] or duty in the office of the Chief Medical Advisor [illegible] War Risk Insurance.

Asst. Surg. S. L. CHRISTIAN, relieved at Norfolk, Va., proceed to Savannah, Ga., and take charge of the marine hospital.

[illegible] WILLIAM S. BEAN, Jr., proceed to Lakehurst, N. J., [illegible] to ascertain their suitability for a hospital of this [illegible]

[illegible] T. B. H. ANDERSON, report for temporary duty in the [illegible] the Chief Medical Advisor of the Bureau of War Risk [illegible]

Surg. J. C. TRAVERS (Reserve), relieved at the Baltimore quarantine station; proceed to the marine hospital, Boston, Mass., pending assignment to the Coast Guard Cutter *Tallapoosa*.

Asst. Surg. LEE H. CURRAN (Reserve), proceed to the marine hospital, San Francisco, Calif., pending assignment to Coast Guard Cutter *Unalga*.

Acting Asst. Surg. J. B. ELLIOTT, relieved at Little Rock, Ark., proceed to Camp Sevier, Greenville, S. C., for duty.

Acting Asst. Surg. M. P. McNEIL, relieved at Lonoke, Ark., proceed to Camp Sevier, Greenville, S. C., for duty.

Acting Asst. Surg. M. H. WATTERS, relieved at the Bureau. Proceed to Camp Sevier, Greenville, S. C., for duty.

Acting Asst. Surg. WILLIAM A. WILSON, proceed to Washington, D. C., for conference relative to the work of venereal disease control [illegible] ew York.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

ILLINOIS

Chicago

Personal.—Dr. Martin B. Jelliffe, formerly of Mansfield, Ohio, who was recently discharged from the Medical Corps, U. S. Army, has located in Springfield.——Dr. Edmund J. Doering, Chicago, has been commissioned Lieut.-Col., M. C., U. S. Army.

INDIANA

Venereal Disease Clinic.—Dr. William F. King, Acting Asst. Surg., U. S. P. H. S., Indianapolis, announces the opening of the fifth free venereal disease clinic of the state at East Chicago. The other clinics are at Evansville, Anderson, Muncie and Indianapolis.

Society Organized.—Physicians of Ripley County met in Osgood, recently, and organized the Ripley County Medical Society, and elected Dr. Lafayette T. Cox, Napoleon, president; Dr. John N. Hess, New Marion, vice president, and Dr. Edward D. Freeman, Osgood, secretary-treasurer.

Personal.—Dr. Frank C. Hershey, Carmel, who recently was operated on for gallstones in Indianapolis, is reported to be improving.——A, Parker Hitchens, Philadelphia, formerly director of the H. K. Mulford biologic laboratory, has been appointed associate director of the biologic department of the Lilly Laboratory.

State Board Divisions.—February 24, four new divisions were created in the state board of health with proper appropriations: division of rural hygiene, $25,000; division of venereal diseases, $29,000; division of tuberculosis, $10,000, and for the distribution of 30,000 copies annually of the Indiana Mothers Baby book, $5,000.

IOWA

Personal.—Walter E. Foley, Lieut., M. C., U. S. Army, Davenport, who entered the United States service in June, 1918, and is on duty with the American Expeditionary Forces in France, has been appointed chief of the surgical service of Base Hospital No. 53.

Commencement.—The midwinter commencement exercises of the State University of Iowa College of Medicine, Iowa City, were held, March 27. The chief speaker was Dr. Dean D. Lewis of the University of Chicago, who spoke on "Medical Experiences of the Last Offensive."

MARYLAND

Army Nurses to Be Treated Here.—The Surgeon-General of the United States Army has selected the Sheppard and Enoch Pratt Hospital at Towson as one in which army nurses who have been mentally affected are to be brought for treatment. It is thought that with the facilities offered at the hospital for indoor and outdoor treatment they will rapidly recover their normal condition. About fifteen will be admitted immediately, and the hospital is making preparations to take in as many as possible.

Personal.—Capt. Sydney M. Cone is confined to his home in Baltimore with an attack of pleurisy. He was taken ill while on duty at Fort McHenry, U. S. Army General Hospital No. 2.——Col. Thomas R. Boggs, Baltimore, formerly of the Johns Hopkins Unit, has arrived from overseas on the transport *George Washington*.——Amos F. Hutchins, Capt., M. C., U. S. Army, Baltimore, an associate at the James Buchanan Brady Institute, Johns Hopkins Hospital, who served for a time with the British forces and was later transferred to the Johns Hopkins Base Hospital in France, addressed the South Baltimore Medical Association at a recent meeting on "Experiences in the Front Line Trenches and in No Man's Land."

MASSACHUSETTS

Personal.—Dr. Hugh Cabot, Boston, has been appointed director of clinics in the subdivision of venereal diseases of the state department of health. His efforts will be toward the standardization of work in the sixteen state approved venereal clinics and toward familiarizing the physicians of the state with the opportunities for expert treatment and advice to be found in them.

Cutter Lectures.—The Cutter lectures on "Preventive Medicine and Surgery" were delivered at the Harvard Medical School, March 17, by Harry E. Mock, Lieut.-Col., M. C., U. S. Army, Chicago, Division of Reconstruction of Disabled Soldiers, War Department, on "Industrial Medicine Considered from the Economic Viewpoint," followed by "Reclaiming of Disabled," illustrated by moving pictures; and by Dr. Alice Hamilton, special investigator, U. S. Department of Labor, Chicago, on "Industrial Poisoning in the United States," considered under the following heads: "Lead," April 2; "Other Organic Poisonings," April 3; "Poisons of the Aromatic Series, and of the Fatty Series," April 4.

MICHIGAN

Diphtheria Epidemic.—An epidemic of diphtheria is reported from the village of Pottersville. Schools have been closed, and several families have been placed under quarantine.

Campaign Against Venereal Disease.—The process of internment instituted as a war emergency measure, Nov. 12, 1917, by the state board of health for the care and treatment of cases of venereal disease has been exceedingly successful and a complete card catalogue system has been prepared which contains the fullest information possible, although the rights of the individual are safeguarded. About 8,000 women have been tabulated thus far. The legislature is to be asked to pass more stringent laws to enforce the reporting of such cases, and to appropriate $300,000 to carry on this work for the next two years. There are eight hospitals in the state with 321 beds for the care of venereal patients and 1,300 patients have already been sent to hospitals. They are being given the choice of internment or of being placarded and quarantined, but it is possible for patients afflicted with venereal disease, to receive treatment at public health clinics without publicity.

MINNESOTA

Clinical Association Organized.—The medical staff of the Minneapolis City Hospital has organized a clinical association with an initial membership of about fifty. Dr. Archa E. Wilcox is president; Dr. Harry A. Britton, vice president, and Dr. John E. Hynes, secretary-treasurer of the organization.

MISSOURI

Neurologic Clinic.—A scientific session of the Buchanan County Medical Society was held at State Hospital No. 2, St. Joseph, March 19. The superintendent of the hospital, Dr. Porter E. Williams, entertained the society at dinner, and this was followed by a neurologic clinic arranged by the hospital staff.

Personal.—Dr. Hanau W. Loeb, dean of the St. Louis University School of Medicine, is one of the administrators of the estate of the late John T. Miliken, millionaire chemist of St. Louis, and has found the duties imposed on him so numerous that the school has appointed Dr. Don R. Joseph, professor of physiology, as assistant dean.——Dr. G. Canby Robinson, St. Louis, associate professor of medicine and acting dean of Washington University Medical School, has been elected dean of the school.——Buchanan County Medical Society has indorsed the administration of Dr. Porter E. Williams, superintendent of State Hospital No. 2 at St. Joseph, and congratulated Governor Gardner on the appointment of Dr. Williams. The society also indorsed the work of Dr. Hasbrouck DeLamater, city health officer, and Dr. Daniel Morton, St. Joseph, member of the social welfare board, and petitioned the mayor of St. Joseph to reappoint them.

Clinic Organization.—The St. Louis Medical Society has appointed a committee to organize the clinics in St. Louis with the view of correlating the clinical material of the city for the purpose of establishing a method of announcing the work to be done in each clinic from day to day in order that the local profession and visiting physicians may have better opportunity to observe the work done by St. Louis physicians. It is proposed to form an organization that will furnish a central bureau of information concerning the schedule of cases so that a physician who desires to see work in some particular branch of medicine can be directed to a clinic without delay. The following members have been appointed chairmen of committees in each of the branches mentioned: Charles H. Neilson, medicine; John R. Caulk, genito-urinary; Jules M. Brady, pediatrics; Harvey S. McKay, surgery; William W. Graves, neurology; William E. Sauer, nose and throat; Frederick J. Taussig, gynecology and obstetrics; Edward H. Higbee, Jr., eye, and J. Archer O'Reilly, orthopedics.

Progress of Medical Legislation.—House Bill 859, introduced by Dr. Asier J. Speer of Bollinger County, amends the medical practice act by striking out the word "reputable" and substituting therefor the words "legally chartered." By this substitution the state board of health would be compelled to examine the applicants of any medical college that held a legal charter, irrespective of the character, quality and quantity of equipment the college possessed or of the reputability of its staff and methods of graduating of students. The bill further amends the present act by omitting certain words in the premedical educational qualifications which would further lower the standards of medical education in Missouri. House Bill 360 (the chiropractic bill) is in the committee on criminal jurisprudence; it has been reported that the committee contemplates amending the bill so as to require applicants in chiropractic to obtain a license from either the state board of osteopathy or the state board of health; in the senate (S. B. 232) this bill has been reported unfavorably. House Bill 905 (limiting fees physicians may charge to $1.50 a call, $1 in the office and $10 for any obstetric case) is in the committee on public health; in the senate no companion bill has been introduced. House Bill 909 (writing prescriptions in English) is in the committee on publi[illegible]lth; in the [illegible] (S. B. 662) this measure has bee[illegible]d unfavo[illegible]enate Bill 663 (placing on surge[illegible]rden of [illegible]t due care has been exercised in [illegible] when [illegible]n is sued for malpractice) is in [illegible] on [illegible]ary institutions. House Bill 1[illegible] has been passed with the co[illegible] fro[illegible] ph[illegible] by the injured [illegible] usi[illegible] e senate the bill [illegible] ee.

[illegible] alth officers [illegible] uate course [illegible] eing given [illegible] artment of

Drug Bill Defeated.—The bill sponsored by Governor Smith which provided that the recently created state commission of narcotic drug control be abolished and its functions transferred to the state department of health was defeated in the assembly, March 27, by a motion which refused to release it from committee. A similar action was taken by the senate a week before.

Committee to Investigate Alcoholic Content of Medicines.—The state excise committee, in reporting the bill which gives to the state excise commission authority to enforce the prohibition amendment to the United States constitution, has amended the bill to provide for a committee of three physicians and two druggists to pass on the 250 medicines now in the market for the purpose of determining whether they are beneficial, harmless or intoxicating.

Personal.—Dr. Hermann M. Biggs, state commissioner of health, has been granted six weeks' leave of absence and is new en route to France, where he will aid in the establishment of an international Red Cross society.——Dr. Francis J. Cahill, health officer of Hoosick Falls, has been commended in a letter to the Surgeon-General of the Army by Brig.-Gen. Edward B. Billingham, for services rendered to sick soldiers while in the German prison camp at Graudenz, West Prussia.

County Tuberculosis Survey.—As a result of the tuberculosis survey recently held in Clinton County, the board of supervisors has appropriated $1,200 and the necessary traveling expenses for a county tuberculosis nurse, for one year. ——Immediately following the survey, four persons made application for care at Ray Brook or at a county tuberculosis hospital.——As a result of a county tuberculosis survey, a neglected case of empyema was found and sent to a hospital, where immediate operation undoubtedly saved the child's life.

New York City

Dinner to Colonel Lambert.—A complimentary dinner to be tended to Col. Alexander Lambert, American Red Cross, at the Hotel Commodore, April 12, at 7 o'clock, in recognition of his work for the medical profession in the state and nation and overseas.

Harvey Society Lecture.—The seventh lecture of the Harvey Society series will be given at the New York Academy of Medicine, April 12, by Dr. Stewart Paton, Princeton, N. J., formerly Major, M. C., U. S. Army, on "Human Behavior in War and Peace."

Personal.—Dr. Simon Baruch is seriously ill with heart disease at his home.——David Edward Hoag, Capt., M. C., U. S. Army, has received his discharge from the service and has been appointed attending neurologist at the New York City Hospital, and also visiting neurologist at the West Side Hospital and chief of the clinic on nervous and mental diseases at the West Side Dispensary and Hospital.

Hospitals Ask Voice in Legislation.—The Hospital Conference of the City of New York, representing forty institutions in this city which maintain nurses' training schools, have appealed to the commissioner of education for a hearing on the proposed legislation affecting hospitals. This action was taken because several bills have been introduced into the legislature during the past few years which, if passed, would revolutionize the training of nurses in hospitals. At present there is an amendment to the nursing bill at Albany which provided for the training of short term nurses or attendants. The hospitals fear that there is a demand for this class of attendants; but since the hospitals will be given the training of these students, they feel that they should be consulted in the matter.

OHIO

Personal.—John D. O'Brien, Major, M. C., U. S. Army, Canton, on duty with the American Expeditionary Forces, was promoted to lieutenant-colonel, M. C., February 15.——Dr. William S. Fox has been appointed a medical inspector in Cleveland public schools.

Educational Committee Appointed.—At a meeting of the council of the Ohio State Medical Association, held in Columbus, March 10, Drs. Charles Edwin Briggs, Cleveland; William D. Porter, Cincinnati, and Harry E. Hunt, Newark, were appointed an educational committee to continue the campaign against venereal diseases. Lectures and clinics for physicians are to be held throughout the state, at which the latest and most improved methods of combating venereal disease will be explained and discussed.

Hughes Bill Passes House.—The Hughes bill, which establishes each city of over 25,000 population as a separate health district, and each county area outside of such city as a separate district, has passed the lower house by a vote of 81 to 14, and is now before the senate for consideration. Under this bill the maximum number of districts possible will be 102, as compared with 2,150 at present. The bill authorizes combinations of districts to reduce the overhead expense. Each district is to have a full-time health officer and at least one public health nurse, with such additional health employees as are necessary to provide an adequate health administration.

OREGON

Sanitary Engineer to Be Employed.—At the instance of Representative Childs, the Ways and Means Committee has rescinded its action reducing the appropriation for the state board of health, and has added $10,000 to the appropriation for the employment of a sanitary engineer.

State Mental Hygiene Committee.—The following named physicians have been appointed a state mental hygiene committee, which will support the bill now pending in the legislature providing for the survey of state institutions for the insane and feebleminded: Dr. Jonah B. Wise, temporary chairman; Dr. Samuel Kohs of Reed College, secretary; Drs. E. S. Conklin and E. B. DeBusk of the University of Oregon; Bishop Walter T. Sumner; Drs. J. Allen Gilbert and William House, both of Portland; Hon. Robert Tucker and Miss Manley of the Allen School for Defective Children; Dr. Robert E. L. Steiner, superintendent of the State Hospital for the Insane, Salem; Drs. Walter H. Williamson and Wilson D. McNary, Pendleton, and J. M. Smith.

PENNSYLVANIA

Instruction Planned.—Plans for assembling the county and other medical inspectors of the state department of health in camps during the coming summer for instructions in their duties and to learn the latest methods of combating epidemics have been worked out by State Health Commissioner Edward Martin. Special courses in sanitation will be given and lectures will be delivered by eminent specialists.

Philadelphia

Personal.—Dr. James R. Bean, Ashbourne, a suburb of Philadelphia, has been chosen health commissioner of Oshkosh, Wis., and has also been appointed director of the state cooperative laboratory there.——Dr. C. Howard Moore, who enlisted in April, 1917, went to France as a lieutenant with the Rainbow Division and was commissioned a captain in 1918, was promoted to major, March 1. and assigned to take charge of Evacuation Hospital No. 27, Army of Occupation, at Coblenz, Germany. This hospital is limited to fracture cases.

TEXAS

Health Legislation Outlined.—The special committee appointed by the governor to investigate health conditions in the state has reported its findings together with a number of recommendations. Chief among these are that the members of the state board of health be appointed, as are the regents of the university, for a term of six years, one third being appointed every two years; that there be established, in the department of health, bureaus of communicable diseases, sanitary engineers, rural sanitation, child hygiene, public health nursing and laboratories and health instruction in charge of a director; that the state be divided into eight or more sanitary health districts each in charge of a full-time district health officer; that bureau directors and health directors be appointed by the state health officer with the approval of the state board of health, and that adequate appropriations be provided with which to carry on the work of the department. The commission also reported that in west Texas there are more than 30,000 persons constantly suffering from tuberculosis and that there are more than 12,000 cases each year of typhoid fever, both of these conditions being preventable. Hookworm disease and malaria also prevail, and the state has the unenviable reputation that more than one out of every five babies born in the state die before reaching 1 year. The commission that made this report was appointed Nov. 27, 1918, and has held fifteen sessions in Austin and Dallas.

VERMONT

Personal.—Dr. Henry A. Ladd has resigned as inspector of the Vermont State Board of Health to become superintendent of the Mary Fletcher Hospital, Burlington.——Dr. Henri L. Pache, Danville, has been appointed inspector for the Vermont State Board of Health.——Dr. F. Thomas Kidder, Woodstock, has been elected president of the state board of health.——Dr. William T. Slayton, Morrisville, has been appointed a member of the state board of health, succeeding Dr. Charles S. Caverly, Rutland, deceased.

WISCONSIN

Appropriation for Influenza Fight.—The common council of Milwaukee, March 21, voted full power to Health Commissioner Ruhland to proceed against the spread of influenza, and provided him with a fund of $10,000 to be used in the educational campaign against the disease.

New Officers.—At the annual meeting of the Wisconsin Antituberculosis Association, held in Milwaukee, March 21, Dr. John W. Coon, Stevens Point, was elected president; Dr. John R. Currens, Two Rivers, vice president; Dr. J. Gurney Taylor, Milwaukee, recording secretary, and Dr. Gustave Windesheim, Kenosha, a member of the executive committee.

Personal.—Dr. Valentine A. Gudex, Milwaukee, has been appointed deputy state health officer for the fourth sanitary district, succeeding Dr. Ira F. Thompson, Eau Claire, acting assistant surgeon, U. S. P. H. S., now in charge of venereal diseases.——Dr. L. Rock Sleyster, Waupun, has been appointed physician in charge of the Milwaukee Sanitarium, Wauwatosa, succeeding Dr. Richard Dewey. Dr. Dewey will continue to reside in Wauwatosa, and will be in regular attendance at the sanatorium acting as medical director.——William Theodore K. Cradwell, Capt., M. C., U. S. Army, and formerly an associate at Milwaukee Sanitarium, will soon resume his position as assistant superintendent.——Dr. Francis A. Malone, Waterford, charged with manslaughter, has been acquitted. A car driven by Dr. Malone, who was making an emergency call, collided with another car, the driver of which suffered a fracture of the skull from which he died a short time later.——Otho A. Fiedler, Major, M. C., U. S. Army, Sheboygan, and on duty with the American Expeditionary Forces, has been transferred to Base Hospital No. 121, and promoted to lieutenant-colonel.——Dr. Arthur H. Broche, city physician of Oshkosh for eighteen years, and for six years health commissioner, has resigned.——Dr. James P. Lenfestey, DePere, has been reelected president of the DePere Health Association.——Dr. George E. Horne, Black River Falls, who has been ill for several months with rheumatism, is now convalescent.——Dr. Glenford L. Bellis, Major, M. C., U. S. Army, Wauwatosa, who had been assigned to tuberculosis work in France, has been reassigned for service in Italy.

CANADA

Personal.—Lieut.-Col. Jabez H. Elliott, M.D., Toronto, has gone to Mexico for a month's holiday.——Major John F. Burgess, M.D., Owen Sound, Ont., has been gazetted an officer of the British Empire.——Capts. Robert D. MacKenzie and A. R. Hagerman have been gazetted for the Military Cross.——Major Frank H. Pratten, Toronto, who was formerly for several years in charge of the Muskoka Free Hospital for Consumptives, is on his way home from overseas where he has been since October, 1915.

Epidemics in North Labrador.—News of the shocking conditions in North Labrador has reached St. John's, N. F., as a result of influenza, smallpox and measles which swept that coast the past winter. Earlier news showed that the deaths numbered 25 per cent. of the population. In some sections, influenza raged for four months and is said to have carried off 50 per cent. of the inhabitants. Okak, with a population of more than 200, is entirely wiped out. At Hebron over 200 died and left only a remnant to bury them. Many outposts which are invariably connected with the central mail posts have failed to report, and the conclusion is that all have perished by these diseases. Medical aid was unobtainable, and the full extent of ravages of the diseases will not be known until the opening of navigation.

Uniform Vital Statistics for Canada.—A bill has been introduced into the Ontario legislature which is the result of a plan decided on at the recent conference of public health officials at Ottawa. By it there will be provided a system of uniform registration for the dominion in the registration of births, marriages and deaths. Divisional registrars must hereafter report monthly instead of quarterly; and physicians, nurses, clergymen, undertakers and others with a knowledge of the facts will be compelled to supply information demanded by the registrar-general. There is a clause in the bill which provides that when there are births at sea, when the mother is on her way to Canada, or when births occur across the border, in hospitals, they are to be registered in the province, provided the mother is a citizen of Canada.

LATIN AMERICA

Deaths in the Profession.—Dr. **A. R. Blanco**, a prominent physician of Cartagena, Colombia, senator and leader in medical and public health matters, professor of medicine and natural sciences in the medical school of the University of Cartagena, of which he was also rector. Dr. Blanco served at times as the representative of Colombia in diplomatic negotiations in the United States and at Panama. The flags were at half mast throughout the entire department by official order the day of his funeral.——Dr. **G. Olano** of Lima, Peru, a local authority and writer on public health and medicolegal questions, aged 47.

Spanish Sanatorium in New York.—La Unión Benéfica Española of New York City is appealing for funds for the organization of a sanatorium in the neighborhood of New York City, where Spanish speaking patients will find hospital and sanatorium treatment and hear their own language spoken. It is stated that already more than $13,000 has been subscribed for the purpose. All donations should be sent to the Unión Benéfica Española (Fondo Sanatorio) 8 State Street, New York City. The union now has 2,848 members, and during the recent influenza epidemic spent over $6,000 for medical and hospital assistance of the members.

GENERAL

Health Board Meeting.—The Conference of State and Provincial Boards of Health will be held at Atlantic City, June 6 and 7, following the Conference of the Surgeon-General of the United States Public Health Service with the state and territorial health officials at Washington, June 4 and 5.

American Life Convention.—The ninth annual meeting of the Medical Section of the American Life Convention was held at the Signal Mountain Hotel, Chattanooga, Tenn., March 26 to 28. The chief topics for discussion were: "Influenza," "The Practical Significance of Important Changes in the Adult Death Rate," and "Health Conservation and Its Importance to Life Insurance." The following officers were elected: chairman, Dr. Frank L. Truitt, Indianapolis; vice chairman, Dr. George E. Crawford, Cedar Rapids, Iowa, and secretary, Dr. Frank L. B. Jenney, Chicago (reelected).

Committee to International Conference.—The American committee to the International Red Cross Conference at Geneva to be held thirty days after the signing of the peace treaty sailed for the preliminary meetings, March 15. The committee consisted of Dr. Fritz B. Talbot, Boston; L. Emmett Holt, New York, and Samuel McC. Hamill, Philadelphia, pediatricians; Col Frederick F. Russell of the Army Medical Corps; Dr. William H. Welch, Baltimore; Hermann M. Biggs, commissioner of health of the state of New York, and Dr. Edward R. Baldwin of Saranac Lake, N. Y., director of the Trudeau Foundation.

Meeting of Association of American Medical Colleges.—At the twenty-ninth annual meeting, held in Chicago, March 4, the following officers were elected for the ensuing year: president, Dr. George Blumer, New Haven, Conn.; vice president, Dr. A. C. Eycleshymer, Chicago; secretary-treasurer, Dr. Fred. C. Zapffe, 3431 Lexington Street, Chicago; chairman of executive council, Dr. Irving S. Cutter, Omaha. An entirely new constitution and by-laws was adopted, the principal differences from the old set of rules being in the requirements, high school and college premedical, for admission to medical schools. The requirement in physics was reduced to six semester hours, and in biology it was decided that six semester hours of college work were acceptable for students who had completed a year of biology in high school. The other modifications were mainly in phraseology.

Scientific Research Appropriations.—The United States Interdepartmental Social Hygiene Board announces the following appropriations from the Scientific Research Fund of the board:

Leland Stanford Junior University Medical School: (1) Investigation into more effective treatment in acute and chronic gonorrhea, under the direction of Dr. R. L. Rigdon, clinical professor of genito-urinary surgery, and Dr. Alfred B. Spalding, professor of obstetrics and gynecology, San Francisco, $2,300. (2) The permeability of the meninges to antisyphilitic drugs—an attempt to increase their permeability, under the direction of Dr. Henry G. Mehrtens, clinical professor of neurology, San Francisco, $2,300. (3) Investigation into more effective methods of treating syphilis, under the direction of Dr. Harry E. Alderson, clinical professor of dermatology, $2,600; total, $7.200.

University of Michigan, College of Medicine and Surgery: (1) A research for an improved method of demonstrating *Spirochaeta pallida* in human tissues, under the direction of Dr. Alfred S. Warthin, professor of pathology, Ann Arbor, $6,000.

Protection Against German Reinvasion of Our Chemical Industries.—The alien property custodian has conceived an idea that if German chemical patents should be placed in the hands of any American institution strong enough to protect them, a real obstacle might be opposed to German importations after the war, and the American industry might be freed from the prohibition enforced by the patents against manufacture. The organization of a corporation to be known as the Chemical Foundation, Inc., is recommended in which practically every American manufacturer will be a stockholder, but in which the number of voting shares held by any one interest will be so restricted that improper control will be impossible. It will hold the 4,500 German chemical patents, which have already been transferred to it for a consideration of $250,000. Nonexclusive licenses only will be granted to all proper American applicants at a small fee, and to the United States without fee. All surplus income is to be used for the retirement of the preferred stock and thereafter for research work looking toward the advancement of chemical and allied science and industry. The foundation has a capitalization of half a million dollars of which $100,000 is for common stock and the balance for preferred stock. After paying for the patents transferred to it, it will still have $250,000 working capital and will accordingly be in a position to prosecute vigorously any infringement proceedings which may become necessary when German manufacturers attempt to regain their American trade.

Red Cross War Council Ceases to Exist.—Mr. Henry P. Davison, chairman of the American Red Cross War Council, which was appointed by President Wilson, May 10, 1917, to carry on the work of the American Red Cross during the war, issued a statement, March 19, regarding the facts that led to the cessation of the work of the council, March 1. The war council, immediately after the signing of the armistice, instituted studies to determine when the strictly war work of the American Red Cross would be sufficiently matured to enable the directions of affairs to be assumed by the permanent staff headed by Dr. Livingston Farrand, Boulder, Colo., and this transition was made, March 1. During the past twenty-one months, donations of cash and supplies have been given to the Red Cross exceeding $400,000,000 in value, and in addition contributions of service have been given without stint and often with great sacrifice by millions of patriotic men and women. When the war opened the American Red Cross had a membership of about 500,000; at present there are more than 17,000,000 full paid members and about 9,000,000 members of the Junior Red Cross. The organization had about 9,000 person on its rolls in France, and of these the services of 6,000 are still being required. Their active operations are still in progress in Archangel and in Siberia. A commission has been dispatched to carry supplies and to work in the Balkan countries, a second commission has just reached Poland equipped with physicians and nurses, medical supplies and food for children and invalids; a third commission has been appointed to aid the relief of the suffering of Russian prisoners in German prison camps, and a fourth commission is working in Palestine.

Fellowships for Physics and Chemistry.—The National Research Council has been entrusted by the Rockefeller Foundation with the expenditure of an appropriation of half a million dollars within the period of five years, to promote fundamental research in physics and chemistry in educational institutions in the United States. The primary feature of this project is the initiation and maintenance of a system of national research fellowships, which are to be awarded by the council to persons who have demonstrated ability in research to enable them to take investigations at educational institutions to make adequate provision for the effective prosecution of research in physics and chemistry. Among the important results expected to follow from the execution of the plan are: opening of a scientific career to a larger number of able investigators and their more thorough training in research; increase of knowledge regarding the fundamental principles of physics and chemistry, and creation of more favorable conditions for research in the educational institutions of this country. The project will be administered by the research fellowship board of the council, which is composed of Henry A. Bumstead, professor of physics in Yale University; Simon Flexner, director of the laboratories of the Rockefeller Institute for Medical Research, New York; George E. Hale, director of Mount Wilson Observatory; Elmer P. Kohler, professor of chemistry, Harvard University; Robert A. Millikan, professor of physics, University of Chicago; Arthur A. Noyes, director of the Research Laboratory of Physical Chemistry, Massachusetts Institute of Technology, and Wilder D. Bancroft, professor of physical chemistry, Cornell University. The research fellowships will be awarded to persons who have had training at an American university or scientific school equivalent to that represented by the doctor's degree. The salary will be ordinarily $1,500 for the first year. The appointment will be for one year, with eligibility for successive reappointments usually with an increase in salary. It is expected that fifteen or twenty fellowships will be available this year. Applications should be sent to the secretary of the Research Fellowship Board, National Research Council, 1023 Sixteenth Street, Washington, D. C. Applications will be received up to Sept. 1, 1919, for fellowships available during the coming academic year, but a limited number of appointments will be made on the basis of applications made before April 20, this year.

FOREIGN

War Mortality Among German Physicians.—The *Hospitalstidende* quotes a Berlin medical journal of last November to the effect that the latest casualty lists bring to 663 the number of physicians killed in the war; 422 died from illness; 212 were taken prisoner and 72 are missing.

Ruggi and Durante Reach the Age Limit.—The two widely known surgeons, Dr. G. O. Ruggi of Bologna and Dr. F. O. Durante of Rome, reach the age limit this spring and retire from the chairs of clinical surgery and operative medicine in their respective universities. Durante, with Baccelli, founded the *Policlinico* twenty-six years ago.

Proposed Cancer Hospital in Norway.—The *Ugeskrift for Læger* relates that the Norwegian Cancer Fund Committee has collected 600,000 kronen (approximately $150,000) toward a national hospital for care of and research on cancer. Some funds from another source are soon to be available, and the second week of February a general appeal by cards is to be made throughout the country, and in Christiania a lecture on cancer is to be held, and some concerts. The aim is to provide an institution where the inoperable cases can get radiotherapy, etc.

Old Nomenclature Preferred.—The Anatomical Society of Great Britain and Ireland, at its meeting in London, March 1, received and unanimously adopted the report of its committee on nomenclature, "That it sees no reason for departing from the use of the old nomenclature as the recognized medium of description for employment in anatomical textbooks and departments, or by medical men in general; on the other hand, it thinks that there are very good reasons to be urged against the adoption of any other nomenclature for this purpose."

Red Cross Work in Siberia.—The American Red Cross has opened a well-appointed hospital four versts (2½ miles) from the city of Omsk, Siberia, with 400 beds and capable of extension to 1,000. This hospital is one of the series of medical institutions which have been organized in Siberia, chiefly through the efforts of Dr. R. B. Teusler of Tokyo, chairman of the Red Cross Commission to Serbia.——The American Red Cross has opened a hospital at Tumen with accommodations for 500 patients; also dental clinics at Cheliabinsk and at Ekaterinburg. A hospital has also been opened at Petropavlovsk for typhus fever with a capacity of 400 beds.

Deaths in the Profession Abroad.—Dr. **H. Chaput,** head of a surgical clinic at the hôpital Lariboisière, Paris, aged about 56.——Dr. **F. de Cortejarena,** of Madrid, aged 83. He was one of the founders of the Sociedad Ginecologica in 1874, and was professor of obstetrics and pathology at the University of Madrid for many years, chief at one time of the Public Health Service, delegate to many international medical congresses, and representative in the senate of the Academia de Medicina and the province of Madrid, and was long on the editorial staff of the *Siglo Medico.* On the occasion of his fiftieth professional anniversary, he published his memoirs under the title "Tiempo Pasado."——Dr. **G. Sterzi,** professor of comparative anatomy at the University of Cagliari. His published works dealt mainly with the comparative anatomy of the nervous system.——Dr. **O. V. Lassen,** a prominent surgeon of Denmark, aged 74.——Dr. **S. H. A. Rambusch** of Copenhagen, aged 57.——Dr. **G. Pandolfi,** associate professor of nervous and mental diseases at the University of Naples, editor of the *Annali di Neurologia.* His death while in military service has recently been confirmed.

MEXICO LETTER

Mexico City, March 24, 1919.

An Alcoholic Inundation

On account of the approaching nation wide prohibition of alcohol manufacture in the United States, some of the brewers and distillers of the United States have been studying whether they could move their plants to Mexico, establishing breweries and distilleries in Mexico City and elsewhere. We are by no means behind other nations in the matter of alcoholism, and if we could count on having an abundant, well distilled and comparatively inexpensive drink, like beer, it might induce those who drink pulque (the fermented juice of the agave cactus) to take in its place a less harmful beverage. Pulque, in addition to its noxious action from the large content of alcohol, is harmful further from the putrefied substances which it contains and the large number of *living microbes in it.* For a long time, distinguished clinicians have been attributing to the abuse of pulque the prevalence of affections of the digestive apparatus in the central tableland of Mexico, as also the frequency of dysentery and of abscess in the liver. As we know now the important rôle played by *Endameba histolytica* in these last mentioned processes, it is not at all venturesome to assume that the white liquor supplies a predisposing factor at least, and may in certain cases be the vehicle for the amebas. The contamination may occur in the fluid itself, or from contact with the hands and lips of the workmen or in the *cueros* in which it is usually kept.

"Education Will Make a New Mexico"

John Emerson Smith, director of the San Antonio *Express* and the weekly *Evening News,* has been visiting the various departments of the university here. He has collected data for an article to be published in his journals under the above heading, analyzing the workings of the administrative functions and the intellectual progress of our seats of learning. His object is mainly to make known in the United States the progress of Mexico in all that refers to university instruction and the public schools.

The Academy of Medicine

The Academia de Medicina announces that there are some vacant places in the sections of medical natural history, bacteriology, internal medicine, hygiene and pathologic anatomy, and invites those who would like to compete for the vacant posts to present the necessary credentials. Dr. T. G. Perrín, a Spanish physician resident here for some years, applied for the post in the section on pathologic anatomy, presenting therewith a monograph on the cytodiagnosis of syphilis, based on 200 cases. His article made a favorable impression, and this with his scientific antecedents, insured his acceptance. Dr. J. Arroyo, collaborator in Dr. Perrín's laboratory and professor of histology in the medical school here, is soon to present a report on the Lange colloidal gold reaction in the diagnosis of syphilis of the nervous system.

The Medical School

The courses in English and French are only now under way in the Facultad de Medicina although these courses were inaugurated last year. The course in French is in charge of Madame Facio, from Paris, and the English course is to be taught by Sr. T. Montaño, a graduate of a London college. Dr. F. Ocaranza has begun a course on biology (*curso libre*), and a course in German has been established, with biweekly classes. The gymnasium for the students will soon be conveniently installed according to the notice sent out by Dr. R. Amor, director of the Facultad, so that the students can cultivate their physical strength along with their mental faculties and thus will obtain a harmonious all-around development.

Welfare Work

A number of charitable persons are contributing cash or clothing for children to aid in the work of the *Sociedad* Protectora del Niño, which aims to aid homeless and friendless children. There is a wide field for such work here.

A group of Mexicans living at Los Angeles, Calif., have formed an association to collect a fund to aid needy persons there with clothing and medicines. Two physicians, Drs. J. M. Samaniego and F. Zarraga, are on the board of the society, which is under the patronage of the mayor of Los Angeles.

Personal

Dr. P. Sosa has been appointed professor of hygiene in the naval school, the Escuela Naval, recently reinaugurated at Vera Cruz.

Dr. J. A. Pérez, director of the Hospital Morelos has returned from New York where he went on official business, to purchase medicines and surgical instruments, the cost totaling about $85,000.

PARIS LETTER

PARIS, March 2, 1919.

Infectious Diseases and Prophylaxis in the Army

At the second meeting of the Société de biologie, devoted to the biology of the war, Dr. Louis Martin discussed the subject of diphtheria carriers. He described the technic employed in searching for carriers and the examination of diphtheria bacillus colonies. As to the contagiousness of the disease, he found that the patients are the most important carriers. They harbor the most virulent bacilli, the mucous membrane of the throat furnishing the greatest number of colonies in serum swab cultures. Successive cultures contain progressively fewer colonies in proportion to the interval since the beginning of the disease. As a rule, in two thirds of the cases at least, the bacilli disappear completely one month after the onset of the disease. They may, however, be found for a long time afterward, for three and even six months, but such instances are very rare. The impending disappearance of the bacilli is shown by the lessening of the number of colonies; diminution in virulence, and association of other bacteria with the diphtheria bacillus. As the colonies of the latter become fewer in number, an increasing number of staphylococci is seen.

Carriers should be sought for in the neighborhood of the patient. They are classified as "recent," that is, persons who have contracted diphtheria from another patient. The "old" carriers are met with among persons in environments long contaminated with diphtheria. These "old" carriers have apparently normal throats, so far as appearances go; the mucous membranes are healthy, and they do not contract the disease. They can, however, spread it. They are known as "healthy" carriers. As a rule, the diphtheria bacilli do not disappear suddenly and definitely from the throat of carriers; a culture taken today may not show any bacilli, whereas a culture made several days later may show large numbers of bacilli. Therefore, it is held that such persons will be declared not to be carriers only after two negative cultures, made at six days' interval. A simple angina may be the occasion for the return of the bacilli in culture, even in large numbers; often they then disappear rapidly and definitely.

As to prophylaxis: Isolation of the patient is of prime importance, because he is the most formidable carrier; he is the principal cause of all epidemics. Whenever a case of diphtheria makes its appearance in a unit, the doctor should at once make an investigation of persons in the environment of the patient, isolate all persons who have buccopharyngeal lesions, and, if necessary, inject them with antitoxin. Disinfection is very essential after a case of diphtheria, more so when many cases have existed, for removing the carrier would not prevent the spread of the disease. Prophylactic injections of antitoxin should be given, especially when the epidemic is very grave and when the disease develops very rapidly.

Dr. Charles Dopter, physician in chief of the army, and professor of epidemiology in the Ecole d'application de médecine et de pharmacie militaires du Val-de-Grâce, reported on meningococcus carriers in the zone des armées during the war. At the beginning of the war the medical officers anticipated during the first winter and spring a considerable number of cases of cerebrospinal meningitis, as its development would be facilitated by the bringing together of large military organizations. But nothing of the kind occurred, strange to say; and now, after four years of war, it may be said, on the basis of the published figures, that meningococcic infection was one of those which seemed the most negligible in the zone of the armies. These figures are as follows: In 1915, there were 1,075 cases of cerebrospinal meningitis; 452 cases in 1916, and 406 cases in 1917.

From these statistics it appears that the total number of cases observed in the active forces is quite inconsiderable. In fact, it is worth noting that compared with the incidence of meningitis among the troops quartered in the interior the foregoing record is only one fourth as high. Cerebrospinal meningitis appeared in the army only in a sporadic manner, striking here and there a very few of the military men out of very large units, so that it has been impossible to connect up the various outbreaks so few and far apart have they been. However, several outbreaks did take on an epidemic character. In several instruction camps in which men were crowded together in the restricted area of cantonments, where there was not room to give them sufficient freedom of movement, Dopter had an opportunity of observing several foci which sprang up suddenly, six or eight cases appearing inside of forty-eight hours, extending even to the neighboring units so that there was an evident relation to the groups first attacked. What is true of cerebrospinal meningitis as a disease is equally true of the carriers. Just as the disease itself does not spread but remains localized, so the meningococcal infection in the carriers is only revealed by a rhinopharyngitis which remains localized in one spot where the pathogenic germ fortifies itself without reaching out and attacking other organs.

Prophylaxis should consist in isolating meningococcus carriers, whether ill or not, so as to protect the unit involved against possible contagion from them. This specific complete prophylaxis may be accomplished as follows: When the first case of meningitis is seen (1) isolate everyone around who can be suspected until the exact nature of the causative organism has been determined; (2) if it is the meningococcus, take cultures with a view to isolating the carriers and making such bacteriologic examinations as will detect these carriers; (3) isolate known carriers until the germs have disappeared from the rhinopharynx; treat them by means of local antiseptic applications to the nasal fossae. This program seemed hardly possible to carry out thoroughly in war times; nevertheless, it was done at all points. This prophylaxis of meningococcus rhinopharyngitis was rendered easier of course by the slight extension of the epidemic meningococcus element. It is possible that the extension of the disease may have been prevented in part by the measures applied, especially by the activity of the army laboratories.

Prophylaxis Against Rabies

The Académie de médecine recently discussed measures for combating the increase in the number of hydrophobia cases which has been noted in all parts of France since the beginning of the war. The discussion was participated in by Drs. Kirmisson, Railliet and Bard, and a resolution was adopted urging that (1) the attention of legislators and the authorities be called to this health problem of manifest and progressive gravity; (2) that all cities as well as country districts use all possible means to impound all dogs which are roaming around at large; (3) an earnest appeal be made to the public in general to cooperate to the fullest extent to help to eradicate rabies. Placing a license tag on the dog has yielded good results in other countries as well as in certain French cities, therefore it should be made obligatory, as establishing the responsibility of the owner of the dog.

Aeroplane Transportation of Wounded in Sahara

Dr. T. Tuffier recently detailed to the Académie de médecine the services rendered by the aeroplane in the transportation of the severely wounded and of medical officers called to care for them in south Oran, Morocco, and in south Tunis. The organization in charge of this work established an aerial route extending 597 kilometers into the desert. Landing stations and food depots were established along this route. Dr. Tuffier stated that to facilitate the handling of the wounded, these aeroplanes should open at the side, and they should be supplied with Bréguet's apparatus so as to make them as rapid as possible and give them greater stability in making a landing. Besides the aeroplane ambulances, which should be reserved for the cases of severe wounds of the thorax and abdomen and of the legs, reconnoitering and bombing aeroplanes can be used to carry the less severely wounded. In the Sahara the only really serious obstacles which the aeroplanes had to overcome were caused by the temperature, which determines the dangerous air currents and eddies in the strata of superposed and overheated air, and the sirocco, because of the sand clouds which this wind raises.

Influenza Epidemic

The epidemic of influenza which had declined has broken out anew in a most disquieting manner. In view of the increase in the number of the sick, the Assistance Publique has taken measures to meet the increase in the number of hospital admissions (an average of 240 per day): 200 beds have been set aside at the Salpêtrière, 200 at the hôpital des Petits-Ménages, and 180 at the hôpital Cochin. The epidemic has assumed grave proportions not only in Paris but in several of the départements.

Plans of the Paris Medical School

The Paris medical faculty held a reunion February 22 for the demobilized students who have been released from the army so that they can take up their medical studies. These students are members of the classes preceding the 1914 class; they have seen fifty-four months of military service, some of them having been in the service before the declaration of war. The Faculty has established special didactic and practical courses for these students, providing for intensive teaching which will shorten the annual course to six months without interfering with the general courses of instruction.

Medical Officers Victims of Professional Duty

The medical group in the parliament has passed resolutions calling on the ministers of war and marine to consider medical officers who died while on service in military or naval hospitals as having fallen on the field of battle. The battle-field of these men was the hospital in which they served, therefore all honors of having fallen while fighting should be accorded them, as is done in the case of combatants in the line.

LIMA LETTER

Lima, Peru, Feb. 28, 1919.

The Pandemic of Influenza

First Lima and then the rest of Peru had and are still suffering from the ravages of the pandemic of influenza. Statistics show that in the capital of the republic the mortality from this cause trebled the total mortality during the months of November and December. More than 600 deaths can be attributed to influenza, and the total mortality for the year was thus raised from 5,000 to 6,500. The symptomatology, epidemiology and the course of the epidemic do not differ from those reported elsewhere throughout the world. At the same time it may be noted that the second outbreak of the epidemic, with its grave and bronchopulmonary forms, did not spread at Lima to the same extent as at other points. Perhaps during the first cycle, which was of a benign and catarrhal form, almost the entire population had been attacked and immunized.

The Academy of Medicine

The Academia Nacional de Medicina has recently elected to regular membership Dr. O. Hercelles, professor of pathologic anatomy and chief of the Laboratorio de Investigaciones Clinicas of the Hospital 2 de Mayo, and also Dr. A. Corvetto, in charge of the Dispensario antituberculoso Byron. The Academia has also elected to membership three physicians recently banished from Chile where they had been practicing at Iquique. The reason for the banishment is that they are natives of Peru. Dr. M. Alcedán was elected to regular membership, and Drs. Neuhaus and Parodi to associate memberships. This act is as a protest against the arbitrary procedure of the Chilean government.

The Spanish Edition of The Journal

The appearance of the Spanish edition of The Journal has been welcomed at Lima with marked favor. It is regarded as a decisive advance on the road of friendship and close scientific relationship between North and South America.

Relapsing Fever at Lima

Dr. Zevallos recently encountered a case of relapsing fever in the San Bartolomé military hospital. The subject was a soldier who had not been away from Lima for many months. This discovery demonstrates the existence of relapsing fever in our midst. The patient presenting the disease was treated with arsphenamin, a clinical cure following a dose of 0.45 gm.

Reform in the Care of the Insane

A philanthropist here, Don V. L. Herrera, has presented the medical staff of the Magdalena Colony Asylum for the Insane with the sum of 20,000 libras to be devoted to the transformation of the care of the insane. The gift has been accepted by the authorities in charge of the institution, the Sociedad de Beneficencia of Lima. The projected reforms have met with the opposition of the sisters of the St. Vincent de Paul order who have had charge of the institution. The conflict has not yet been settled, and it seems inevitable that the sisterhood will withdraw from the work entirely. The affair is creating much discussion among the public generally and in scientific circles.

The Public Hospitals, Etc., of Lima

The Sociedad de Beneficencia of Lima in its various hospitals and asylums cared for 19,519 needy persons January to November, 1918. There were 2,394 deaths among them. The total expense was 85,400 gold libras. A Peruvian libra is almost $5. The dispensaries were visited by 80,410, including 28,919 first-time applicants, and medicines were dispensed without charge 108,718 times.

LONDON LETTER

London, March 12, 1919.

The Influenza Epidemic

Influenza continues to claim many victims, especially in Scotland, the North of England, and the Midlands. In the last weekly record there were 580 deaths from influenza and pneumonia in Glasgow, the highest record in the city's death rate, being 50 per thousand per annum. The number of deaths from the disease in Manchester last week was 191 in addition to sixty-three deaths from pneumonia and seventy-eight from bronchitis. In Leeds last week, 127 deaths were due to influenza as compared with eighty-one the previous week. In Birmingham last week there were 157 deaths, and the death rate was 31.6, as against the normal rate of 12. The total deaths numbered 527, a considerable increase. Elementary schools and nurses have responded to the call for help, and more are wanted. The Huddersfield Corporation has given notice that the Local Government Board has ordered that influenza shall be deemed an infectious disease. All the elementary schools in the Colne Valley have been closed for a fortnight. In Dublin the epidemic is spreading. Last week the deaths from the disease in the city numbered 143, an increase of sixty-three on the previous week. It has been decided to close the Mansion House to concerts, meetings and lectures until the disease has abated.

At a conference held at the Institute of Hygiene, Sir Malcolm Morris, the president, criticized the recommendations of the Local Government Board The solution of common salt and potassium permanganate recommended for washing the nostrils and throat he described as a horrible mixture. He had found a solution of colloidal silver beneficial. Sir St. Clair Thomson said the disease was splashed on us by persons talking, laughing, coughing and sneezing at anybody within 10 feet of them. Persons known to have the disease should be isolated, not only entirely but also locally, by making them wear veils when anybody came near them, and those in attendance on them or those who risked being near them should also wear masks or veils. Persons who in an omnibus or tube coughed without putting up their hands, or sneezed without putting up their handkerchiefs, should be prosecuted for indecency. He was inclined to think youth and fitness predisposed to the disease. In a sanatorium which he visited regularly, the consumptive patients had contracted influenza in a much milder form than their healthy attendants. But the possibility of other causes besides differences of pulmonary condition contributing to this result had to be taken into account. People might be working in an open-air sanatorium without believing in open windows for themselves. A nose in a healthy condition he did not think there was any need to wash out. He was opposed to the use of potassium permanganate or any other irritating antiseptic. The type of the influenza epidemic was certainly changing.

A government report on influenza in India states that the first influenza epidemic in Bombay city was in June last, and was responsible for more than 1,600 deaths. A subsequent virulent outbreak occurred in September, October and early in November, during which period the mortality in Bombay city exceeded the normal by 14,678. Besides bacteriologic investigation, relief measures consisted of treatment in hospitals, house-to-house visitation, supply of free milk, woolen jackets to prevent pneumonia, opening of roadside dispensaries in several wards, and supply of free medicine.

The Danger of the Spread of Lice and Itch After Demobilization

Apprehension has been felt as to the spread of lice and itch among the civil population as the result of demobilization, with consequent spread of lice-borne diseases. The Local Government Board has communicated with the Army Council on the subject and has been informed that special and thorough arrangements have been made by the army authorities, both abroad and at home, for cleansing, bathing, disinfestation, issue of clean clothing and like measures, to be undertaken systematically before the men return to their homes on leave or on discharge. Should health officers learn of instances in which men thus returning on demobilization to their homes remain infested with vermin, the facts should be communicated to the board for their information and that of the war office. The two departments are cooperating to obtain all possible information as to the occurrence of infectious diseases among the men returning to this country.

The British Association of Radiology and Electrotherapy

A new society, the British Association of Radiology and Electrotherapy, of which Sir James Mackenzie Davidson is president and Dr. Knox and Dr. Cumberbatch are secretaries, has been formed. It is felt that the time has come to place the teaching of radiography on a sounder basis, and that the many ill-qualified persons who have been carrying on radiographic work should be discountenanced. Membership is limited to qualified physicians and dentists and to others whose qualifications and scientific attainments are considered satisfactory to the committee. The society has approached the University of Cambridge with a view to granting a diploma after examination in radiology and electrotherapeutics. Meanwhile, representations have been made to the medical schools in London and the provinces, with the object of providing the necessary teaching of the subjects for the examination of the diploma. It is also proposed to establish postgraduate courses of study and research, and to create a British school of radiology and electrology. This, it is hoped, will be coordinated with other similar schools throughout the world.

A Martyr to Science

Major H. G. Gibson, Royal Army Medical Corps, who in conjunction with two other workers, Major Bowman, Canadian Army Medical Corps, and Captain Connor, Australian Army Medical Corps, apparently made the important discovery published in the *British Medical Journal* of Dec. 14, 1918, that the influenza germ is a filter-passer, has fallen a victim to the very virulent strain of the germ with which he was experimenting. He caught the disease and succumbed to pneumonia. A career of great promise has closed. Educated at Guy's Hospital, he joined the army medical corps in 1907. In 1914 he joined the "specialist class" in bacteriology and made the highest marks in the examination which followed. When the war broke out, he left his scientific work for active service in France, where he was severely wounded by a shell. He recovered, but was unfit for active service and was appointed to the vaccine department of the Royal Army Medical College. He devoted himself to research on protection against bacillary dysentery which culminated in the production of his antidysenteric serovaccine. The reports on this remedy have been favorable, though it is too soon to state its final position.

Lectureships on Children's Diseases

At the Royal Hospital for Sick Children, Great Ormond Street, two lectureships on children's diseases have been founded by private donors, who have each given a sum of $25,000. This will be the first occasion of holding special lectureships on diseases of children. It is laid down that the lectures shall be both systematic and clinical, and that the lecturers shall be respectively a visiting physician and a visiting surgeon to the hospital in the wards of which the clinical instruction shall be given. The medical lecturer is to have "a consultative connection" with the Royal Maternity Hospital so that children born there and requiring medical or surgical treatment may be brought directly into touch with the hospital.

Marriages

Thomas Perrine Edmundson, Lieut., M. C., U. S. Army, Pittsburgh, to Mlle. Raphaelle Degeunes of Paris, France, February 24.

William Barclay Parsons, Lieut., M. C., U. S. Army, New York City, to Miss Rose Saltonstall of Boston, March 22.

S. Brock McGeorge Dear to Miss Marjorie Pohle, both of the Bronx, New York City, March 15.

Roland Ferdinand Wear to Miss Jane Mae Thrall, both of Williamsport, Pa., March 22.

Morris Leff to Miss Miriam G. Kramer, both of New York City, February 11.

Deaths

Abel Fitzwater Price ⊕ Commodore, Medical Director, U. S. Navy (retired), Sandwich, Mass.; University of Pennsylvania, Philadelphia, 1868; aged 71; fleet surgeon for Admiral Dewey in the battle of Manila Bay in 1898; who entered the Navy, Nov. 10, 1868, and was retired, Dec. 13, 1909, after thirteen years and ten months of sea service on attaining the age of 62 years; died in a hospital in Springfield, Mass., March 22.

James Forrest Todd, Chicago; Bellevue Hospital Medical College, 1863; aged 78; physician of Cook County and physician in chief for the Detention Hospital for the Insane in 1889, and city physician of Chicago, and physician in chief of the Infirmary of the House of Correction and Smallpox Hospital in 1893 and 1894; died at his home, March 24, from cerebral hemorrhage.

George Washington Goins ⊕ Lieut., M. C., U. S. Army, Tooele, Utah; Marion Sims College of Medicine, St. Louis, 1898; aged 47; a specialist on diseases of the eye, ear, nose and throat; who entered the Army in November, 1918, and was stationed at Jefferson Barracks, Mo.; died at Jefferson Barracks, March 14.

Lionel Andrius Anderson ⊕ Lieut., M. C., U. S. Army, St. Paul; Washington University, St. Louis, 1916; aged 31; a specialist in roentgenology; assigned to duty with the British Army Medical Corps; died in Namur, Belgium, February 17, from pneumonia following influenza.

Robert Goldthwaite ⊕ Capt., M. C., U. S. Army, Montgomery, Ala.; Bellevue Hospital Medical College, 1893; aged 46; on duty with the American Expeditionary Forces in France; died in Base Hospital No. 26, Allery, France, September 30, from meningococcus meningitis.

Frank Reader Rix, Flushing, N. Y.; Harvard Medical School, 1879; aged 65; for eighteen years supervisor of musical education in the public schools of Manhattan borough; died in the New York Skin and Cancer Hospital, New York City, March 16.

George W. Kunz, New York City; Bellevue Hospital Medical College, 1887; aged 54; assistant surgeon to the New York Eye and Ear Infirmary; and attending otologist to the St. Bartholomew's Clinic; died in Lenox Hill Hospital, March 4, from pneumonia.

James Moore King ⊕ Chewalla, Tenn.; University of Nashville, Tenn., 1896; aged 65; professor of chemistry and clinical dermatology and secretary of the medical department of his alma mater; was struck by a train, January 5, and killed.

William A. Cochran, Danville, Ill.; Medical College of Ohio, Cincinnati, 1873; aged 68; physician of Vermilion County for seven years; died at the home of his son in Perrysville, Ind., March 16, from cerebral hemorrhage.

James Woods, Schuyler, Neb.; Western Reserve University, Cleveland, 1870; aged 74; at various times physician of Schuyler and Colfax County; a veteran of the Civil War; died at his home, March 12, from arteriosclerosis.

Bennie Logan Englerth ⊕ Lieut., M. C., U. S. Army, Anna, Ohio; Eclectic Medical Institute, Cincinnati, 1915; aged 25; on duty with the American Expeditionary Forces in France; died in France, December 16, from pneumonia.

Emmet James Stewart, Cumberland, Md.; University of Maryland, Baltimore, 1914; aged 37; a member of the Medical and Chirurgical Faculty of Maryland; died at his home, January 28, from pneumonia following influenza.

William J. S. Stewart, Act. Asst. Surg., U. S. P. H. S., Caracas, Venezuela; University of Virginia, Charlottesville, 1891; aged 52; surgeon in the Army transport service during the war with Spain; died in Caracas, March 11.

Martin Luther Mench, Jersey Shore, Pa.; University of Pennsylvania, Philadelphia, 1866; aged 73; a member of the Medical Society of the State of Pennsylvania; died at his home, February 17, from cerebral hemorrhage.

Albert N. Richardson, Chicago; Rush Medical College, 1872; aged 77; for eighteen years a quarantine physician in the health department; died suddenly, March 24, from heart disease, while making a professional call.

Carl Cleveland Smith ⊕ Lieut., M. C., U. S. Army, Akron, Ohio; Ohio State University, Columbus, 1911; aged 32; on duty with the 37th Division, American Expeditionary Forces in France; died in France, February 17.

⊕ Indicates "Fellow" of the American Medical Association.

John F. Kirkpatrick, London, Ohio; College of Physicians and Surgeons, Keokuk, Iowa, 1876; aged 69; a member of the Ohio State Medical Association; died at his home, March 12, from pneumonia following influenza.

James N. Mendenhall ⊕ Plano, Texas; University of Maryland, Baltimore, 1880; aged 61; formerly clinical professor of medicine in Baylor University College of Medicine, Dallas, Texas; died at his home, March 3.

Max Landesman, New York City; Medical College of Indiana, Indianapolis, 1892; aged 55; a member of the Medical Society of the State of New York; died at his home, March 16, from arteriosclerosis.

William Ernest Barker ⊕ Chanute, Kan.; American Medical College, St. Louis, 1878; aged about 73; for a time treasurer of the Kansas Medical Society; died at his home, March 13, from cerebral hemorrhage.

James Thomas Meehan, New York City; New York University, New York City, 1882; aged 59; a member of the Medical Society of the State of New York; died at his home, March 16, from heart disease.

Lucius Thomas Ingham, Lee, Mass.; Bellevue Hospital Medical College, 1886; aged 64; died in the House of Mercy Hospital, Pittsfield, Mass, March 15, two days after an operation for abscess of the neck.

James Parker Blunk, Ottawa, Kan.; Ensworth Medical College, St. Joseph, Mo., 1900; aged 44; a member of the Kansas Medical Society; died at his home, March 18, from pneumonia following influenza.

Lucy N. Tappan, Urbana, Ohio; Woman's Medical College of Pennsylvania, Philadelphia, 1886; aged 71; for twenty-seven years an instructor in her alma mater; died at her home, March 15.

Theodore D. Finck ⊕ Louisville, Ky.; Kentucky School of Medicine, 1882; aged 56; died in the Norton Memorial Infirmary, Louisville, March 22, from septicemia due to an infected finger.

George Everett Herchel, Mechanicsville, Iowa; Loyola University, Chicago, 1916; aged 28; died in the University Hospital, Iowa City, March 17, a day after an operation for appendicitis.

Loving Flint Hubbell, Sidney, Ohio; Starling Medical College, Columbus, Ohio, 1901; aged 42; a member of the Ohio State Medical Association; died at his home, March 9, from pneumonia.

STEVENS CONSUMPTION CURE

A Discredited London Quack Attempts to Exploit Canadian Veterans

The Journal has received the following letter from Dr. J. H. Holbrook, physician-in-charge of the Mountain Sanatorium for the treatment of pulmonary tuberculosis at Hamilton, Ont.:

> "We are treating returned tuberculous soldiers, who are receiving 'literature' from Chas. H. Stevens of 204-206 Worple Road, Wimbledon, London, S.W., and some of our men are being duped into sending their money to him for treatment.
>
> "We have tried to warn them that they are wasting their money, but we have no definite information on the matter and if you can furnish us with any of the particulars, we would be greatly obliged in the interest of our patients. We have a booklet giving extracts from the medical evidence given in the consumption cure libel actions, by Stevens, against the British Medical Association, and know that there must be considerable information available."

Profitable quackery dies hard and quackery of the "consumption cure" type is peculiarly profitable. For years C. H. Stevens has been in that most disreputable of businesses—exploiting the consumptive.[1] He was shown up by the London *Truth* years ago, and brought suit for libel against that publication—without obtaining, however, any satisfaction. His nostrum has been exploited in South Africa, England and the United States. It was analyzed by the chemists for the British Medical Association, and the method of exploitation exposed in the British Medical Association's book, *Secret Remedies*. This was in 1908. After waiting three years, Stevens sued the association. At the first hearing in 1912, the jury failed to agree; at the second hearing in 1914, the jury declared that the association's strictures were not libelous but fair comment. Stevens then appealed the case—and again lost.

CRUSADE AGAINST CONSUMPTION.

Greatly reduced facsimile of a portion of a large advertisement of "Sacco" in a London paper in 1910.

The analysis made by the British chemists showed the stuff to contain no active drugs except alcohol, of which there was over 23 per cent., and glycerin, of which there was less than 2 per cent. The estimated cost of the ingredients of a bottle

---

1. The Journal has discussed this man's business at various times. See issues of Sept. 3, 1910; April 5, 1913; Sept. 12, 1914; June 12, 1915.

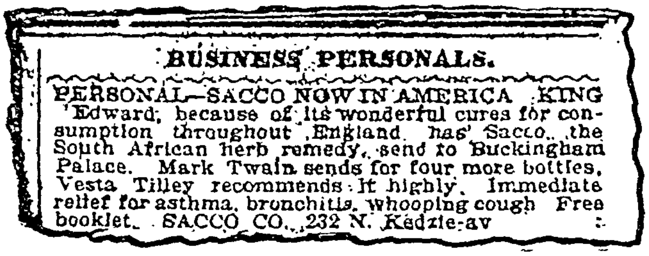
of Stevens "consumption cure" was 3 cents; it sold for $1.25. Stevens published what he termed a "formula" for his nostrum, thus:

> "Its formula is 80 grains of Umckaloabo root and 13¼ grains of Chijitse to every ounce, prepared according to British Pharmacopeia method."

Making a pretense of frankness by glibly giving meaningless names evolved from a fertile imagination is a scheme as old and as unscrupulous as quackery itself. But the unknown may always be counted on to inspire awe and Stevens' crude deceit still seems to be a financial asset.

THE "WONDERFUL NATIVE HERB" HUMBUG

Nor was the "formula" the only piece of theatrical claptrap worked by. Stevens. He claimed to have learned of "Umckaloabo" while in South Africa some years ago where he went because he had consumption. While in Basutoland he lived in a tent and partook of a decoction of a native root "Umckaloabo"—given him by a kafir! Needless to say, it cured him! The commercial possibilities of "Umckaloabo" appealing to Stevens he went to Capetown, South Africa, where he put the stuff on the market under the name of "Sacco"—"Stevens African Consumption Cure, Original"—doing business under the trade name of "Sacco, Limited." Capetown was a verdant field for Stevens made a large amount of money while there, and opened a branch office in London. At a time that he was clearing a net profit of $15,000 a year, he got into the courts and found it expedient to leave Capetown.



BUSINESS PERSONALS.

PERSONAL—SACCO NOW IN AMERICA KING Edward, because of its wonderful cures for consumption throughout England, has Sacco, the South African herb remedy, send to Buckingham Palace. Mark Twain sends for four more bottles. Vesta Tilley recommends it highly. Immediate relief for asthma, bronchitis, whooping cough Free booklet. SACCO CO., 232 N. Kedzie-av

Facsimile (slightly enlarged) of an advertisement of "Sacco" that appeared in a Chicago newspaper in November, 1908. In spite of the fact that Vesta Tilley, King Edward and Mark Twain were all said to be greatly impressed with the marvel, "Sacco" failed to get a foothold in Chicago.

"SACCO" BECOMES "LUNGSAVA"

He then went to Johannesburg, where "Sacco" was rechristened "Lungsava," and was sold by Stevens under the imposing trade name "South African Institute of Medicine." While here he added to his nostrum another unheard-of herb, which he called "Chijitse." Johannesburg seems to have taken to the nostrum, but after being twice convicted of violating the laws governing medical practice, Stevens left South Africa and went to England, where he located in Wimbledon, a London suburb. Here he began pushing his stuff under the old name, "Sacco."

AN INTENTIONAL FRAUD

In 1910 while at Wimbledon, Stevens was sued by a widow for $50, the sum promised by Stevens in his advertisements, to any patient whom he did not cure of consumption. The plaintiff's husband relying on Stevens' nostrum, of course, died. In giving judgment for the payment of $50 to the widow the judge thus expressed his opinion of Stevens and his "cure":

> "I will now say what I think and what I had abstained from doing before. I think this is an intentional and well-considered fraud. It is a scandalous thing that poor people should be imposed upon and led to part with their money, and to hope that those dear to them would be cured, by those processes which were nothing but quack remedies, and had not the slightest value of any kind."

In spite of the judge's eminently just characterization of Stevens and his business, this quack had the effrontery to bring suit against the British Medical Association a year later—in 1911, with results that have already been mentioned. Stevens, in his appeal to the higher courts, after losing the case, attempted to make much of what he claimed was the personal nature of the attack on him by the British Medical Association. One of the judges of the appellate court, however, pointed out that a comment may be fair even though it contains a personal attack, this rule having been clearly stated by Lord Atkinson in the classic case of *"Dakhyl* v. *Labouchere"* (1908, 2 K.B., 329), which was carried to the House of Lords in 1908, where it was laid down that:

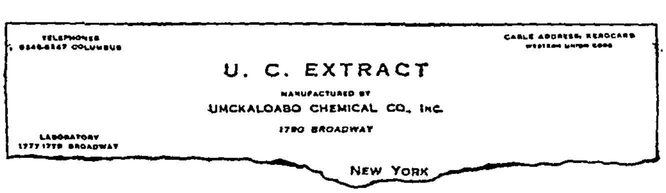
> "A personal attack may form part of a fair comment upon given facts truthfully stated, if it be warranted by those facts."

The "Sacco Co.," London, of the original Capetown Sacco concern, went into liquidation. Stevens has claimed that a man named Pickering bought the right to use Sacco from the liquidator, and that he (Stevens) no longer has any interest in the company of that name. Before leaving the "Sacco" stage of Stevens' multinamed nostrum it is worth recalling that in 1908 an attempt was made to float this humbug in Chicago. Advertisements appeared in Chicago papers describing the alleged enthusiasm for Sacco exhibited by King Edward, Vesta Tilley and Mark Twain! The Chicago venture failed.

THE UMCKALOABO CHEMICAL COMPANY

Not long after Stevens lost his case against the British Medical Association, an item appeared in an Albany, N. Y., paper, regarding the incorporation of the "Umckaloabo Chemical Company" of New York City, capitalized at a quarter-million dollars, for the purpose of acquiring the "secret processes for manufacturing a remedy for tuberculosis and other diseases, discovered by Charles H. Stevens of London." The incorporators of this new company were given as Samuel S. Ryckman, Edward A. Sprong and Irene B. Russell, all of New York City. This was in October, 1914.

In September, 1915, newspaper advertisements appeared, asking for the names of those who were suffering from tuberculosis, so that "an absolute aid in curing tuberculosis" that had been introduced in the United States from London, might be brought to their attention. There was no name signed to the advertisements; neither was the name of the preparation given. Sufferers were urged to write to Room 3240, Woolworth Building, New York City. Some who answered the advertising received a typewritten letter from the Umckaloabo Chemical Co., of 1790 Broadway, New York, which was selling "U. C. Extract." With it was a testimonial, and a typical nostrum "analyst certificate," the latter signed by one J. P. Lord of London. This same "analyst" was referred to at some length at the trial of *Stevens* v. *British Medical Association*. It appears that Lord was an employee of Stevens; he received $7.50 (30 shillings) a week. Although Stevens attempted to "play up" the analysis in the trial, he did not, at the second trial, put the analyst on the stand. The following quotations from the evidence will help one to estimate the possible scientific standing of Analyst Lord. Stevens was being questioned:



TELEPHONES

U. C. EXTRACT

MANUFACTURED BY

UMCKALOABO CHEMICAL CO., INC.

1790 BROADWAY

LABORATORY
1777-1779 BROADWAY

NEW YORK

Greatly reduced facsimile of letterhead used by the Umckaloabo Chemical Company, which attempted to exploit Stevens' nostrum in the United States in 1915. This concern also seems to have fizzled.

Question.—"Is he [J. P. Lord] alive?"

Answer.—"I do not know."

Question.—"Is he not in a Church Army Home and a dipsomaniac?"

Answer.—"I do not know."

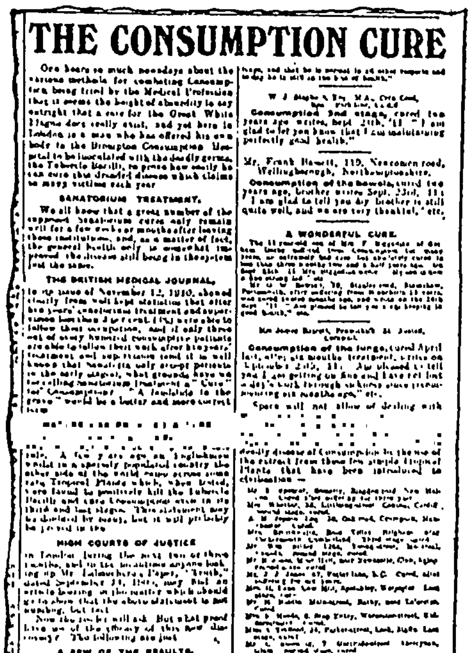
A year later—July, 1916—the same analysis and the same lone testimonial were being sent out, together with a typewritten sheet giving the "History of the Discovery of Umckaloabo." This "history" referred to the "attacks" by London *Truth* and the *British Medical Journal*, and recorded the fact that, in refutation, Stevens had sued the British Medical Association. It failed to record, however, the outcome of the libel suit, leaving the impression that Stevens was the victor. The "history" explained further that the president of the Umckaloabo Company was "Samuel S. Ryckman, former Member of Parliament of the Dominion of Canada," who had secured the American rights to "Stevens' discovery," and that "wonderful results have been accomplished by reputable physicians of New York City, who are convinced that Umckaloabo Extract has produced specific action upon the lungs"!

"SACCO" "LUNGSAVA" BECOME "U. C. EXTRACT"

In transporting this humbug across the Atlantic, still another name has been given to it. No longer is it "Sacco" or "Lungsava"; it is now "Umckaloabo Extract," or, more briefly, "U. C. Extract," the two letters standing, respectively, for "Umckaloabo" and "Chijitse." In addition to the "history," Lord's "analysis," and the one single testimonial for the "cure" itself, there were two testimonals for Mr. Ryckman, one from Adam Brown, postmaster of Hamilton, Ontario, and the other from S. D. Biggar, the mayor of Hamilton, Ontario. The letters accompanying the advertising material were signed "Samuel S. Ryckman"; one of them referred to analyst Lord as "one of the principle analysts of London, England."

Since 1916 we have received no further information regarding the exploitation of "U. C. Extract," or of the activities of the Umckaloabo Co. Whether the business failed to be the financial success that had been looked for, or whether Mr. Ryckman, after further investigation, decided to go into some more reputable line of endeavor, we are unable to say.

Now, in 1919, Stevens plies his abominable trade among the tuberculous victims of the great war. He sends to Canadian soldiers a gaudy covered booklet containing some of the testimony of his "experts" who testified at the *first* trial of his libel suit against the British Medical Association. It leaves the impression that Stevens won the suit. The booklet declares that the British Medical Association charged Stevens "with being a swindler and a quack who foisted upon the public a so-called remedy which he knew to be absolutely worthless." But it does not tell the consumptives, whose dollars are sought, that the court held the British Medical Association's charge to be the truth and a fair comment of fact!



THE CONSUMPTION CURE

THE DISCOVERER'S £1,000 GUARANTEE.

CHAS. H. STEVENS,
204, WORPLE ROAD, WIMBLEDON, S.W.

Photographic facsimile (reduced) of one of Stevens' advertisements, appearing a few years ago in a London paper. The original measured about 11 inches by 5 inches. Among the names listed in this advertisement of those who had been "cured" by Stevens' nostrum was one Miss Olley, of whom Stevens said: "Carried out of Brompton Hospital as incurable, now enjoying good health." The facts are, Miss Olley died of pulmonary tuberculosis.

The ubiquitous "analysis" of Lord—the 30-shillings-a-week "expert"—is also part of Stevens' present advertising paraphernalia. Then there is a loose-leaf booklet of testimonials. The loose-leaf idea seems a good one—commercially. The Journal has shown repeatedly in cases of testimonials for "consumption cures"—testimonials which were written in good faith by those who believed themselves benefited—that where the poor victims really had the disease and were relying on the nostrum it was only necessary to wait some months or a year or two before it was possible to obtain the death certificate of the testimonial givers. In the past this has meant that the quack must "scrap" a lot of "literature" or lay himself open to the charge of publishing testimonials from dead men. The loose-leaf method employed by Stevens will facilitate the elimination of "dead timber" at a minimum expense.

That Stevens, after being thoroughly discredited, first in South Africa and later in England, should now be trying to capitalize the suffering of Canadian soldiers who have contracted tuberculosis in the service of their country, is entirely in keeping with the moral standards of the "consumption cure" quack. The most effective protection of the sick from the wiles of men of the Stevens type is that of giving the public all the facts possible regarding such concerns. Here, briefly summarized, are the facts:

1. In 1904 Stevens was selling "Sacco" in Capetown, South Africa. When clearing $15,000 a year, he got into the courts and found it expedient to leave Capetown.
2. In 1906 Stevens was in Johannesburg, trading as the "South African Institute of Medicine" and selling his stuff as "Lungsava"; was twice convicted of violating the law and left for England.
3. In 1907 Stevens was in London selling his "cure" and in 1910 was declared by the courts to be guilty of "intentional and well considered fraud," and his "cure" denounced as "nothing but quack remedies."
4. In 1908 the British Medical Association denounced Stevens as a quack and declared his nostrum worthless; and when Stevens sued the association the courts, in 1914, agreed that the characterization was justified.
5. In 1915 Stevens' "cure" appeared in the United States under the name of "U. C. Extract," exploited by the Umckaloabo Chemical Company of New York City. This apparently was not a commercial success.
6. Today Stevens is attempting to exploit tuberculous Canadian soldiers who have acquired the disease in the service of their country.

Correspondence

ATYPICAL FORM OF STREPTOCOCCUS VIRIDANS

To the Editor:—In an article on "Prophylactic Inoculation Against Respiratory Infections During the Present Pandemic of Influenza" (The Journal, Jan. 4, 1919, p. 31), Dr. E. C. Rosenow described an atypical form of *Streptococcus viridans,* as it occurred in and about Rochester, Minn. This description corresponds so closely with that of the prevalent type of *Streptococcus viridans,* as it occurred at Camp Shelby, Miss., during the winter and spring of 1918, that I think it worth while to draw attention to it.

My description of the peculiar type of *Streptococcus viridans* at Camp Shelby, Miss., which I had the opportunity of studying only during the latter part of the epidemic (April, May and June, 1918), was presented as part of the report by Major George L. Lathrope, M. C., before the Section on Practice of Medicine at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918 (The Journal, Aug. 10, 1918, p. 451). In the discussion of Major Lathrope's paper I went a little more in detail into the bacteriologic characteristics of this organism, and into the clinical features and mortality of the cases of pneumonia and empyema, caused by an infection with this organism.

As there is no mention of Major Lathrope's report in Dr. Rosenow's paper, it is probable that he has overlooked it. This communication will possibly help to draw his attention to it, so that he will be able to add the additional information to the final report which he evidently intends to make on the prophylactic inoculations against respiratory diseases.

I might add, as a point of interest, that I have recently isolated from the lungs in a case of pneumonia that came to necropsy at Savenay, France, an identical organism which had produced in the patient a fatal pneumonia complicated by an empyema.

One of the important features of the empyemas caused by this peculiar type of *Streptococcus viridans* was the great tendency to the encapsulation of the pus. The pus formed pockets that were difficult to diagnose except by the roentgen ray. The mortality of the empyema cases was also very low, not more than 10 per cent. Both these features indicate the relative attenuation of the virulence of this organism as compared, for instance, with *Streptococcus hemolyticus*.

Abraham Zingher, Capt., M. C., U. S. Army,
Base Laboratory, Base Section No. 5.
A. P. O. 716, A. E. F., Brest, France.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

BOOKS FOR STUDENTS OF SPANISH

To the Editor:—Please recommend a list of books for reviewing and extending one's knowledge of the Spanish language. The following is the type of books I have in mind:

1. Spanish-English grammar and lessons, designed for English speaking students.
2. Spanish lexicon, general.
3. Spanish lexicon, medical.
4. Set of readers, beginning with primer as used in common schools.
5. Osler's textbook of Medicine—Spanish text.
6. Other Spanish medical texts.

V.

Answer.—The number of books for "reviewing and extending one's knowledge of the Spanish language" is practically legion. All have their advantages and their defects, and choice must rest with the individual.

1. Otto-Sauer (Wycil & Co.); Cortina (R. D. Cortina Company); Berlitz; De Tornos (D. Appleton & Co.); Hossfeld (Caspar & Co.); Hall (World Book Company); Rosenthal (International College of Languages); Hugo (Sissmann & Son); Whittem & Andrade (Heath). Certain inexpensive booklets, like "Spanish Self Taught," by F. Thimm, give the phonetic pronunciation and an epitome of the grammar.

2. The standard grammar and dictionary are those of the Royal Spanish Academy (La Real Academia Española) published by Hernando y Compañía in Madrid. There are a number of Spanish-English dictionaries, practically all of which leave much to be desired. Among these are Velázquez' (D. Appleton & Co.); Cuyás' (D. Appleton & Co.); MacDonald's (Pitman); McLaughlin's (David McKay); Nelson's (Thomas Nelson & Sons); Appleton's; Wessely's (David McKay); Casares' (Saturnino Calleja).

3. There is no standard Spanish medical dictionary which can be compared to books of this character in English. Several small dictionaries have been published, mostly adaptations from the French or the German. Among these are Garnier's & Delamare's (Bailly-Baillière); and Galtier-Boissière's (Larousse).

4. Sets of Spanish readers for use in schools have been published by a number of American houses, such as the American Book Company, Ginn & Co., and D. Appleton & Company. The same houses have also published a number of more advanced books for similar use.

5. Osler's textbook of medicine—D. Appleton & Co.—has been translated into Spanish.

6. Most Spanish medical books are translations from the French or the German. In our Spanish Edition appear advertisements of some American books translated into Spanish. Among standard books written by Spanish physicians in use in Spanish schools may be mentioned:

Manual de Medicina Interna—three volumes. Publicado bajo la dirección de los Drs. Teófilo Hernando y Gregorio Marañón. Published by Ruiz Hermanos, Madrid, Spain.

Compendio de Parasitología. By Dr. G. Pittaluga and published by the Librería de la Facultad de Medicina, Calle Atocha, Madrid.

Patología General. By Dr. A. Gimeno (former minister of the interior) which can also be ordered through the foregoing booksellers.

Any reliable bookseller will order the books mentioned above, especially those in the importing business, as Brentano's, Fifth Avenue, New York, and P. B. Hoeber, 67 East Fifty-Ninth Street, New York. They could also be purchased directly from some Havana firm, as Ricardo Veloso, Galiano Num. 62, Havana.

We may add that we are now contemplating the publication of a booklet containing the English and Spanish equivalents of those terms most in use in the daily practice of a physician. Scientific terms derived from Latin and Greek are generally recognizable without a dictionary.

PREPARATION OF SURGICAL SOLUTION OF CHLORINATED SODA (DAKIN'S SOLUTION)

To the Editor:—Please publish the formula of Dakin's solution or the best solution of this kind recommended.

W. A. von Zellen, L'Anse, Mich.

Answer.—According to New and Nonofficial Remedies, 1919, surgical solution of chlorinated soda may be prepared:

1. By the electrolysis of a sodium chlorid solution. This method is applicable only where there is suitable apparatus and electric current.

2. By the action of chlorin on sodium carbonate. This may be done either by the use of a specially devised apparatus to measure the chlorin, or by the use of ampules containing a definite weight of chlorin; such ampules are introduced into a container holding a solution of sodium carbonate of the required strength, and after the container is tightly stoppered the ampule is broken to permit the chlorin to react with the sodium carbonate.

3. By the interaction of chlorinated lime ("bleaching powder") and sodium carbonate solutions with subsequent treatment with either (*a*) boric acid or (*b*) sodium bicarbonate to reduce the alkalinity, as follows:

(*a*) *Dakin's Method.*—A strong solution of hypochlorite is prepared as follows:

Mix thoroughly 150 gm. of chlorinated lime and 500 c.c. of water, and to this mixture add 105 gm. of monohydrated sodium carbonate dissolved in 500 c.c. of water. After standing several hours with frequent shaking, the mixture is filtered and a measured portion (20 c.c.) rapidly titrated with half-normal boric acid solution using *powdered* phenolphthalein as an indicator, in order to determine the amount of boric acid to be added to the remainder of the filtrate (each cubic centimeter of half-normal boric acid indicates 3 gm. of boric acid to be added). It is best to add slightly less than the calculated amount of boric acid. The concentrated solution thus prepared contains about 4 per cent. sodium hypochlorite and may be kept for a month without serious decomposition if protected from light. Before use it should be diluted to its proper strength—usually 1 volume mixed with 7 volumes water—as determined by titration.

(*b*) *War Demonstration Hospital Modification of Daufresne's Method.*—The percentage of available chlorin in the chlorinated lime to be employed is first determined.

To make about 40 liters: Place in a 20 liter container the amount of chlorinated lime indicated in the following table; mix this well with 5 liters of tap water and allow to stand several hours.

"Available" Chlorin in Chlorinated Lime, Per Cent.	Chlorinated Lime for 5 Liters Water, Gm.	Monohydrated Sodium Carbonate in 5 Liters Water, Gm.
20-26	800	700
28-34	600	490
36-42	500	390

Dissolve the designated amount of monohydrated sodium carbonate in another 5 liters of water, and pour the solution into the bottle containing the chlorinated lime; mix thoroughly and allow the calcium carbonate to settle. (If all the calcium is not precipitated, add small amounts of sodium carbonate solution until precipitation is complete.) Siphon off the supernatant liquid through a double filter. This concentrated and alkaline solution will keep for several weeks. For use it is treated as follows: A measured portion (from 20 to 50 c.c.) is titrated with 10 per cent. hydrochloric acid until the red color produced by the addition of solid phenolphthalein disappears (more solid phenolphthalein is added to determine that decolorization was not due to bleaching). The calculated amount of 10 per cent. hydrochloric acid is then added to the original specimen, having a volume designated "V." After the acid has been added, a volume the same as "V" of 6.25 per cent. sodium bicarbonate solution is added. The chlorin content of this concentrated solution is now determined by the method prescribed for the assay of solution of chlorinated soda, U. S. P., and it is then diluted to the proper strength.

This solution should meet the following requirements:

If to 20 c.c. of surgical solution of chlorinated soda about 0.02 gm. of phenolphthalein powder is added, no red color develops on agitation (*absence of excessive alkalinity*).

If to 5 c.c. of the solution contained in a test tube about 0.5 c.c. of 1 per cent. alcoholic solution of phenolphthalein is added ("squirted"), a red color should form and soon disappear (if there is no red flash, the alkalinity is too low).

If the available chlorin of surgical solution of chlorinated soda is determined by the assay method for solution of chlorinated soda, U. S. P., it should contain not less than 0.38 gm. nor more than 0.48 gm. of available chlorin in 100 gm., equivalent to not less than 0.4 gm. nor more than 0.5 gm. of sodium hypochlorite (NaOCl) in 100 gm.

BONUS TO DISCHARGED MEDICAL OFFICERS

To the Editor:—Is a medical officer who was honorably discharged from the service on Jan. 30, 1919, entitled to the bonus of $60 which is now being given to discharged soldiers? If so, to whom is an application for the bonus to be made? Please omit my name.

K. C. D.

Answer.—Yes. According to Section 1406 of the Revenue Act of 1918, all persons serving in the military or naval forces of the United States during the present war who have, since April 6, 1917, resigned or been discharged under honorable conditions (or, in the case of reservists, been placed on inactive duty), or who at any time hereafter (but not later than the termination of the current enlistment or term of service) in the case of the enlisted personnel and female nurses, or within one year after the termination of the present war in the case of officers, may resign or be discharged under honorable conditions (or, in the case of reservists, be placed on inactive duty), shall be paid, in addition to all other amounts due them in pursuance of law, $60 each.

This amount shall not be paid (1) to any person who, though appointed or inducted into the military or naval forces on or prior to Nov. 11, 1918, had not reported for duty at his station on or prior to such a date; or (2) to any person who has already received one month's pay under the provisions of Section 9 of the act entitled "An Act to authorize the President to increase temporarily the military establishment of the United States," approved May 18, 1917; or (3) to any person who is entitled to retired pay; or (4) to the heirs or legal representatives of any person entitled to any payment under this section who has died or may die before receiving such payment. In the case of any person who subsequently to separation from the service as above specified has been appointed or inducted into the military or naval forces of the United States and has been or is again separated from the service as above specified, only one payment of $60 shall be made.

The foregoing amount, in the case of separation from the service prior to the passage of the act, will be paid as soon as practicable; in the case of separation from the service after the passage of the act, payment is made at the time of discharge.

Claims for the bonus should be sent to the Zone Finance Officer, Lemon Building, Washington, D. C. The application for bonus should be accompanied by (*a*) the discharge certificate or a certified copy thereof, (*b*) a statement of all military service since April 6, 1917, and (*c*) the address to which the check should be sent.

PROCAIN ANESTHESIA

To the Editor:—1. Is there any evidence of latent injury to the dental nerves from repeated injections of procain by dentists to control hypersensitiveness of teeth when operating on them? 2. Is it possible that the irritation of from twenty to thirty injections into one section of a nerve within two or three years may produce degenerative changes or start new growth? 3. Is it a safe risk for a 15-year-old patient?

G. W. Fitz, M.D., New York.

Answer.—1. There is no evidence of latent injury to the dental nerves from repeated injections of procain to control supersensitiveness of the teeth. If an isotonic solution is used and this solution made thoroughly sterile by boiling, it is not probable that it will be injurious.

2. It would hardly seem probable that a new growth would be started by the injection of procain into the nerves supplying the teeth.

3. No bad effects need be expected from the cautious use of procain anesthesia for children 15 years of age or younger.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Arkansas: Little Rock, May 13. Sec. Eclectic Bd., Dr. C. E. Laws, 803½ Garrison Ave., Ft. Smith; Sec. Regular Bd., Dr. T. J. Stout, Brinkley.

District of Columbia: Washington, April 9-11. Sec., Dr. Edgar P. Copeland, The Rockingham, Washington.

Florida (H): Jacksonville, April 8. Pres., Dr. Chas. W. Johnson, 33 E. Monroe St., Jacksonville.

National Board of Medical Examiners: Philadelphia, June 2-7. Sec., Dr. J. S. Rodman, 1310 Medical Arts Bldg., Philadelphia.

Nevada: Carson City, May 5. Sec., Dr. S. L. Lee, Carson City.

New Mexico: Sante Fe, April 14-15. Sec., Dr. W. E. Kaser, East Las Vegas.

New York: Albany, Buffalo, New York and Syracuse, May 20-23. Mr. George M. Wiley, director, Exam. and Inspections Div., State Edu. Bldg., Albany.

Oklahoma: Oklahoma City, April 8-9. Sec., Dr. J. J. Williams, Weatherford.

Utah: Salt Lake City, April 7-8. Sec., Dr. G. F. Harding, Templeton Bldg., Salt Lake City.

Special Courses in British and French Universities

A letter from Lieut.-Col. James A. Harvey, Perequeux Hospital Center, France, reports that British and French universities have arranged to enroll American officers and soldiers in special four-month courses in letters, science, law and medicine. The courses were to begin about February 16 and end about June 30. It is estimated that 11,000 soldiers have been enrolled and that the number will reach 20,000. Only men of excellent military character, who have completed, as a minimum, two years of college work or its equivalent, have been enrolled. For those entering the French universities a moderate knowledge of French was required. Officers and soldiers electing the courses have been placed on detail service for the period of study; they receive $2 per day for subsistence and the actual cost for room rent not to exceed $1 a day; traveling expenses are also paid by the government, but the student himself is required to pay the tuition charges which amount to about 250 francs ($48.25). Soldiers retain their full equipment without arms or ammunition. In France medical courses are being given at Toulouse, Paris and Lyons; and in the English universities at London and Liverpool.

Minnesota January Examination

Dr. T. S. McDavitt, secretary of the Minnesota State Board of Medical Examiners, reports the oral, practical and written examination held at Minneapolis, Jan. 7-9, 1919. The examination covered 15 subjects and included 80 questions. An average of 75 per cent. was required to pass. Five candidates were examined, all of whom passed. Three candidates were licensed through reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Rush Medical College		(1918)	78
University of Illinois		(1919)	86
Harvard University		(1917)	92
Tufts College Medical School		(1911)	79
Syracuse University		(1909)	83

College	LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
Northwestern University		(1918)	Illinois
Western Pennsylvania Medical College		(1904)	Penna.
University of Toronto		(1905)	Illinois

South Dakota January Examination

Dr. Park B. Jenkins, secretary of the South Dakota State Board of Health and Medical Examiners, reports the practical and written examination held at Pierre, Jan. 14-16, 1919. The examination covered 15 subjects and included 110 questions. An average of 75 per cent. was required to pass. Of the 4 candidates examined, 3 passed and 1 failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Chicago College of Medicine and Surgery		(1911)	92.7
Indiana Medical College (Purdue Univ.)		(1907)	92
Eclectic Medical Institute		(1877)	77.3
	FAILED		
Northwestern University		(1908)	67.1

Book Notices

Les Borgnes de la Guerre: Prothèse Chirurgicale & Plastique (Valois et Rouveix). Par le Dr. G. Valois, Membre de la Société d'Ophtalmologie de Paris. Paper. Price, 12 francs. Pp. 228, with illustrations. Paris: Masson & Cie, 1918.

This treatise is essentially a contribution—and a most valuable one—to military ophthalmology, especially as regards the physical reconstruction of visual organs, damaged or destroyed by engines of war. The author confines his remarks to a consideration of the borgne, or "one-eyed" victim of battle. It is a matter of regret that we have no one word in English exactly corresponding to this term. As the advertisement points out, the experienced surgeon, during times of peace, was generally able to meet the requirements of most bulbar and orbital injuries and diseases calling for removal of the eyeball. He got along with some simple form of enucleation or its substitutes, modified to suit special cases, such as exenteration, amputation of the anterior segment of the eye, etc. Now and then, but still rarely, he was called on to do a plastic operation on the lids, to restore a lost conjunctival sac, or to deal with a contracted and cicatricial socket so that the patient might wear an artificial eye.

The advent of war and the appearance of large numbers of war-wounded patients with severe orbitofacial injuries changed all this; the ophthalmic surgeon was no longer able to confine his technic to a few old and familiar methods. It seemed as if each case called for special treatment, involving some decided modification of an old or the adoption of an entirely new plan of surgical procedure. To this demand for new and more elaborate operative measures the military situation added other difficulties—insufficient stocks of prostheses (sometimes an entire lack of artificial eyes), dearth of special workmen, and so on. One of the results of these conditions was to bring about in France (as in some other countries) a coordination of the various factors in the usual supply of material—surgical and artistic—for the benefit of those soldiers whose wounds required them. In addition to these precautions, the medicomilitary authorities of the Thirteenth Region created a studio for the study of the subject and for the manufacture of ocular and orbital masks and other prostheses for the improvement of the cosmetic appearance of those unfortunates with extensive orbital injuries. The output of this studio is pictured in both the text and plates of the volume.

The name of Dr. Valois is familiar to ophthalmic surgeons, and he has freely given us not only his own wide experience, but also that of other well-known operators. The book abounds in descriptions and illustrations of the many methods employed to relieve the great variety of injuries involving the tissues of the face, lids and orbital walls. Especially does the author discuss the numerous plastic operations now in vogue, and he describes the steps of these operations in detail. In fact, the monograph may be regarded as an oculoprosthetic textbook with special chapters on orbital masks, molds and other cosmetic contrivances. The one criticism one might make is of the illustrations—both the colored plates and the black and white cuts in the text are very poor, and are entirely unworthy of this otherwise admirable treatise. However, many of them are useful as diagrams, and since diagrammatic illustration in a work of this sort is of prime importance, one may accept them as meeting the chief demand.

The Surgery of Oral Diseases and Malformations: Their Diagnosis and Treatment. By George Van Ingen Brown, D.D.S., M.D., C.M., Major, Medical Officers' Reserve Corps, U. S. Army. Third edition. Cloth. Price, $7. Pp. 734, with 570 engravings. Philadelphia: Lea & Febiger, 1918.

This edition, with the exception of a chapter that has been added on war surgery, does not differ materially from the edition immediately preceding. In connection with the chapter on war surgery there are a number of illustrations showing the results of gunshot wounds of the face and jaws, together with methods for plastic and other restorations, methods of splinting of fractured jaws, and bone grafting. The illustrations in this chapter and the description of cases are for the most part drawn from the results of the experiences of a number of different surgeons who were actually engaged in reconstruction work, in the hospitals of France. The book is comprehensive, covering most of the diseases, injuries and malformations found about the face, mouth and jaws.

Social Medicine, Medical Economics and Miscellany

Program of the Public Health Service, Intended Especially to Meet After-the-War Needs

This program meets urgent national needs by outlining health activities which are practicable and which will yield the maximum result in protecting national health and diminish the annual toll of thousands of lives taken by preventable diseases and insanitary conditions. The success of this program will depend on the active cooperation of federal, state and local health authorities. Experience has shown that this cooperation can best be secured on the federal aid extension principle.

1. Industrial hygiene:

(*a*) Continuing and extending health surveys in industry with a view to determining precisely the nature of the health hazards and the measures needed to correct them.

(*b*) Securing adequate reports of the prevalence of disease among employees and the sanitary conditions in industrial establishments and communities.

(*c*) National development of adequate systems of medical and surgical supervision of employees in places of employment.

(*d*) Establishment by the Public Health Service, in cooperation with the Department of Labor, of minimum standards of industrial hygiene and the prevention of occupational diseases.

(*e*) Improvement of the sanitation of industrial communities by officers of the Public Health Service, cooperation with state and local health authorities, and other agencies.

(*f*) Medical and sanitary supervision by the Public Health Service of civil industrial establishments owned or operated by the federal government.

2. Rural hygiene:

(*a*) Federal aid extension for establishment and maintenance of adequate county health organizations in counties in which the county and state governments, separately or together, will bear at least one half (usually two thirds) of the expense for reasonably intensive rural health work; county health officer to be given status in national health organization by appointment as field agent of the Public Health Service at nominal salary; sanitary inspectors and health nurses also to be given official status in the Public Health Service.

(*b*) Detail of specially trained officers of the Public Health Service to formulate and carry out, in cooperation with local authorities, intensive campaigns for the sanitation of groups of rural towns, the work to be directed especially toward securing safe water supplies, cleanly disposal of human excreta, pasteurization of milk supplies, and bedside control of cases of communicable disease.

(*c*) Studies by a special board of service officers to determine improved methods of rural sanitation, the studies to be confined to the most practical and essential phases of the subject.

(*d*) Widespread dissemination of the simple rules for rural sanitation through various governmental and civil agencies, such as the bureaus and divisions of the Department of Agriculture, the Farm Loan Board, agricultural colleges, public-school boards, farmers' associations, and women's clubs.

3. Prevention of the diseases of infancy and childhood:

(*a*) Through cooperation with the Children's Bureau, the American Red Cross, and other recognized agencies in promoting measures for child and maternal welfare.

(*b*) Through prenatal care by promoting:

(1) The adoption of measures for the adequate care and instruction of expectant mothers through visiting nurses, prenatal clinics, lying-in facilities, attention during confinement, and regulation of the practice of midwifery under medical supervision.

(2) Safeguarding of expectant mothers engaged in industries.

(*c*) Through infant-welfare work, by promoting:

(1) The accurate registration of all births and measures for adequate care of babies in homes, welfare stations, and day nurseries.

(2) Instruction of mothers by visiting nurses. The enforcement of prophylactic measures to prevent blindness in the new-born.

(3) Safeguarding of milk supplies and establishment of pasteurization plants.

(*d*) Through supervision of children of preschool age, by promoting:

(1) The organization of divisions of child hygiene in state and local health departments.

(2) Instruction by visiting nurses in general, personal, and home hygiene, and inspection for physical defects and the control of communicable diseases.

(3) The establishment of clinics for sick children.

(*e*) Through supervision of children attending school, by promoting:

(1) The supervision of the home and school environment, including sanitation of school grounds and school buildings.

(2) The maintenance of health supervision of school children by school nurses and school physicians to detect and correct physical and mental defects and to control communicable diseases.

(3) Mental examinations of schoolchildren to determine and prescribe suitable treatment and training for children who fail in class work.

4. Water supplies. National development of safe water supplies:

(*a*) By extending surveys already made by the Public Health Service of water supplies, checked by laboratory analyses when necessary, to be done by national, state, local, or university personnel and laboratories.

(*b*) Introduction and extension of methods of water purification according to results of surveys and analyses.

(*c*) Stimulation of communities to obtain safe water through national, state and local representatives and volunteer organizations.

5. Milk supplies. National development of safe milk supplies through:

(*a*) Universal pasteurization (including adequate municipal supervision).

(*b*) Adequate inspection of production and distribution of milk and milk products.

(*c*) Stimulation of communities to obtain safe milk through national, state and local representatives and volunteer organizations.

6. Sewage disposal. Proper sewage disposal will control intestinal diseases, such as typhoid fever, dysentery, diarrhea and hookworm. These diseases now cause over 60,000 deaths annually. National development of safe methods through:

(*a*) Extension of water carriage sewerage systems wherever practicable.

(*b*) Elimination within municipal limits of cesspools and privies.

(*c*) In rural communities the installation of sanitary privies.

(*d*) The establishment of minimum standards of permissible pollution of streams, lakes and rivers used for water supplies.

(*e*) Stimulation of communities to obtain safe sewage disposal through national, state and local representatives and volunteer organizations.

7. Malaria. National development of measures for the control of malaria and malaria-bearing mosquitoes in industrially, agriculturally and economically important areas of the United States:

(*a*) By the further dissemination of the knowledge of methods for its control (elimination of malaria-mosquito breeding places through drainage, oiling, ditching, and the like) now being demonstrated by the Public Health Service.

(*b*) By the extension throughout the country of surveys of certain areas as to the prevalence of malaria and malaria-bearing mosquitoes.

(*c*) By increasing the corps of experts of the Public Health Service engaged in malaria prevention and by the utilization of other national agencies wherever practicable to advise the communities as to the methods for best handling their problems in malaria.

(*d*) Additional appropriations for the reclamation of large areas from malaria through proper drainage. Funds for such projects should be supplied on a 50-50 basis by federal and state governments. This plan is especially applicable to the control of malaria in communities where malaria conditions interfere with their economic development.

8. Venereal diseases:

(*a*) Medical measures:

(1) Establishment of clinics, dispensaries and hospitals.

(2) Epidemiologic studies.

(3) Free diagnosis.

(4) Examination for release as noninfective.

(5) Free distribution of arsphenamin.

(6) Control of carriers through detention and commitment.

(*b*) Educational measures:

(1) Proper reporting of cases.

(2) Standardization of pamphlets, exhibits, placards and lectures.

(3) Cooperation with national, state and local authorities, and volunteer associations.

(4) Cooperative work in industrial plants, shipyards and railway employees' organizations.

(5) Cooperation with druggists' organizations to secure their voluntary aid in the control of patent nostrums for the treatment of venereal diseases.

9. Tuberculosis:

(*a*) Stringent provisions for the proper reporting of cases of tuberculosis.

(*b*) Adequate instruction of families and patients, especially in families where there is an advanced case.

(*c*) Hospitalization of cases wherever practicable, either through city institutions or by arrangements with state or district tuberculosis hospitals.

(*d*) Cooperation with national societies and agencies having for their object the prevention of tuberculosis or the improvement of economic conditions.

(*e*) Improvement of industrial conditions predisposing to tuberculosis, such as "dusty occupations."

10. Railway sanitation:

(*a*) Consolidation under supervision of the Public Health Service of railway sanitation.

(*b*) Protection of railway employees by adequate health measures (e. g., protection against smallpox and typhoid fever by vaccination and inoculation; supervision of food, water and milk supplies consumed by employees; elimination of health hazards in shops and other work places; supervision of sanitary housing facilities; sanitation of railway communities).

(*c*) Protection of the public by:

(1) Sanitary supervision of water, milk and food supplies furnished by railway administration.

(2) Sanitary supervision of employees engaged in handling water and food supplies so furnished.

(3) Sanitation of stations, terminals, rights of way, with special reference to sewage disposal, malaria-mosquito eradication, and screening against insect-bearing disease.

(4) Prevention of the spread of communicable diseases through common carriers.

(5) Improvement and regulation of ventilation of passenger coaches and railway tunnels.

11. Municipal sanitation:

(*a*) Development and demonstration of the principle of employing full-time health officers by all municipalities.

(*b*) Enactment and enforcement of ordinances for adequate disease reporting.

(*c*) Provision for safe water, food and milk supplies and sewage disposal.

(*d*) Enactment and enforcement of special regulations for the improvement of conditions causing tuberculosis.

(*e*) Establishment of community health centers.

(*f*) Municipal campaign for the control of venereal diseases through venereal-disease reporting; clinics for the treatment and control of carriers, and free treatment for all cases.

(*g*) Control of malaria and malaria-bearing mosquitoes in malarious regions.

(*h*) Enactment of proper building ordinances and provision for sanitary supervision of housing, especially in industrial centers, including improvements in transportation, so as to permit redistribution of persons living in overcrowded communities.

(*i*) Adequate systems of medical supervision of schools.

(*j*) Reduction of infant mortality by proper organization for prenatal care, bed space in maternity hospitals, and infant-welfare stations, visiting nurses, and milk and ice stations.

(*k*) Stimulation of municipalities to realize their own responsibilities for health, and the part played by adequate health protection in the happiness and material prosperity of the community.

12. Health standards:

(*a*) Communicable diseases. Promulgation by the Public Health Service of minimum standards for the control of communicable diseases.

Note.—The service has published on this subject a report of committee of the American Public Health Association, on which the service was represented. This report should be reviewed and amended by a board of service officers. It should then be formally approved by the conference of state and territorial health officers with the Public Health Service, and be promulgated by the Public Health Service as federal standards.

(*b*) Industrial hygiene. Standards of industrial hygiene and sanitation of places of employment should be prepared by the service in cooperation with the Department of Labor.

(*c*) Sewage and excreta disposal. Minimum standards should be promulgated on the following:

(1) Water-carriage sewerage systems.

(2) Sanitary privies.

(*d*) Standard specifications for safe water and water purification.

(*e*) Community sanitation. Preparation of standard methods for scoring the sanitary condition of communities.

(*f*) Preparation of additional standards for the manufacture and the purity and potency of biologic products and for arsphenamin.

(*g*) Preparation of standards for illuminating, heating and ventilating public buildings and schools.

13. Health education. To increase the knowledge of the general public on means relating to disease prevention and personal hygiene:

(*a*) By the employment of medical sanitarians, having special experience in educational methods and their use, in cooperation with Red Cross national and state organizations, state and municipal health departments, state industrial commissions, and state and national health associations.

Note.—The prevention of the following conditions and diseases will be the special objects of health education: excessive infant mortality, occupational diseases (see section on industrial hygiene), malaria, typhoid fever, hookworm, venereal diseases, pellagra, tuberculosis, pneumonia, cerebrospinal meningitis, and personal hygiene.

(*b*) By advocating and assisting in the securing of full-time state, district and local health officers.

(*c*) By stimulation of states and municipalities to the acceptance of their full responsibility for public health conditions and the support of health activities by adequate appropriations.

(*d*) By the detail of service officers to state health organizations and, when necessary, to city organizations, particularly in communities presenting special health problems.

14. Collection of morbidity reports. Extension of disease reporting to be accomplished through the collection of adequate reports of disease prevalence:

(*a*) By the extension of the present system of collaborating epidemiologists.

(*b*) For the industrial group of the population, through the appointment of industrial surgeons and record clerks in various industrial establishments, such industrial surgeons to be appointed by the Public Health Service, at a nominal salary, so as to place them under the direction and control of the service, and the remainder of the salary to be paid by the industrial establishments to which they are attached. In addition to reporting disease, these surgeons will act as medical and surgical officers and sanitarians. They will also report on community sanitation.

15. Organization and training for duty in emergency of the Reserve of the Public Health Service:

(*a*) By the establishment of training schools in public health work in connection with stations of the Public Health Service and leading universities at which members of the reserve may receive intensive training for short periods at stated intervals.

(*b*) Ordering members of the reserve to active duty to participate in important field work of the Public Health Service.

In order to carry this program into effect the following additional personnel of the Public Health Service is needed:

Industrial hygiene	120
Rural hygiene	200
Prevention of diseases of infancy and childhood	100
Interstate water supplies	20
Milk supplies	15
Malaria:	
Sanitary engineers	20
Epidemiologists	10
Venereal diseases:	
Control in states	88
Control in clinics	240
Tuberculosis investigations	20
Health education	10
Total	843

Evidence of Illegally Prescribing Liquor

(State v. Raub (Wash.), 173 Pac. R. 1094)

The Supreme Court of Washington, in affirming a conviction of the defendant of having prescribed intoxicating liquor without good reason to believe that the patient was actually sick or that the intoxicant was required for medicine, says that the trial judge permitted the introduction of testimony showing the giving of some fifty-six prescriptions other than those given to the party named in the information, and at about the same time. The defendant had issued to his patient five prescriptions between Aug. 26, 1917, and Sept. 11, 1917, each calling for one quart of whisky. On each prescription the patient was directed to take one ounce of the remedy in water three times a day. As these prescriptions obviously called for a greater quantity of liquor than was necessary to meet the needs of the patient if "taken as directed," the good faith of the physician, the issue in this class of cases, was clearly tendered by the state, and to further sustain the issue the other prescriptions were offered. The rule is that, in cases of this character, such evidence is competent.

It was urged that this procedure was violative of the rule that proof of crimes independent and in no way related to the crime charged cannot be established to prove a specific offense. It would be so if the crime charged rested alone in the doing of the act charged. But the gravamen or material part of the offense is not in the doing of the deed, but in the faith in which it was done. The rule seems to have grown out of the necessities of the statute, for the act itself is presumptively a lawful act sanctioned by statute. It is rendered unlawful when, and only when, the writer of the prescription abuses the confidence that is reposed in him and by the injection of bad faith thwarts the police power of the state. From the nature of things, good or bad faith can be proved only by resort to circumstances and side lights. If it were otherwise—if the mere giving of a prescription or a number of prescriptions by a licensed physician would bar further inquiry—the law would be emasculated of its purpose. It is not going beyond the range of judicial vision to say that liquor has not always been regarded as a cure-all or touchstone of health, but that it has grown in popular favor as a remedy as the chance of procuring it has grown remote;

and, although a physician who prescribes it may be imposed on at times, a general dispensation of the remedy at or about the time charged is sufficient to put him to the defense of his good intention before a jury of his countrymen.

It was complained that no testimony was offered to show the physical condition of the patient, or that she did not in fact need the remedy; the charge being that the defendant prescribed liquor "without good reason to believe that she was at the time actually sick or that said intoxicant was required for medicine." But the court thinks the showing that the defendant had theretofore prescribed 4 quarts of liquor, which would have met the "directions" for a time far beyond the time when the prescription on which the charge was made (September 11) was written, was a sufficient circumstance to go to the jury, and, being unmet in any way, was enough to sustain the verdict.

Duty of Physicians Riding Together in Automobile

(Hurt v. Yazoo & M. V. R. Co.; Lewis v. Same (Tenn.), 205 S. W. R. 437)

The Supreme Court of Tennessee had here two actions which were tried together. One was by Hurt, as administrator, to recover damages for the death of a Dr. Nelson. The other was by a Dr. Lewis to recover damages for personal injuries to himself and for the destruction of an automobile. Dr. Lewis and Dr. Nelson were partners in the practice of medicine. Dr. Nelson had a patient a short distance out of the city, and he and Dr. Lewis visited the patient for the purpose of performing a surgical operation. Dr. Nelson performed the operation, but Dr. Lewis assisted him, and carried him to the patient's residence in his own automobile as a guest and without charge. As they were returning from the operation and Dr. Lewis was giving particular attention to the automobile because the road at a "blind crossing" of the defendant's tracks was in bad repair, both at about the same instant saw a train approaching, and, on account of their closeness to the track, Dr. Lewis deeming it best to try to rush across it, the engine struck the automobile about the rear wheel. The trial judge submitted the cases to a jury, which returned a verdict for $30,000 for Hurt, administrator; and for $2,000 for Dr. Lewis; but the judge afterward directed a verdict for the defendant in each case, stating that he was not satisfied that the plaintiffs were entitled to recover under the law, or that they had sustained their cases by a preponderance of the proof.

The supreme court, in reversing the cases, and remanding them for trial, says it does not think that the defendant's contention was well made that Drs. Lewis and Nelson were guilty of such contributory negligence as would bar their right of recovery as a matter of law. Again, the court says that the two physicians were jointly interested in the success of the operation, and in that sense were on a joint enterprise. The interest they had in the journey would doubtless continue until they had returned to their offices, or until they had declared the journey at an end by act or word. The question of imputable negligence did not really arise in the case. The proof showed that Dr. Nelson saw the train at the same instant Dr. Lewis saw it, and gave the alarm. His negligence, if any, was as great as or greater than that of Dr. Lewis, and therefore there was no basis for the contention that Dr. Lewis' negligence was imputable to Dr. Nelson.

The court thinks Dr. Nelson was under the duty of exercising due care for his own safety, notwithstanding Dr. Lewis was driving the automobile. This would be true whether he was a guest of Dr. Lewis, or whether they were engaged on a joint enterprise in which they were both interested. Dr. Lewis was not a common carrier, and was in the exercise of a friendly act in which he had an interest in transporting Dr. Nelson in his automobile. The guest is under the same duty to look out for his own safety as he would be if traveling alone. He cannot close his eyes to obvious danger and rely exclusively on the driver of the automobile to protect him. It is a question of ordinary care and proximate cause. The facts that the plaintiffs were riding in an automobile, and that Dr. Lewis was the guest of Dr. Nelson, could not change their duty to exercise due care for their own safety. This duty was personal to each one.

Care Required of Hospital Conducted for Profit

(Tulsa Hospital Association v. Juby (Okla.), 175 Pac. R. 519)

The Supreme Court of Oklahoma, in affirming a judgment for damages against the defendant association, holds that a hospital that is conducted for private gain receives patients under an implied obligation that it will exercise ordinary care and attention for their safety, and such degree of care and attention should be in proportion to the physical and mental ailments of the patient; and the question whether or not such requirements have been met presents an issue of fact to be determined by the jury. In this case the plaintiff, who had been taken to the defendant's hospital for the purpose of being operated on for appendicitis, maintained that a subsequent attack of pneumonia was due to the bedding on her bed and to her nightgown being wet by a leaking roof, and, for two hours, only the blankets being changed. The court says that it is unable to agree with the contention that there was not shown that degree of negligence on the part of the defendant in permitting water to leak through its roof as would entitle the plaintiff to recover damages for injury sustained thereby. The plaintiff was received into the hospital with an implied understanding and agreement that she would be furnished with a suitable room for a person in her condition. It was incumbent on the defendant to exercise ordinary care in furnishing the plaintiff a suitable and safe place, and to use ordinary care in furnishing the plaintiff a competent nurse, and to use ordinary care in looking after and caring for the plaintiff while she was in its care and custody. These questions presented an issue of fact which was rightly submitted to the jury for determination. From a careful reading of the record the court is convinced that, if the verdict had been based solely on the negligence of the defendant in permitting the plaintiff to remain in her bed for a period of two hours after ascertaining that the roof was leaking and the bed was wet, a verdict on that issue alone would be warranted by the evidence. Furthermore, it appeared that when the plaintiff was placed in the care and custody of the defendant, and was paying the ordinary prices charged by such institution, the defendant did not place a skilled and trained nurse over the plaintiff, but, on the contrary, placed a pupil nurse in the institution, whose training did not cover more than a period of six months, in charge of her, and if the evidence of the plaintiff was to be believed, this pupil nurse permitted her to lie on this wet bed for a period of more than two hours before any effort was made to change her clothes or the sheets on the bed. If this state of facts be true, this conduct alone would constitute such negligence that a cause of action might be predicated thereon, and a judgment recovered. A rehearing was denied.

- *Nervous Symptoms in Pernicious Anemia. H. W. Woltmann, Rochester, Minn.—p. 400.
- Sensitization and Treatment of Bronchial Asthmatics with Pollens. I. C: Walker, Boston.—p. 409.

Cutaneous Aspects of Tuberculosis.—The material used in Stokes' study consisted of thirty cases of the so-called papulonecrotic tuberculid of erythema induratum, and of associated conditions constituting, according to the most widely accepted explanation, the allergic response of a hypersensitized skin to emboli of tubercle bacilli from a tuberculous focus elsewhere in the body. Association with tuberculosis in this series was evidenced by a family history in one fourth of the cases, incontestible objective signs in more than half (57 per cent.), and presumptive signs of the disease in 70 per cent. One third of the patients had roentgenographic signs of pulmonary tuberculosis; an equal number had suggestive or positive physical signs of lung involvement. The importance of lymphatic involvement is illustrated by the fact that two-thirds of them had a tuberculous lymphadenitis.

The type and location of the focus of tuberculosis do not seem to influence the tuberculid beyond the marked association with glandular involvement. On the other hand, the influence of vascular abnormalities and chronic passive congestion in the extremities is very apparent. Ninety-six per cent. of the lesions involved the extremities. Lesions appeared in the ear in 13 per cent. Slight fever at onset, loss of weight in 40 per cent., amenorrhea in 43 per cent. of the women, moderate leukopenia, slight but occasionally severe anemia, and vernal periodicity are the significant signs. An onset and course marked by rheumatic symptoms is very common (46 per cent.) and often misinterpreted. The recognition of the focus of tuberculosis must depend largely on objective evidence. There is a notable absence of cough, sweats and hemoptysis. Florid, seemingly robust types of patients are not infrequently subjects of tuberculids.

Evidence of the importance of a septic focus and collateral types of infections appears from the history of tonsillitis in 39 per cent., "rheumatism" in 46 per cent., pneumonia in 26 per cent., grip in 54 per cent., and pleurisy in 18 per cent. These conditions seemed frequently to stand in direct predisposing or exciting relation to the tuberculid. A total of 70 per cent. had symptoms and findings suggesting the presence of a septic focus, and 62 per cent. had had significant respiratory infections excluding pleurisy. While no direct relation of the tuberculid to the clinical condition of the tonsils could be established, 50 per cent. of the patients had markedly septic tonsils, the remainder were passable and none were normal. Examination of the teeth by roentgen ray in a limited number of the latter cases demonstrated the presence of septic foci in 45 per cent. of nine patients. Removal of the tonsils in seven cases failed to prevent the outbreak of a tuberculid or modify its course, and complete extirpation of all recognizable septic foci in two cases, without removing or treating the tuberculous focus, was also unavailing.

Treatment of Bichlorid of Mercury Poisoning.—The treatment advocated by Rosenbloom is as follows: Administer the whites of three eggs beaten up in a quart of milk and then empty the stomach by siphonage. Give 300 c.c. of fresh calcium sulphid solution, containing 1 grain to 1 ounce of water by mouth. Wash out the stomach with fresh calcium sulphid solution, 1 grain to 1 ounce of water. Administer in powder or tablet 0.36 gm. of sodium phosphite and 0.24 gm. of sodium acetate. If this is not available give the following: Sodium hypophosphite, 1 gm.; water, 10 mils; hydrogen peroxid, 5 mils. Use ten times as much of the hypophosphite as poison taken. Give a copious lavage of the stomach with the above antidote diluted twenty times. Give the above undiluted antidote every eight hours for two days. Pour through the stomach tube after the above lavage a solution of 3 ounces of sodium sulphate and 6 ounces of water containing 5 grains of calcium sulphid. Let these solutions remain in the stomach. Give intravenously after withdrawing 600 c.c. of blood, 800 c.c. of Fisher's solution or bicarbonate-glucose solution. Wash out the stomach morning and night, giving by the mouth after each washing, 5 grains of calcium sulphid dissolved in 3 ounces of water. Continue this lavage until the stomach washings are free from mercury when tested by Elliott's method and until the urine is free from mercury. Give high colon irrigations of warm water morning and night, using 8 gallons of water for each treatment. Give a hot pack twice daily. Give 8 ounces of milk every second hour. Give every second hour 8 ounces of the following solution, by mouth, alternating with the milk: Potassium bitartrate, sodium citrate and sucrose, each 1 dram; lactose, 4 drams; lemon juice, 1 ounce, and boiled water, 16 ounces. Force the patient to drink large quantities of alkaline waters. Give a low fat and low protein and high carbohydrate diet for four weeks. Avoid salt food, as it increases the absorption of the mercury. Give by continuous proctoclysis a solution containing 1 dram potassium acetate, 4 drams glucose and 3 drams sodium bicarbonate to the pint. Keep the urine alkaline. Continue treatment until recovery, usually a period of three weeks.

Migraine.—Rupert and Wilson found on examination that each person having frequent attacks of migraine shows some abnormality of the stool, usually putrefaction, with an alternation of blood-pressure, and these are usually accompanied by delay of kidney function with some disturbance of nitrogen output. Further, this variation of blood-pressure between attacks corresponds with the findings in the stool. For instance, a persistently low blood-pressure reading is apt to be associated with an excessively putrefactive movement, and as the stool condition is corrected, the attacks are less in frequency and in severity, and some cases show improvement in pressure between attacks. The authors are searching for toxin in the putrefactive stool.

Nervous Symptoms in Pernicious Anemia.—Of the 150 patients examined by Woltmann, no less than 80.6 per cent. presented indisputable evidence of the destruction of nervous parenchyma. Approximately 12.7 per cent. of the patients came for the express purpose of seeking relief from symptoms directly attributable to involvement of the nervous system. Chief among these were the paresthesias, especially numbness and tingling of the hands and feet, which were present in about 80 per cent. of all cases, regardless of whether or not involvement of the nervous system could be demonstrated objectively. Occasionally a patient complains of a girdle pain (2.8 per cent.), or the sensation of a tight band drawn around the knees (1.7 per cent.). A number presented themselves for examination because of inability to control the arms and legs properly. In the motor field, cramping of the calves occasionally proved to be the source of great discomfort.

In relation to the cranial nerves, dimunition in the sense of smell, taste and hearing was noted. In 1.4 per cent. of the cases the appearance of nervous symptoms antedated the onset of the anemia, the symptoms that preceded being usually the paresthesias. The duration of the anemia also showed no definite relationship to the time of onset in the nervous symptoms, though in the cases examined the mean duration of the anemia was 2.2 years and the mean onset of the nervous symptoms ten and a half months later. The type of lesion *par excellence* of the nervous system, as evidenced clinically, is a subacute combined degeneration of the cord, regardless of whether this begins in the posterior or the lateral columns or in both simultaneously, though the columns of Gall and Burdock are in the majority of cases first and most extensively involved. Multiple neuritis could be demonstrated in addition to the spinal cord lesion in 4.9 per cent. of the cases.

Standardization of Antipneumococcus and Antimeningococcus Serums.—The results of tests made on antimeningococcus serums produced by different laboratories, and the experience in formulating standard methods for the state are recorded by Wadsworth and his associates as the outcome of this work. Rules and regulations for the testing of the potency of antimeningococcus serum were drawn up. They bear on (1) the type of serum, (2) minimum standard of potency, (3) standard cultures, (4) standard suspensions, (5) method of testing the potency of the serum, (6) physical properties, (7) sterility tests, and (8) expiration date.

Clinical Study of Meningitis.—The important diagnostic features presented by a series of 191 patients with meningococcic meningitis and twenty-four patients with meningitis due to other organisms are analyzed by Stone and Truitt. In 191 cases the mortality was 28.8 per cent. Mixed infection occurred in thirteen instances with a mortality of 92.3 per cent. Meningitis due to other infection than meningococcus occurred in eleven instances with a mortality of 81.8 per cent. Ten out of 191 patients with meningococcus, or 5 per cent., gave a history of an earlier carrier state. Of these ten patients, eight recovered and two died. A definite history of earlier meningitis was given by two patients, one of whom recovered while the other resulted fatally.

Lumbar puncture was performed for diagnostic purposes as early as possible on all meningitis suspects. The usual amount of serum given intraspinally was from 30 to 35 c.c. twice daily during the first five or six days until the reports received from the laboratory showed two or more negative examinations. The average number of intraspinal treatments in 136 recovered patients was eleven; the average total amount of serum received by each was 305 c.c.; the average total drainage of spinal fluid was 571 c.c.

Combined intravenous and intraspinal therapy was resorted to in thirty-two patients. The mortality was 28.1 per cent. Three of the patients died within sixty hours after admission. In one of the fatal cases the patient received 730 c.c. of serum intravenously in eighteen injections, and 460 c.c. of serum intraspinally in twenty injections; in two other fatal cases the patients received 200 and 360 c.c., respectively, by vein and 1,080 and 1,015 c.c., respectively into the spinal canal. The mortality in this series of patients was almost identical with the mortality among 159 patients with meningococcic meningitis treated intraspinally (deaths, forty-six; mortality, 28.9 per cent.).

The point is made by the authors that in a patient still manifesting evidences of the disease, such as positive organisms or fever, in whom mechanically it becomes difficult to continue treatment by spine, the attempt should be made to give serum by vein. If patients have been given a number of intraspinal treatments and subsequently an intravenous injection is contemplated, extreme care in its administration is necessary to avoid serious symptoms of anaphylaxis. It has always proved wise to desensitize before giving the first intravenous injection, by a subcutaneous injection of 1 c.c. of serum. The intravenous injection should be given slowly, at the rate of 1 c.c. of warmed serum per minute for the first 10 or 15 c.c. . If anaphylactic symptoms occur the injection should be stopped and the attempt repeated later. Epinephrin chlorid, 1 c.c. of the 1:1,000 solution, by hypodermic injection, relieves the symptoms of anaphylaxis. Atropin, 1/100 grain, by hypodermic injection is also useful. The serum if mixed, not shaken, with an equal volume of salt solution is less apt to clog the needle.

Plasmaphaeresis in Treatment of Nephritis and Uremia.—Bleeding, removing the plasma and returning the corpuscles after washing with Locke's solution is designated "plasmaphaeresis." In the course of experiments designed by O'Hare and others to disclose the toxic elements in citrated blood transfusions it became expedient to obtain data on removal and return of corpuscles from the same individual. In consequence of this need, the ordinary venesections in uremia patients, which would have been carried through without return of corpuscles, were made instances of plasmaphaeresis, and data were obtained on the possible beneficial effects of this measure. The blood was drawn into sodium citrate, centrifugalized and prepared for return; in no case was sodium citrate added before reinjection, nor was Ringer's solution employed. Seven or eight hundred c.c. of blood were withdrawn, centrifugalized, washed twice with freshly made, sterile, 0.85 per cent. sodium chlorid solution, and the corpuscles were returned made up to the original volume with salt solution. On completing this return, and without inserting another needle, 700 or 800 c.c. of blood were again withdrawn. The corpuscles thus removed were washed twice and reinjected. The patient never experienced a hemorrhage of more than 800 c.c., and he was subjected to no operation except venipuncture, as it should never be necessary to cut down on a vein in such cases.

So far as this procedure was carried out in the one case reported it did not arrest the march of uremia in any degree. The encouraging betterment noted early in the patient's stay in the hospital was no more than is often seen from rest and proper diet. Other patients on whom the maneuver was used have been of similar type and have received no benefit from it or from blood transfusion. Plasmaphaeresis was carried out eighteen times in eight different cases of chronic nephritis and uremia without definite benefit to the patients. It is suggested that the maneuver can have clinical value in no cases save those of acute suppression of urine where it is a question of tiding over a brief period.

Atypical Poliomyelitis.—A case of poliomyelitis, contracted by a soldier in civil life before his departure for camp, is described by Schultz and Dannenberg. The earlier clinical course was that of an acute poliomyelitis involving the lumbar region cord. Xanthochromia and spontaneous coagulation of the spinal fluid were present, due to an old subdural hemorrhage which was the result of an injury three months before admission. The later course was complicated by infection of the urinary tract and by generalized infection, the result of paralysis of the bladder caused by the poliomyelitis. The organism which caused the secondary infection, while not a typical *B. proteus,* is apparently a member of the proteus group.

Thyroid Enlargement and Neurocirculatory Asthenia.—The object of the survey made by Addis and Kerr was to find whether those signs and symptoms which occur in neurocirculatory asthenia, and which may also be present in toxic goiter, were more commonly seen in recruits with thyroid enlargement than in those who had no thyroid enlargement. The findings were negative.

Chemistry of Pernicious Anemia.—A study of the chemistry of three cases of pernicious anemia is presented by Kahn and Barsky. The blood analysis showed a lessened specific gravity of the serum, reduction of the protein content, and increase in the ash and lime content, and a normal fat, cholesterol and glucose percentage. There was complete anacidity present in the stomach, an increased residuum, and absence of pepsin, resembling the gastric picture present in cases of carcinoma ventriculi. The Wolff-Junghans test was negative. Intestinal digestion was disturbed. The fecal bulk was much increased, and the nitrogen lost in the feces was above normal in amount. The fat in the feces was normal. Intestinal putrefaction, as evidenced by increased ethereal sulphate output, was present. There was a state of suboxidation—the neutral sulphur fraction was increased. The pancreas functionated normally, as evidenced by enzyme examination of duodenal contents and feces. There was a deficiency in the hepatic detoxication function as shown by the sulphoconjugation test. The glycogenic and ureogenic functions of the liver were normal. The excessive hemolysis of pernicious anemia was attended by both a pleochromia and urobilinocholia. In this regard Schneider's experiments are corroborated. There was an increased elimination of oxyproteic acid nitrogen in the urine in cases of pernicious anemia; the other urinary nitrogen fractions being normal. The renal function was normal, as evidenced by the phenolsulphonephthalein test and the blood nitrogen partition. The creatinin in the blood was increased. Acidosis was present in the cases examined, as determined by the carbon dioxid combining power of the blood plasma, the H ion concentration of the blood, and the carbon dioxid of the alveolar air.

Use of Sugar in Phosphorus and Chloroform Poisoning.—The facts presented by Simonds are, he believes, sufficiently well substantiated to justify the opinion that the administration of sugar will prove to be an important therapeutic measure in phosphorus and chloroform poisoning in humans, in acute yellow atrophy of the liver, and, possibly, in eclampsia.

Meningococcic Meningitis.—In four of ten moribund cases of epidemic meningitis seen by Olitsky, the meningococcus was found circulating in the blood. This finding, he believes, emphasizes the need of intravenous combined with intraspinal methods of treatment. Serums having a low agglutinin content were therapeutically ineffective. About 95 per cent. of the patients were infected with one type, the parameningococcus; the remainder with the irregular para type. In a series of prisoners, who lived under hygienic conditions, 24.6 per cent. were found to be carriers. Of these, 50 per cent. yielded irregular or inagglutinable types and 34.3 per cent. the normal type, and only one person the para type. Although the jail is within the epidemic area, not a single case of meningitis developed therein. These and other facts already stated have led to the conclusion that dense overcrowding of population and the presence of a pathogenic type of meningococcus, rather than the actual numbers of healthy carriers of various types of the organism, are the causes of the great spread of this epidemic.

Analysis of Pneumonic Exudates.—Biochemical studies of pneumonic exudates obtained from human lungs in the stage of gray hepatization were conducted by Weiss by the method of anaphylactic sensitization and intoxication of guinea-pigs with various proteins derived from normal and pneumonic lungs, exudates, serums, etc. The following observations were made: Pneumonic exudates, contain at least two toxic proteins: (1) a specific sensitizing protein apparently identical with the pneumotoxin which is liberated on the dissolution of virulent pneumococci, and (2) an extremely toxic, pyrogenic albumose. There are also present normal serum proteins: serum albumin and serum globulin, leukocytes and fibrin. Neither undigested pneumococcic protein nor albumin derived from the lung tissue, possessing sensitizing powers, are demonstrable. The globulin fraction of human pneumonic exudate is nontoxic and identical with similar normal globulin. The albumin fraction of pneumonic exudate is toxic and possesses marked specificity. This is ascribed to the digestive action of the enzymes of the exudate. The albumose fraction is far more toxic. Dyspnea, convulsions and death follow the intraperitoneal injection into white rats of doses of one 1 gm. per kilogram. Intrathoracic injection into rabbits of doses of 0.02 gm. per kilogram produces a rise in temperature, dyspnea, a hemorrhagic extravasation into the alveoli of the lung and an acute diffuse nephritis. On repeated intraperitoneal injections of this albumose into rats, a tolerance to it can be established. Large amounts of ether-soluble, nontoxic, hemolysis-inhibiting substances were extracted from pneumonic lungs. These are assumed to have the power of neutralizing the hemolytic activity of the pneumotoxin in vivo.

The formation of the exudate in pneumonia is considered by Weiss to be in part due to an increased permeability of the endothelial cells of the lung for various normal serum albumins, globulins, fibrinogen and enzymes as the result of the injury exerted by the pneumotoxin on their cement substance. The toxin is also regarded as a lymphagogue. It hinders the autolysis of the exudate and the favorable action of antipneumococcus immune bodies and thus produces toxic autolysis inhibiting, pyrogenic albumoses. With the development of excess amounts of specific antibodies, of bactericidal and phagocytic substances, and of a tolerance to the toxic albumoses, the deleterious influences of the toxins and albumoses are neutralized. Autolysis of influences of the toxin is now unhindered and the products are nontoxic aminoacids. The equilibrium of this system being governed by the laws of mass action, the change from febrile toxemia to the afebrile atoxic state is necessarily an abrupt one—crisis.

Boston Medical and Surgical Journal

March 20, 1919, **180**, No. 12

- *Influenza Epidemic at Camp MacArthur. L. S. Medalia, Boston. —p. 323.
- Pneumonia and Empyema. H. Gray, Camp Devens, Mass. To be continued.—p. 330.
- *Unique Case of Foreign Bodies in Stomach. A. C. Callister, Boston. —p. 334.
- Infantile Scurvy. J. Comby, Paris, France.—p. 336.

Influenza at Camp MacArthur.—In the epidemic in this camp the influenza bacillus was found to be the predominating organism. Out of 2,279 sputums examined by Medalia and others, 76.8 per cent. were found positive to this organism. The pneumococcus was the most important associated organism, being found in 53 per cent. of the total sputums examined. The examination of contacts for influenza carriers as a means of prev[illegible]n, though possible, was found impracticable. The ty[illegible] [illegible]ination [illegible] 440 cases of influenzal pneumonia conf[illegible] the fol[illegible]: T[illegible] 0.23 per cent.; Type IIa, 3.4 p[illegible]; Type I[illegible]; Type [illegible], 1.1

per cent., and Type IV, 85.8 per cent.; undetermined, being bile insoluble, 8.6 per cent. The *B. influenzae* was found in 54 per cent. of the bronchopneumonia sputums that were typed. Blood cultures made in 233 cases showed thirty-four, or 14.6 per cent., positive. Thirty-one of the thirty-four positive, or 94 per cent., were found to be pneumococcus. *B. influenzae* was found in two cases, or 5.8 per cent. (one mixed with pneumococcus). The high percentage of positive *B. influenzae* found in the bronchopneumonia cases that came to necropsy, in the lungs, pleural cavities, the heart, and spleen culturally, and in the stained tissue of the lungs and spleen, is accepted by Medalia as being further evidence of the causative relation of *B. influenzae* to the bronchopneumonia, and as demonstrating the frequency of the organism in the circulation. The sixty-one consecutive necropsies showed 92 per cent. to be bronchopneumonia; 8 per cent. lobar. Empyema (bloody serofibrinopurulent) was a constant finding, being present in over 75 per cent. of the cases.

Foreign Bodies in Stomach.—One hundred and forty-one foreign bodies were "fished" out of the stomach in Callister's case, including 128 sections of bed spring, measuring 8 cm. in length and 1 cm. in diameter on either end, nine copper pennies, three peach pits, and a piece of tin foil, the total weighing 2½ pounds.

Bulletin of Johns Hopkins Hospital, Baltimore

March, 1919, **30**, No. 3371.

Antituberculosis Measures. A. K. Krause.—p. 49.
*Insusceptibility of Monkeys to Inoculation with Blood from Measles Patients. A. W. Sellards and J. A. Wentworth, Camp Devens, Mass.—p. 57.
*Production of Tetany by Intravenous Infusion of Sodium Bicarbonate: Report of Adult Case. G. A. Harrop, Baltimore.—p. 62.
*Changes in Blood Immediately Following Transfusion. J. G. Huck, Baltimore.—p. 63.
Elizabeth Fry—Quaker Reformer. H. M. Thomas, Baltimore.—p. 72.

Insusceptibility of Monkeys to Inoculation from Measles Patients.—Three monkeys were inoculated by Sellards and Wentworth with the blood of measles patients taken early in the course of the disease from moderately severe cases. These animals remained entirely free from any symptoms that were either diagnostic or even suggestive of measles. Two of these animals that were injected a second time failed to develop any symptoms. After an incubation period of eleven days blood was taken from one of these monkeys and injected into a human volunteer. No symptoms developed.

Production of Tetany by Intravenous Infusion of Sodium Bicarbonate.—A woman swallowed bichlorid of mercury with suicidal intent. Because of reduction in plasma carbonate capacity she was given 500 c.c. of a 5 per cent. sodium bicarbonate solution intravenously. No untoward effect was noted and she said that she felt more comfortable afterward. Twenty-four hours later, another intravenous infusion was given of 700 c.c. of a 5 per cent. solution of sodium bicarbonate, prepared as before. This made in all 60 grams of sodium bicarbonate given intravenously. A small amount given by mouth had not been retained. About five minutes after this last infusion, which had been given slowly and had been apparently well taken, the patient's face suddenly grew pale, she commenced to have great inspiratory difficulty, and became very apprehensive. She complained of numbness and tingling of the fingers, and begged to have them rubbed. The hands assumed the typical obstetrical position, there was pedal spasm, and a first degree facial phenomenon (Chvostek's sign) was obtained. The pulse was accelerated to about 130, and the extremities became cold. There was no elevation of the blood pressure. The acute attack lasted for about fifteen minutes, after which the breathing became easier and she was less apprehensive. The *main d'accoucheur* position was maintained for about two hours. The following day the plasma bicarbonate capacity was eighty volumes per cent. On this day a second degree Chvostek's sign was obtained and Trousseau's phenomenon was easily elicited. Trousseau's phenomenon was present for four days and Chvostek's sign until the night of the seventh day, when the patient died.

Changes in Blood Immediately Following Transfusion.—Following the injection of blood, Huck found an immediate increase in the red cell count, the striking point being the marked increase in many cases apparently out of proportion to the quantity of blood introduced. In one case, the red count rose from 880,000 to 1,488,000 immediately after the injection of 500 c.c.; and in another case from 480,000 to 1,300,000, following the injection of 650 c.c. Such remarkable changes, Huck believes, apparently indicate a rapid redistribution of blood following an injection. In some cases the initial increase continued for several hours, usually falling, so that at the end of twenty-four hours the count had fallen to approximately where it was before the transfusion. In other cases, however, there was a marked increase at the end of twenty-four hours. In several instances, after injection of blood, the count fell for a few hours and then rose slightly. The hemoglobin in most cases showed a uniform rise following transfusion, usually reaching its maximum at the end of twenty-four hours. In some cases the hemoglobin fell slightly after the initial rise. Changes in hemoglobin did not run parallel with changes in the red count, as shown by the variations in the color indexes.

In practically every case following transfusion there was some increase in leukocytes. In several instances, however, they remained practically stationary or even fell. The most striking change in the differential count is the increase in the polymorphonuclear neutrophils. Occasionally, a neutrophilic myelocyte was seen following transfusion. In these cases no outpouring of nucleated red cells occurred, although in four instances a few were seen following transfusion, but not before. The numbers are so small, however, that this may have been accidental. A general review of the immediate effect of transfusion on the blood count in twenty cases does not reveal any constant changes following this procedure. The point of practical interest and importance seems to be that no exact mechanical effect can be demonstrated following the introduction of definite quantities of blood. Whereas, in a general way, it may be said that the introduction of blood raises the count, the effect is essentially a biologic one involving the redistribution of blood in the body, and its exact nature is not at present understood.

Bulletin of Lying-In Hospital of City of New York

March, 1918, **11**, No. 4

*Open Air Treatment in Anemia Due to Repeated Hemorrhage. J. W. Markoe, New York City.—p. 209.
*Toxemias of Pregnancy and Their Treatment. A. B. Davis, New York City.—p. 212.

Causes of Death in Childbirth; Maternal Mortalities in 100,000 Confinements at New York Lying-in Hospital. J. A. Harrar, New York City.—p. 257.

Open Air Treatment in Anemia.—In cases of severe hemorrhage from any cause other than the blood diseases, when the bleeding is controlled before a fatal amount has been lost, Markoe has adopted the open air treatment, placing the patient directly out of doors, or, where that is impossible, he has moved her into the room containing the greatest cubic air space and the largest number of windows. Markoe also follows this procedure in many forms of septic infection in which efforts to build up the resistance of the patients seems unavailing until they are placed in the open air with proper surroundings.

Toxemias of Pregnancy.—The treatment of the preeclamptic state employed by Davis consists of milk diet, 2 to 3 quarts of milk in twenty-four hours; a hot bath daily, colonic irrigation with bicarbonate of soda solution, and a saline cathartic, preferably magnesium sulphate. Bicarbonate of soda given by mouth will reduce or entirely cure the heartburn and acid indigestion. This course is followed for a week or ten days. As improvement appears the patient is allowed out of bed part of the day. Gradually cereals, eggs and nonnitrogenous foods are added to the diet. The daily hot bath, mild saline catharsis, milk and cereal diet and bicarbonate of soda are continued. The treatment of the eclamptic state: stomach lavage with bicarbonate of soda solution, followed by 2 ounces of magnesium sulphate. The colon is irrigated, employing from 4 to 5 gallons of normal salt, glucose or soda solution. Davis prefers soda solution. The essential thing is the large quantity of fluid introduced which clears the colon and by absorption flushes the kidneys, in this way proving to be the best diuretic. Stimulate all the emunctories; dilute and remove as much toxic material as possible. Very little internal medication is used. Chloral hydrate, sodium bromid, and morphin usually comprise the list. In operative deliveries, ether is used as a rule, chloroform never, rarely gas and oxygen. If the condition of the patient demands it, immediate delivery is done.

Rôle of Thymus in Exophthalmic Goiter.—In an attempt to determine whether an excess of the product of thymus activity in the circulating blood could cause exophthalmic goiter or not, experiments were made by Eddy on rabbits. Two rabbits served as a control. Three rabbits were given hypodermic injections of thymus substance in the proportion of 5 mgm. per kilogram of body weight, and three in the proportion of 10 mgm. per kilogram. Forty injections were given to each rabbit. There was no evidence of the production of symptoms characteristic of exophthalmic goiter by the thymus gland substance employed in either group of rabbits.

Pneumonococcus Infection and Endocardial Lesions.—The postmortem examination of seven horses immunized against Types I, II and III of the pneumococcus showed that horses undergoing active immunization by the intravenous inoculation of living virulent pneumococcus cultures develop infectious processes locally in the joints and in the tissues of the organs, but especially in those of the heart, including the heart valves. These lesions are intimately associated with injury of the blood vessels due to the action of the pneumococcus poisons, and are thus infectious processes in which the bacterial development may be evanescent and promptly followed by complete resolution or by reparative processes with scar tissue, or the bacterial development may persist, inciting varying degrees of inflammatory reaction and necrosis before the bacteria are destroyed and the reparative process heals the injury. All stages of these lesions were found in the heart valves: petechial and larger hemorrhages with and without inflammatory reaction and larger and smaller areas of necrosis in which pneumococci were present in large or small numbers or absent altogether, all in various stages of development, resolution and repair.

Wadsworth calls attention to the fact that these lesions correspond with those of acute and chronic endocarditis in man. The anatomic changes of the ulcerative or vegetative and the sclerosed lesions in man are all to be found in these lesions of the horse. It is, therefore, not necessary to assume that the chronic lesions of endocarditis in man, however slight or marked, or however free from evidences of bacterial activity, have not been originally infectious processes. The importance of predisposing injury determining the localization of the bacteria is also demonstrated by Wadsworth, but it is evident that the bacterial poisons produce this injury so that the bacterial localization may be practically coincident with it or follow it immediately. It also appears that in these experiments on the horse, and doubtless also in the disease as it occurs in man, the endocardial lesions arise from injury of the bacteria and their poisons carried to the endocardial tissues through the coronary circulation and not from the direct action on the endocardium of bacteria and their products passing in the main blood stream of the ventricles and auricles. Wadsworth points out that in order to clarify our conceptions of pneumococcus infection, and doubtless also streptococcus infection, it is necessary to recognize the parasitic and the toxic activities of the inciting agents as being distinct phases of the infectious processes and yet not as entirely separate or independent activities because they are in point of fact closely linked and largely, if not wholly, dependent one on the other.

Typhoid Bacilli Injected into Rabbits.—An attempt was made by Parker and Franke to demonstrate some difference in either the killing or localization of typhoid bacteria in normal and immune rabbits. Their results were entirely negative in regard to the killing of the bacteria. Both in normal and immune animals the bacteria are taken up and killed in the organs with extraordinary speed. The lungs of immune rabbits, however, take up a slightly greater number of bacteria than do normal lungs.

Diffuse, Indolent Ulceration of the Intestine.—The lesion reported by Crowdy was found during [illegible] ortem nation of the body of a man who died of bronchopneumonia following empyema. The large intestine showed an indolent ulceration, most marked in the cecum and ascending colon. The dependent part of the cecum escaped to a large degree, but close to the ileocecal valve was a large irregular ulcerated area (about the size of a 50-cent piece) in which the mucous membrane was entirely lost, except for a few very small, irregular strands. In the ascending colon the surface of the mucous membrane had a honeycombed appearance, being made up of innumerable small, irregular, shallow, pale ulcers with sloping necrotic margins separated by about an equal amount of degenerating mucous membrane. Toward the hepatic flexure the ulceration became less diffuse, and large, isolated and irregularly outlined ulcers occurred, giving the mucous membrane a moth-eaten appearance. These gradually diminished in number and disappeared near the splenic flexure. The lower end of the ileum also showed a few scattered irregular ulcers similar to those in the transverse colon and extending upward for about 90 cm.

A considerable number of sections, both from the ileum and cecum, were stained by the Gram-Weigert method, with the following result: On the surface of the intestine, the usual numerous forms of bacilli and cocci were present. Within the tissues, however, a large mycobacillus of marked pleomorphism was to be seen. A very common form was a long, thick rod with rounded ends, which stained in alternating darker and lighter segments. This was found in the submucosa beneath the ulcers, and in the islands of the mucosa. With it occurred spherical coccoid bodies, and transitions to bacilli. They were diffuse, in bunches or isolated. A second, also common, form was an elongated, club-shaped, frequently curved or bent, slender organism carrying conidia at one pole, often resembling an exclamation sign, or spermatozoon in shape. This appeared in various modifications and transitions. In some of the smaller veins and capillaries other forms of apparently the same micro-organism were detected. The character of the threads and apparent lack of true branching point to cladothrix.

Identifying Culture Medium for Colon-Typhoid Group of Bacteria.—Bronfenbrenner and his associates use fresh milk and milk-whey for culture material. It is prepared as follows: Heat fresh milk in the Arnold sterilizer for fifteen minutes, place on ice for eight to twelve hours; separate the cream; dilute one part of milk with three parts of water; add indicator (CR [mixture of China blue and rosolic acid]) at the rate of 2.5 c.c. per hundred c.c. of diluted milk; boil for five minutes; if too acid adjust the reaction until pale gray color is obtained; distribute in sterile tubes containing inverted vials, and autoclave at 15 pounds pressure for ten minutes. In the preparation of milk-whey medium, use fresh milk; siphon the milk from under the cream; bring it to boiling and add 2.5 c.c. of 10 per cent. $MnCl_2$ solution to each 100 c.c. of milk; cool the mixture as soon as the clot is formed and filter through a single layer of cloth; titrate an aliquot portion hot and adjust the bulk of the medium to neutral reaction ($1x10^{-7}$); bring quickly to boiling, cool and filter through paper; dilute the filtrate with double its volume of water and add 1 c.c. of CR indicator for 100 c.c. of medium. (At this point the medium will have an intensely blue color.) Dilute into sterile tubes containing inverted vials and autoclave at 15 pounds pressure for ten minutes. Immediately after autoclaving the medium will have a pink color. On cooling it will become colorless if it is properly neutralized. However, a slight tinge of blue or pink will be very easily distinguished from the intense color due to the progressive change in hydrogen ion concentration during the growth of the culture.

In making milk-whey agar, an agar jell of 3 per cent. concentration in plain water is sterilized and diluted with an equal volume of neutralized milk-whey. While the mixture is hot add CR indicator at the rate of 0.5 c.c. for each 100 c.c. of medium, distribute into sterile tubes and sterilize for ten minutes at 15 pounds pressure. In the authors' experience, this medium is fully as useful as lactosepeptone water or lactose agar, but cheaper and easier to prepare.

Bacteriology of Canned Foods.—Bacteriologic examinations were made by Weinz[illegible] of 1,018 samples of canned goods. The organisms isolated from these 1,018 samples of canned goods comprised yeasts, molds, and bacteria. The most prevalent species of bacteria were *B. mesentericus, B. subtilis, B. thermoindifferens, B. vulgatus* and *B. cereus.* The most prevalent mold was *Aspergillus nidulans.* In commercial canned foods giving no evidence of spoilage, micro-organisms were found in 179 out of a total of 782 cans, or in 23 per cent. of the cases. After the food is processed, the spores remaining alive in the cans are unable to develop because of the absence of free oxygen. When air is admitted the spores may germinate and spoil the food. Members of the paratyphoid-enteritidis group were not found, nor was *B. botulinus* ever isolated.

p.Acetyl-Amido-Ethoxy Benzene. — The pharmacologic actions of pertonal (acetyl-amido-ethoxy benzene) have been investigated by Cow and a comparison made between it and phenacetin. Pertonal possesses approximately one half the toxicity of acetphenetidin (phenacetin) and as an antipyretic it produces similar effects in doses approximately double those of acetphenetidin. Acetphenetidin exerts a directly depressant action on the heart, which is actually stimulated by pertonal. Against an antipyretic ratio of 2 parts of pertonal to 1 part of acetphenetidin, the corresponding ratio for narcotic action is approximately 15 to 1. In general the action of pertonal is less abrupt and more prolonged than that of acetphenetidin. Both drugs are excreted mainly in the urine in the form of p. amidophenol and phenetidin. It appears that a larger amount of phenetidin and a correspondingly smaller amount of p.amidophenol is set free in the tissues by pertonal than by acetphenetidin. No evidence of methemoglobin formation has been found after pertonal, whereas this change is often found after acetphenetidin. No evidence of oxalic acid formation after pertonal has been found, though this was specifically sought for. A range of therapeutic dose of 10 to 20 grains or more is recommended: it is suggested, too, that the dose need not be repeated so frequently as the dose of acetphenetidin.

Pharmacologic Action of Allocain S.—Allocain S. and Allocain A. are synthetic products made by Nagai by introducing into mydriatin mono-ethyl and di-ethyl and benzoyl groups. Kubota studied the pharmacologic action of Allocain S. He found that it causes paralysis in frogs and convulsions in rabbits, acting on the central nervous system. The lethal dose, when injected subcutaneously, is smaller than that of cocain and procain. It causes a local paralysis of sensory nerve endings and nerve fibers, and its anesthetic power is stronger than procain and weaker than cocain. Allocain S. has a twofold action on blood vessels: a primary dilation and a secondary constriction, and in warm blooded animals the former action, and in cold blooded animals the latter appears more marked. Subcutaneous injections of Allocain S. cause a slight local irritation. A great amount of it paralyzes the heart, acting on the motor apparatus and conductive system, and causes in frogs a paralysis of respiration and in rabbits a stimulation of it, which action seems to be the central character. The blood pressure is influenced by Allocain S. The substance produces a primary fall of pressure which is followed by a rise above the normal. It inhibits the growth of both streptococci and staphylococci. Allocain S. is a good local anesthetic in many respects, but on the other hand it has also some unfavorable qualities. On account of the slight irritation by its acid solutions and of its precipitation by tissue fluids, its use is limited. Allocain S. has been tried in several hundred cases of operation with success.

Effect of Atropin on Ether Hyperglycemia.—The animal experiments made by Ross showed that atropin reduces markedly ether hyperglycemia; the greatest reduction is in the first fifteen minutes.

Influenzal Pneumonia.—As the great majority of patients extremely ill showed typical signs of shock, various efforts were made by Rood and his associates to combat this condition but no results beyond a temporary improvement were observed. The fluid extract of ergot was used with good temporary results. Ergotin was used with no noticeable action. Epinephrin and pituitary extract were practically useless, neither producing any rise in blood pressure or even a transitory stimulation. Alcohol in any form was seldom used. Locke's solution with 13 per cent. acacia was given in a number of cases intravenously, in order that the presence of a colloid might possibly prevent, to a certain extent, the absorption of toxin, and, at the same time furnish a diluent. This solution gave the most striking results, improvement often being immediate and continuing from six to eight hours. It gave best results when given from two to three times a day, at six or eight hour intervals. Bromids in full doses when the patient was restless and unable to sleep. Occasional doses of chloral hydrate were given either for its direct hypnotic action or to fortify the effect of bromid. Codein was used in preference to morphin to relieve pain and troublesome dry cough. Expectorants and narcotics of all kinds were avoided as most of these patients were already half drowned with exudates. Morphin was used only as a last resort or when pain could be controlled in no other way. Immune serum obtained from patients who had been convalescent from the disease for seven to ten days, was used in six cases, with curative results in only one instance. In most of these cases it did not appear to influence favorably the course of the disease in the least degree. Results obtained by oxygen were transitory, and as the condition progressed the cyanosis became as pronounced as before.

It was noted that often the patient was greatly relieved by lung puncture, especially if a pneumothorax followed the operation, and it was not uncommon for patients to request that the operation be repeated. Patients frequently showed a drop in temperature following puncture and a temporary improvement in physical signs. The cough and sputum would increase for a short time, followed by a marked decrease in the number of râles within a few hours. The results following this procedure led to the opinion that the production of a slight positive pressure in the side showing greater involvement might materially aid in compressing the profuse exudate from the affected lobes. With this purpose in view, an artificial pneumothorax was produced in three patients, in the hope from 100 to 150 c.c. of air into the pleural cavity, in the same manner as has been frequently carried out in the treatment of tuberculosis. These three cases were considered hopeless at time of injection. Two of the patients recovered, but the third one, whose case was considered hopeless, being intensely cyanosed, delirious, and moribund, became conscious and rational, and very few râles were to be heard in the chest of the side operated on and breath sounds were quite distinct. He continued to improve for thirty-six hours, when he again became delirious and comatose, dying forty-eight hours after operation.

Appendicitis.—Abstracted in The Journal, Nov. 23, 1918, p. 1769.

Fallacies of Colonic Irrigations.—Mills and Bird point out that when more than 4 or 5 inches of tube are inserted into the rectum it coils on itself, the end of the tube turning and coming back to the anus and, although apparently this does not interfere at all with the passage of the solution, as it is shown to have traversed the full length of the colon in spite of the coils, the occurrence of this coiling naturally suggests the question of the advisability and necessity of passing so much of the tube into the colon. The apparatus tested by the authors consists of a container for the fluid, held 18 to 24 inches above the level of the patient, to which is attached a rubber hose, at the end of which is a glass or hard rubber tip, and a soft rubber rectal tube or catheter. They first pass the well-oiled rectal tube or catheter into the rectum about 2 inches, the child lying on its back or left side on a Kelly pad. The tube is held in this position for a few minutes to allow of the escape of gas, as it has been found that the pain frequently complained of during colonic irrigation is entirely avoided if the gas is first gotten rid of. It is equally important to rid the tube attached to the container of all air by letting a few drops of the fluid pass through. The free end of the rectal tube or catheter is then slipped over the glass or hard rubber tip so that continuous connection exists between the child and the solution to be used, and the catch is then gradually sprung so that the fluid begins to flow slowly into the colon, the insertion of the rectal tube or catheter being at the same time gradually increased, often to a distance of 8 or 10 inches or more. The fluid used is usually either normal salt or 2 to 5 per cent. sodium bicarbonate solution; the temperature is about 100 F., and the quantity employed is rarely less than 2 quarts, and much more if it is not returning clear. The rectal tube or catheter has two holes at the end to be inserted in the rectum, one at the tip and the other at the side about one-half inch from the tip, so that should one become plugged with mucus or fecal matter, the solution would pass through the other. When the colon is fully distended contraction takes place, which expels much of the contents, as shown by the squirting of the returning solution along side of the tube, so that there need be no fear of too much fluid being used. Massage of the abdomen when the colon is distended with fluid is often beneficial.

*Treatment of Acute Gonorrhea: Massage-Pack Method. J. P. Fogarty. —p. 245.

Defense of Respiratory Membrane Against Influenza.—To combat the influenza infection, Hill urges the deep breathing of cool air, brought about by exercise, sleeping in open air, and as an adjunct any spray, gargle, or snuff which enhances the outflow of secretion from the respiratory membrane of the nose and throat. He says that the wearing of a mask, by raising the temperature and humidity of the air breathed, is against the natural defensive mechanism. The natural defense must be raised by the discipline of open-air exercise and by proper housing.

Treatment of Influenza.—Groups of patients—fifteen in each—were put on different drugs by Small and Blanchard and the progress of the various groups noted and compared. Aconite, acetylsalicylic acid, sodium salicylate, belladonna, arsenic, quinin, Dover's powder, and gelsemium were tested in this way. The patients treated by gelsemium improved in a manner far exceeding those given any other treatment. After a few doses headache and backache had been much relieved, and the patients felt greatly benefited in every way. In most patients, the temperature speedily commenced to fall, and the improvement in the general condition was obvious. Of the other drugs tested, belladonna showed evidence of beneficial action in a number of cases, but none of the other drugs appeared to have the slightest influence. The patients were not selected in any way, but were taken consecutively as they were admitted. All recent cases, therefore, have been treated with the following mixture:

	gm. or c.c.		
℞ Tr. gelsemii	73		♏ xij
Tr. belladonnae	33		♏ v
Potassii citratis	66	or	gr. x
Syr. aurantii	4		℥ j
Aq. chloroformi ad	30		℥ j

Sig: One ounce four hours for the first 24 hours; thereafter ½ ounce every four hours until temperature is normal.

Potassium citrate is added as a mild diuretic. When the temperature reaches the normal the remedy should be stopped.

Acriflavine Emulsion as Wound Dressing.—The formula (Humphrey's) of an emulsified preparation of the dye endorsed by Stowell is as follows: Acriflavine, 0.1; thymol, 0.005; white wax, 4.0; liquid paraffin, 76.0, and distilled water, 20.0. This emulsion is put up in small sterile bottles, stoppered and sealed. The addition of the thymol has given better results in cases of mixed infection, and its presence has not prejudiced the results in the simpler cases. In dealing with broken down tuberculous glands, after scraping, Stowell introduces a small quantity of the emulsion before closing the wound.

Treatment of Acute Gonorrhea.—It is now an Australian Army Medical Corps order that the massage-pack method of early treatment of gonorrhea shall be used to the exclusion of all others. The treatment consists in packing the anterior portion of the urethra with a material soaked in a silver solution. The pack not only absorbs the discharge and drains the infected part, but, by mechanically dilating the urethra, it enhances the prospects of the chemical reaching the site of the infection, and prevents apposition between infected and noninfected surfaces. For packing, Fogarty has found soft gauze far superior to cotton-wool. It is more absorbent, less irritating, and is more easily passed into and withdrawn from the urethra; it has no tendency to break, and shreds are not detached from it. In the large majority of cases argyrol has been used. From a curative point of view an argyrol solution stronger than 5 per cent. is not necessary, and 7 and 10 per cent. show a tendency to cause soreness, necessitating less frequent packing, thus depriving the patient of the benefit of the mechanical advantages of the pack. Fogarty has found hemorrhage even with 10 per cent. a rare occurrence, and not in one single instance with 5 per cent. There were only seven failures in 742 cases treated.

Detoxicated Vaccines.—Thomson has conducted extensive researches on the removal of the endotoxins from the gonococcus and other organisms in order to produce nontoxic vaccines which could be injected in sufficiently large doses to develop a great amount of immunity. The toxicity of most germs was successfully reduced some fifty to 100 times. Thus, with ordinary gonococcal vaccine it was found necessary to begin in acute cases with doses not exceeding 5 millions and gradually to increase to about a maximum of 250 millions. On the other hand, the same strains of gonococci when detoxicated could be administered in acute cases in doses of 2,500 millions and increased to 10,000 millions. These large doses caused even less toxic symptoms than the small doses of the ordinary vaccine.

The therapeutic results obtained corresponded very markedly with the serologic tests. Thus it was found that the cases which showed the highest degree of immunity as estimated by the complement-fixation test recovered much more devoted to physiotherapy, as he was an international authority rapidly, and vice versa in those which showed a low degree of complement fixation the disease ran a prolonged course. The dose of 200 millions of ordinary gonococcal vaccine produced malaise and fever in the normal subject, whereas the symptoms arising from a dose of 5,000 millions of the detoxicated vaccine were scarcely noticeable and no fever was induced. Experiments have been carried out with detoxicated vaccines for the prevention and treatment of bronchial and nasal catarrh and the results so far have been very promising. Thomson says that the clinical evidence is increasingly convincing that this detoxication process will revolutionize the whole subject of vaccine treatment and preventive inoculation.

Spirochetes in Blood in Trench Fever.—In two out of six cases of trench fever Coles found a few spirochetes or spirochetal-like bodies in one or two of the many films examined. These structures vary considerably in their form, but they have in common the fact that with Giemsa they are all stained a delicate blue tint; they are all faintly granular, and in no case are the ends pointed. Whether they have any actual causal relation to trench fever, Coles does not say. The fact that they were detected only in the blood of definite cases of artificially induced trench fever, and then only during the first attack of fever, he believes is at least suggestive.

Attenuation of Tubercle Bacilli.—The effect of long continued and regular subculturing of pure cultures of human, bovine, and avian tubercle bacilli on artificial mediums containing glycerin is reported by Raw. This process has been continued without interruption for twelve years and the cultivations are luxuriant and grow as readily as in the first year of subculturing. They retain all their characteristics and selective appearances, and can easily be identified as distinct types of tubercle bacilli. The real object of this work was to find out if it was possible to reduce the virulence of the bacilli to such a degree that it might be possible to use them therapeutically in the treatment of active tuberculosis. In 1914, several animals were inoculated with bacilli of nine years' attenuation with practically negative results. In no case was any progressive tuberculous process set up in the animals, and postmortem examinations showed no active tuberculosis. Eight cases of apparently hopeless tuberculosis of the glands, bones, joints and lupus; all discharging sinuses were treated with injections of living bacilli at intervals of one week. The injections were made subcutaneously in the triceps region, and aside from redness and slight swelling no bad effects were observed, and the patients noticed nothing unusual. Later, four cases of acute and active pulmonary tuberculosis with large numbers of bacilli in the sputum were treated in the same way. All these patients are still living, and a full report will be published after an interval of five years from the date of treatment. In all of the cases treatment with mixed bacilli was given, the cultures being raised to a temperature of 220 F. for two minutes before injection.

*Gangrene of Lung and Pneumothorax. A. de Verbizier and Loiseleur.—p. 1139.
*Nervous and Mental Sequels of Icterohemorrhagic Spirochetosis. S. Costa and J. Troisier.—p. 1142.
*Benzol in Myeloïd Leukemia. H. Bourges.—p. 1149.
Hyperthyroidism Following Emotional Stress, with Hypertrophy of Parotid Glands. G. Railliet.—p. 1151.

Diagnostic Importance of Sugar and Urea in the Cerebrospinal Fluid.—Dumolard relates that in eighteen of seventy cases of nervous or mental disturbance, at a special army neuropsychiatric center, the cerebrospinal fluid showed an abnormally large proportion of sugar or of urea or of both combined, without any reaction on the part of the leukocytes, and without hyperalbuminosis. In the other cases there was sometimes an excess of sugar or urea but there were other reactions evident as well. In these eighteen cases the sugar content was over 0.80 gm. and the urea over 0.25 gm. per liter, and all these men presented severe nervous or psychic disturbance. The tabulated findings suggest that in the sugar and urea content of the fluid we have an early sign of pathologic conditions, the first revelation of organic disturbance in the functioning of the nervous system. In some of their cases there were evidences of meningeal hemorrhage, softening of the brain or epilepsy, jacksonian in one case.

Gas Gangrene.—Sacquépée discusses the pathogenesis of gas gangrene and the action of serotherapy according to the effects of the specific serum on guinea-pigs. This indirect test, the "protected guinea-pig test" as he calls it, is based on the specific protection conferred on the animal by the antitoxic serum against inoculation of the corresponding pathogenic microbe. An emulsion of a scrap of gas gangrene tissue containing one or more of the pathogenic species kills the guinea-pig. But if the guinea-pig has been previously protected by the corresponding antiserum, the animal will survive while the controls all die, as also those animals protected only with an antiserum specific for other microbes than the one directly involved. In their twenty-five experiments, the *Bacillus bellonensis* was found alone or associated in fifteen, the perfringens in fourteen, and the septic vibrio in nine of the total twenty-five.

Gastric Juice in the Fasting Stomach.—Ramond and Robert found in normal soldiers that the fasting stomach was empty on the usual meat diet. But on a milk diet, and also on a purely vegetable diet, gastric juice was found in the fasting stomach quite often. In the dyspeptic, gastric juice was found in the fasting stomach in 66 per cent. of 100 examined, but the amount of hydrochloric acid varied with the amount of meat in the diet. In the mild cases the meat seemed to reduce the hydrochloric acid content, and thus aided in the prognosis. The amount of gastric juice ranged from 20 to 50 c.c. in ordinary dyspepsia; above 100 c.c., some degree of stenosis can probably be assumed. In the discussion it was emphasized that traces of food always indicate more or less stenosis of the pylorus. The general conclusions of Ramond and Robert are to the effect that gastric juice can be found in the fasting stomach even in normal persons on a vegetable diet, but there should not be any present on a meat diet. In the dyspeptic, gastric juice is found in the fasting stomach, but this gastrosuccorrhea, although almost constant, has no pathologic significance unless it is profuse and continuous, and is uninfluenced by modification of the diet.

Gangrene of Lung Heals Under Induced Pneumothorax.—De Verbizier and Loiseleur witnessed the development of a focus of gangrene in the lung a week after the onset of grave influenza with involvement of the right lung. The resulting cavity was partially drained into the bronchus but not adequately, and the general condition was growing graver. The roentgen rays showed the clear outlines of the gangrenous cavity, and by inducing artificial pneumothorax this compressed the lung so effectually that the contents of the cavity were squeezed out. The walls of the cavity were thus pressed together, and definite healing soon followed. They state that in fifteen days the rays showed integral restitution of the parenchyma of the lung. During the interval, the 200 c.c. of air that had been injected were completely absorbed and the diaphragm was functioning clinically normally. Success with this technic naturally depends on the possibility of an effectual pneumothorax and on the cavity draining into one of the larger bronchi. It would be dangerous to compress a gangrenous focus connecting merely with one of the smaller bronchioles.

Nervous and Mental Sequels of Icterohemorrhagic Spirochetosis.—Costa and Troisier have previously described what they call the psychomeningeal form of this spirochetosis. They here report three additional cases, and call attention to the coincidence in the same patient of psychic disturbances, impairment of vision and modification of the reflexes, demonstrating the profound, durable and widespread damage of meninges, brain and medulla possible in icterohemorrhagic spirochetosis. Mania and confusion persisted even after recovery, and mental weakness with instability and irritability was marked in all three of the patients. One presented stigmata suggesting degeneracy but the others seemed to be free from any predisposition of the kind. The existence also of organic sequels, especially renal, sustains the connection between the mental impairment and the spirochetosis. This psychomeningeal form was observed only in the graver cases, with uremia (one with very high urea content in the spinal fluid), dilatation of the heart, prostration, anemia, intense jaundice, photophobia, and extreme tenderness of the eyeballs. The Wassermann reaction is usually positive during this spirochetosis but veers to negative during convalescence; in one of the men it has persisted positive during the year to date, and there is nothing otherwise to suggest syphilis. One of the men presents also a double Babinski with exaggeration of the tendon reflexes, suggesting tenacious injury of the pyramidal tracts. Weeckers and Firket have reported cases of iritis and even a curable optic neuritis for which the icterohemorrhagic spirochetosis was evidently responsible.

Benzol in Myeloid Leukemia.—Bourges treated with benzol a man of 35 presenting symptoms of myeloid leukemia, giving 100 drops in milk three times a day. Gastro-intestinal disturbance and albuminuria the second day compelled the reduction of the dose to 50 drops, gradually returning to the former dose. This was kept up for two months and a half, with intervals of suspension every ten days, and marked improvement was evident. He gave up the treatment then, but returned ten months later in a very precarious state. Resumption of the benzol then failed to relieve and the man died in two weeks. During the first stage of treatment the blood improved, the spleen became reduced in size, the number of reds increased while the leukocytes and myelocytes became much reduced in numbers, and the whole condition showed pronounced improvement. It is therefore in the early phase of leukemia, during the almost latent stage, that benzol produces its finest effect. It seems advisable also to continue it for several months at a time, with possibly roentgen exposures in the intervals. This case, with others on record, teaches the wisdom of beginning with small doses, testing the susceptibility of the patient.

*Vomiting in Infants. A. B. Marfan.—p. 1.
*Increase in Weight During First Year of Life. L. Broudic.—p. 13.
*Emergency Surgery on Infants. R. Flament.—p. 23.
Child Welfare Legislation in France. A.-B. Marfan.—p. 32.

Vomiting in Infants.—Marfan discusses accidental and habitual vomiting in infants and cyclic vomiting, warning that sudden vomiting in the midst of health may be the first symptom of infectious disease. The temperature should be taken and signs of meningitis be sought, or of special intolerance for cow's milk, or signs of a strangulated hernia or invagination. Vomiting by a new-born child should suggest the possibility of congenital stenosis or imperforate anus. Only after all these causes have been excluded, should we think of a gastric origin for the vomiting. The symptoms of acute indigestion subside when the stomach and bowel have been emptied, which is important in differentiation of the cause of the vomiting. He does not give a purge or emetic, as this often seems to aggravate the condition. Restriction to water, with a few enemas, cures the child. The cause of the acute indigestion is an overabundant meal, especially when the preceding meal has not had time to complete its digestion, or a new dish may be the cause of vomiting. Some physicians have noticed that exposure to prolonged cold may induce indigestion and vomiting in infants. With bowel trouble, vomiting is usually an associated symptom, not taking the prominent place except possibly at the onset of trouble. Occasional regurgitation in infants is physiologic, but habitual regurgitation indicates that the child is gettng too much food. Breast fed chldren are the ones that present it most frequently, as they can tolerate overfeeding longer. Repeated hiccuping also indicates that even if the food is well digested, the child is getting too much. Excessive drooling has the same significance. Moderate drooling may occur because the infant does not know how to swallow saliva. It may accumulate in the mouth and throat and make the breathing noisy, suggesting stridor, etc. Up to the fourth or fifth month very little saliva is secreted. After this, coryza or adenoids may force the child to keep its mouth open and all the saliva may drool out although the amount secreted may be only the normal quantity.

Increase of Weight During First Year of Life.—Broudic gives the average weight of 112 infants as recorded at birth and at regular intervals thereafter. His records include really 2,000 infants but he was not able to have them all weighed at the specified intervals, so he bases his tables on only 300. Only one third were breast fed. These children increased in weight regularly and rapidly during the first six months, more slowly during the last six months. Only a few doubled their weight at birth by the fifth month, but even in this group the weight at birth had not trebled by the close of the year. The increase in weight is irregular with bottle fed babies; slow during the first three months and more rapid during the second three months. Infants given both breast and bottle increased in weight more regularly, like the breast fed. Whatever the mode of feeding, the weight shows comparatively little increase from the twenty-sixth month on, and the weight may remain stationary for a time or even decline. These irregularities are particularly manifest after the twenty-ninth week. He gives a chart and various tables and emphasizes the difference between his figures and those of others. The 2,000 infants were examined under the auspices of the Union maternelle of the fourteenth arrondissement of Paris. The average weight at birth was 3,280 gm.; at 5 months, 6,250 gm.; at 6 months, 6,710 gm.; at 1 year, 8,770 gm.

Emergency Surgery for Infants.—Flament refers to strangulated hernia, invagination of the bowel, osteomyelitis, mastoiditis and imperforate anus. With strangulated hernia he succeeded in overcoming the spasm, with the spontaneous retrogression of the strangulation, in seven among twenty-nine cases; in the others an operation was required and only two of the children died; the strangulation in these was of long standing. In seven spontaneously retrogressing cases he had had the child put at once into a warm bath. Gentle, cautious massage is allowable. Hot compresses can be applied for an hour or two, and with a few drops of chloroform the hernia may be reduced, but extreme gentleness and caution are necessary as the intestine is already damaged by the strangulation. Some device, like a hot water mattress under the infant, to ward off chilling during the operation, is indispensable. With invagination, the prognosis depends on the early diagnosis and prompt intervention, within the first twelve hours. The death rate runs up to 37, 54 and 78 per cent. the second, third and fourth days. Osteomyelitis in infants may be traced to the inadequate protection afforded by the skin. Flament recently encountered vertebral osteomyelitis in a 4 months infant, and osteomyelitis of the femur in one only 6 weeks old, and in the hip joint in one of seven weeks. Mastoiditis is merely osteomyelitis of the temporal bone, and in the twenty-one cases in infants in the clinic there had been preceding otorrhea in fifteen. The outer wall of the mastoid antrum is extremely thin in infants, and spontaneous trephining occurred in twelve of the twenty-one cases. The surgeon has only to enlarge the spontaneous opening. In infants the antrum is a little above and back of the external auditory passage, different from its location in older children. Only by prompt intervention can meningitis be warded off; five of twenty-one infants died from this cause. In operating for imperforate anus it is important to apply an appropriate technic; a simple incision may entail stricture. The rectal ampulla should be loosened and fastened to the skin, even if this requires a laparotomy. This combined operation was done recently on a day-old babe with complete success to date, three years later.

Radiotherapy of Fibromas. G. Réchou.—p. 100.
Errors and Prejudices with Mechanotherapy. Sandoz.—p. 103.
Bedside Roentgen Examination. J. Chatelain.—p. 108.

Accidents from the Roentgen Rays.—Weil had charge of the preparation of this special number of the *Paris Médical*, devoted to physiotherapy, as he was an international authority on this subject, but the first page is devoted to his obituary. His recent untimely death was mentioned in the Paris Letter. His article heads the list of contributions, analyzing his personal experience as chief of the laboratory of electroradiology at the hôpital Trousseau. He calls "accidents" all modifications of the human organism not foreseen or not sought when the roentgen rays have been used, and he describes and classifies them under various headings. He says that it is important to bear in mind that any ulceration which develops without pain, at least during the period of its development, is not a roentgen ulceration. The rays may have been applied in treatment of some tuberculous or other lesion, and the latter may have progressed to ulceration. If the ulceration is not painful, the roentgen rays cannot be incriminated for it. There is not much danger of confounding a tardy roentgen ulceration with a tertiary syphilitic lesion, but this mistake has occurred in the past. The general disturbances, fever, toxemia and weakness during roentgen treatment of cancer are due to the efforts of the organism to throw off the products of the cancer, but nausea, vomiting and exhaustion may be from the ozone generated during the exposures. This assumption is sustained by the appearance of these symptoms sometimes in the nurses and attendants in the room.

Weil declares that the serious cutaneous lesions that develop soon after a series of exposures can be warded off by modern technic with almost positive certainty, but this cannot be said of cutaneous lesions that may develop tardily. Modern technic has reduced the chances of this to the minimum, but cannot guarantee against these distressing eventualities, not even with the most forewarned and careful radiologist, especially so long as our instruments for gaging the rays are only relative and so imperfect. Radiotherapy, like all active therapeutic measures presents a certain danger —although less than surgery, for he does not believe that any fatalities can be imputed to it. It would be a miracle if it were entirely free from danger. He prefers for tardy ulcerative radiodermatitis dressings with physiologic serum or polyvalent serum, covering with sterile gauze, smearing the skin around with a camphor salve and changing the dressings as seldom as possible. If alternation of simple measures fail, the healing process might be activated by the high frequency current or cauterization with hot superheated air, or carbon dioxid snow, which destroys the nerve terminals and replaces the atonic wound with a simple wound, or, perhaps better yet, excision of the ulceration, with Thiersch flaps. He warns that the laboratory must be well ventilated and large to eliminate the production of secondary rays which form on surfaces too near the tube. When a radiologist shows signs of roentgen injury, he should abandon the work entirely as the tissues have acquired an extreme hypersensibility to the rays and a special tendency to anaphylaxis, an indirect anaphylaxis. He refers to a recent compilation of 104 cases of roentgen cancer on radiologists, and warns that the makers of protecting devices do not always make them perfect, so that the protection is illusory. At the same time, he adds, radiologists are too apt to forget themselves in their zeal.

Traumatic Spondylitis.—Cluzet's roentgenograms confirm his statement that fracture of vertebrae and minor injuries of the spine may be followed by a tardy spondylitis more or less remote from the site of the trauma. This posttraumatic spondylitis in the six cases described was characterized by pain in the lumbar region, limitation of the movements of the trunk, and bony excrescences on the lumbar vertebrae at a greater or less distance from the seat of the trauma. The osteophytes are more localized and the spondylosis less pronounced than is the case with rheumatic affections of the spine. In another case a beak-shaped osteophyte had developed on the femur, just above the internal condyle, after a bullet wound of the thigh far above. The pain did not develop until four years after the injury, and there is reason to assume that the osteophyte had not developed until this time, although this cannot be proved. In one of the cases described, the osteophytes developed under the observer's eyes, and the pains developed with them. The pains and the stiffness were effectually combated with physiotherapy, massage, manual mobilization, functional training and electric treatment. In future he would apply radiotherapy if it proves to be a fact that the formation of the osteophytes accompanies the development of the pains.

Radiology of Tuberculosis Suspects.—Delherm relates that among the 1,100 men suspected of tuberculosis and sent to his *centre de triage* for confirmation, 694 proved to be exempt from tuberculosis. Others have reported that 50 per cent. of the suspects proved to be nontuberculous. Roentgen examination often turned the scale, the radiograms taken not only of the whole lung but of the suspicious points. Especially important is stereoscopy taken erect, in the course of the same apnea. When the apex looks suspicious, he leaves it and examines other parts of the lung, having the patient cough and breathe deep. Then when he returns to the apex he often finds that it has cleared up. Some people never aerate the apex fully. When the bronchi cast wide, pronounced shadows, usually bilateral, the presumption is in favor of ordinary bronchitis; with tuberculosis, with such findings there would be other signs of it in the lungs. With cancer of the lung, the subjacent lobe is clear, and the outline of echinococcus cysts is usually roundish and well defined. He has encountered one case of syphilis of the lung; the signs of infiltration under the right clavicle and positive physical findings were not accompanied by bacilli in the sputum, and rapid improvement followed specific treatment. After pleurisy, the base may look veiled, owing to symphysis, and the movements of the diaphragm may be hampered by adhesions, and the lung look gray in parts. The clearing up of the lung during respiration and coughing and the absence of foci of congestion in the subclavicular region are instructive. In other cases, however, nothing but the continued absence of tubercle bacilli from the sputum will finally exclude tuberculosis.

Feb. 15, 1919, **9**, No. 7

*Why Wounds Do Not Heal. G. Milian.—p. 129.
*Neuritis from Ischemia. E. Duhot.—p. 135.
*Fermentation and Reduction in Bacteriologic Diagnosis. A. Besson, A. Ranque and G. Senez.—p. 140.

Wounds That Do Not Heal.—Milian analyzes the reasons why certain wounds drag along without healing. One of the principal reasons is the failure to recognize the cause preventing the healing. Syphilis may delay the consolidation of fractures and the healing of superficial wounds. Extragenital soft chancre often fails of recognition. He gives an illustration of a case of giant soft chancres on the fingers and hand which had long been futilely treated on a mistaken diagnosis. Wounds may be kept from healing, intentionally by the patient, and unintentionally by the surgeon's abuse of disinfectants. Even hydrogen dioxid may be incriminated in this respect. The antiseptics which prevent or check healing may irritate the skin around, and this artificial dermatitis is far from exceptional, but is usually attributed to everything but the right cause. To prevent intentional irritation of the wound, the simplest means is to apply a large roller dressing and draw straight lines with ink down the front and sides with numerous crossbars. Any attempt to unwind the dressing is betrayed at once by the irregularity of these lines afterward.

Neuritis from Ischemia.—Duhot says that time has confirmed the possibility of neuritis developing when the nourishment and oxygen have been shut off from the region, and waste products accumulate. The optic nerve may suffer from the ischemia after severe gastric hemorrhages, and severe polyneuritis may develop after excessive losses of blood otherwise. Peripheral neuritis is usually traceable to injury of the axillary or brachial artery, the femoral at the base of the triangle of Scarpa, or the popliteal. The neuritis due to ischemia from this cause is usually accompanied by paralysis of the terminal type of distribution, with reaction of degeneration and possibly tendency to sclerosis later. The anesthesia is of the segmental and centrifugal type, and there may be causalgia. There are also usually trophic and vasomotor disturbances. In prophylaxis the vessels must be spared as much as possible in operating, etc. Hemostasis must be secured without total compression of the vessel. The ligature must be applied on a sound stretch and at a point where the clot will not obstruct the collaterals. Ligation of the vein along with the artery has proved its superiority, as this maintains the balance in the circulation.

Fermentation and Reduction in Differentiation of Bacteria.—Besson and his co-workers have become convinced that the complete differentiation of bacteria requires study of their action on sugars in a fluid medium. They tabulate the findings in this respect with twelve different bacteria and five kinds of sugar and also with mannite, dulcite and glycerin. Their research indicates that the aerobic bacteria can be classified in three great groups: those that are inert to sugar and alcohols; those that attack them but without production of gas, and those which attack sugars and alcohols with generation of gas. These main groups can be subdivided according to the sugar attacked. Reduction of neutral red also differs when sugar or gelose is added to a medium containing neutral red, and this occurs in a characteristic way useful in differentiation. They have found very useful what they call the "diagnostic tube B." The medium is made with 1 liter of "beef water" (*eau de viande de bœuf*); 4 gm. glucose, and 3 c.c. of a 1 per cent. aqueous solution of neutral red. This mixture is distributed in test tubes, each containing an inverted hemolysis tube which serves for a fermentation bell. The tubes are sterilized at 110 C. and can be inoculated with a loop of the culture or one drop of a fluid medium. In eighteen or twenty-four hours in the incubator the tube will show whether there is any reduction of the neutral red, acidification or alkalinization of the medium, the production or nonproduction of gas, and the approximate amount, and the varying phenomena from anaerobiosis in the bell. This tube allows the bacteria involved to be recognized almost at a glance by the characteristic changes evident in the tube. With the colon bacillus for example, there is fluorescence and a yellow tint, while the bell is half full of gas. With typhoid and dysentery bacilli, the fluid is purplish and there is no gas production. The findings exclude at once a large number of germs which otherwise it would take long to eliminate.

Presse Médicale, Paris

Feb. 10, 1919, 27, No. 8

*Diagnosis of Amebic Liver Disease. P. Ravaut and Charpin.—p. 65.
*Chronic Enteritis in Soldiers. J. Carles.—p. 67.
*Influenza and Epilepsy. G. Maillard and Brune.—p. 70.
Jugulo-Carotid Aneurysms. P. Aumont.—p. 71.

Amebic Liver Disease.—Ravaut and Charpin state that in a large proportion of twenty-one recent cases of amebic hepatitis in soldiers there was nothing in the previous history to suggest amebiasis. Fully half of the men had never presented dysentery, had never been out of France, had had no fever before and the stools were normal and free from amebas in any form, and yet an exploratory puncture revealed amebas colonizing in the liver. It is possible, they suggest, that the ameba induces a different clinical picture in a temperate climate from that in the tropics. No other assumption will explain the facts here related. Be this as it may, amebic hepatitis should be thought of whenever a patient presents signs of hepatitis, usually febrile, with a distinct painful point. The suspicion of amebic hepatitis can be confirmed by exploratory puncture or by the success of medical treatment. They have been most successful with a combination of an arsphenamin preparation and emetin. Under this, soon the pain and fever subside and the liver becomes reduced in size and the general health improves to complete restitution. Two of the patients had been labeled tuberculous on account of concomitant congestion of the lung, and some had been under treatment for malaria. In a few weeks they witnessed an actual resurrection. In conclusion they warn physicians not to allow themselves to be surprised by amebiasis when this medical treatment will not only confirm the diagnosis but cure the patient as well. In a typical case reported the patient was given ten intravenous injections of 0.3 gm. of French neo-arsphenamin at six day intervals and eighteen injections of from 0.04 to 0.08 gm. of emetin—all in the course of forty days.

War Enteritis.—Carles describes eight different forms of chronic intestinal disease common in the soldiers returning from the different seats of war. Each requires special treatment, and he epitomizes the means for differential diagnosis and treatment. According to the special parasite involved the disturbances subside under emetin, sulphur, thymol, turpentine, or male fern. In exceptional cases the enteritis may be a sequel of paratyphoid or bacillary dysentery; the rectocolic ulcerations require local measures along with vaccine and serotherapy. Test meals will reveal a functional digestive insufficiency and suggest the treatment. The enteritis may be due to abnormal fermentation or be an actual intestinal neurosis, an "abdominal sympathosis," requiring prolonged local and general treatment.

Influenza and Epilepsy.—Maillard and Brune noticed in the service for epileptics at the Bicêtre hospice that no seizures occurred during the course of intercurrent influenza. The seizures returned as before after recovery from the influenza, but this inhibiting effect from the latter was striking and should encourage research along similar lines. They were impressed further by the exceptional gravity of the influenza among the epileptics; there were thirty-two deaths in the sixty-three cases; two other deaths could not be atributed directly to the influenza. They remark, *Les épileptiques sont des congestifs,* and hence a disease tending to induce further congestion is particularly serious for them. None of the inmates of the hospice who had influenza during the June epidemic contracted it anew during the October wave.

Feb. 13, 1919, 27, No. 9

*Leprosy at Marseilles. L. Perrin and G. Brac.—p. 77.
Examination of Vision of Aviators. A. Cantonnet.—p. 78.
*Anesthesia for Operations on Face and Neck. L. Dufourmentel.—p. 79.
*Autoserotherapy of Meningitis. J. Abadie and G. Laroche.—p. 82.

Leprosy in France.—Perrin and Brac examine for traces of leprosy all colonial troops arriving at Marseilles. They have been able to detect the disease thus in its very earliest manifestations. In some cases there was merely depigmentation of the skin at various points, giving the body a piebald aspect although the visible portions of the skin were apparently normal. One robust negro had one shoulder, the upper arm and half of the back form a white area in sharp contrast to the ebony skin around. Fifty men with incipient leprosy have been detected among the troops or working in factories, and have been repatriated. The leprosy had escaped detection when they entered the country. In some cases the only manifestations are a few tubercles, usually grouped in a circle on a zone of erythema; sometimes the lesion is scarcely larger than a silver quarter, and differentiation from syphilids and tuberculids is difficult. The increase in size of the ulnar nerve and the disturbances in sensibility confirm the diagnosis, but the sensibility may be variable and conflicting. Persistence of sensation does not exclude leprosy. Sometimes there is dissociate sensibility. One man with far advanced leprosy showed only large achromic patches on the body although the ulnar nerves were enlarged, with symptoms of neuritis in the arms, atrophy of groups of muscles and, finally, gangrene of the left leg. They warn in conclusion that persons even with the initial manifestations of leprosy are liable to spread the germs broadcast.

General Anesthesia for Operations on Face and Neck.—Dufourmentel concludes from his own experience and that of others that ether anesthesia by the rectum is the best method of anesthesia for children and for debilitated adults and for the tuberculous. It does not induce anesthesia in healthy adults as a rule. He insists that pure ether does not irritate the rectal mucosa, and hence there is no need to mix it with other substances. He uses about 2 c.c. of ether per kilogram injecting it through a Nélaton catheter of hard rubber, the catheter inserted for 10 or 15 c.c. It is then left in place, the outer end clamped, in order to facilitate evacuation of the ether at need. Inhalation of a few drops of ether or chloroform hastens and completes the anesthesia. The ideal anesthesia for operations on face and neck is by inhalation through a laryngotomy opening. His experience has confirmed more and more the advantages of this method.

Pyocyaneus Meningitis.—Abadie and Laroche cultivated the pyocyaneus from the spinal fluid of a young soldier with meningitis, and relate that they cured him by intraspinal injection of 3 c.c. of the patient's own serum, repeated thirteen days later.

Correspondenz-Blatt für Schweizer Aerzte, Basel

*Tuberculous Abscesses in Wall of Chest. H. Iselin.—p. 97.
*Chronic Nontuberculous Tendovaginitis. A. Vischer.—p. 103.
*Intranasal Removal of Lacrimal Sac. A. Affolter.—p. 115.

Tuberculous Abscesses in Chest Wall.—Iselin asserts, on the basis of his experience with 177 cases of tuberculous lesions in the chest wall, that it is not absolutely indispensable to resect the rib involved. This was the routine practice at the Basel clinic until the last few years have demonstrated that such lesions may retrogress under roentgen exposures. His prolonged study of his 177 cases has convinced him that the ribs are involved only secondarily. In 98 operative cases, sequesters or a probably primary bone lesion were found in only 6 cases, and the ribs were involved in only 3 of them, and in one of these the patient was a syphilitic. The fistulas ran in various directions, and the attempt to trace them to their source entailed the danger of opening the pleura. The success of roentgen treatment confirms further that the abscesses and fistulas are not connected with production of sequesters. Even the smallest sequester renders conservative treatment futile, but he has had 56 complete cures among the 77 cases in which systematic roentgen treatment was applied. In 16 of the 21 cases in which it failed, there were progressive tuberculous lesions in the lungs or elsewhere to which the patients succumbed. If the bone had been involved, roentgen treatment could not have cured 56 out of 77 cases with prompt and smooth recovery. In only 3 cases were the roentgen findings suspicious of primary tuberculosis. In 16 of 41 cases, there was a history of pleurisy, and in 14 of these cases the abscess in the chest wall developed after puncture of a pleural effusion, but not at the site of the puncture. The abscess was more of the nature of a gravity abscess, traceable to pleurisy, pericarditis or tuberculous glands. Tuberculous lymphangitis may set up multiple fistulas but the ribs are only exceptionally involved. Otherwise treatment should be conservative: aseptic puncture and evacuation, injection of iodoform or camphor and phenol, with roentgen exposures, heliotherapy, arsenic, iodin or inunctions. Not much can be anticipated from any treatment with a progressive pulmonary lesion in addition.

Nontuberculous Tendovaginitis.—Vischer remarks that the clinical picture interpreted as the result of stenosis from an inflammatory process in the tendon sheath has gradually obtained anatomic sanction and basis. The thickening of the wall of the tendon sheath narrows the lumen and binds the tendon, and the resulting disturbances demand operative relief. This is easily realized by simply slitting the tendon sheath. This puts an end to all trouble from this source. The thickening of the tendon sheath may be due to excessive functional demands, to rheumatism or to gout, or to a combination of these.

Intranasal Transseptal Dacryocystectomy.—Affolter shows in four illustrations how he obtains access through the nose to the lacrimal sac by resecting the lower portion of the septum, as for correction of deviation. The lacrimal sac is then easily reached with the instrument introduced into the opposite nostril and passed through the gap in the septum to the sac. A large number of patients have been operated on in this way, with complete success and without visible scar.

Policlinico, Rome

*Extinction of Focus of Trichinosis. G. Volpino.——p. 129.
*Postinfluenzal Immunity. D. Falcioni.—p. 133.
Antiserum Treatment of Tetanus. V. Grossi.—p. 139.
*Double Resection of Intestine. P. Pacchini.—p. 142.
Empyema with Expulsion of Scraps of Lung Tissue. P. Perazzi.—p. 144.

Rarity of Trichinosis in Italy.—Volpino relates that a hog with trichinae at Bergamo two years ago infected those who had eaten the meat, as also some dogs and rats, and a second hog was found infected at a point several miles distant. It had been previously affirmed that domestic animals in Italy were immune to trichinosis, and this focus of infection seemed to become spontaneously extinct in the region, as no animals, rats or dogs have shown any traces of trichinosis since.

Postinfluenzal Immunity.—Falcioni mentions among other significant happenings that a certain orphan asylum at Rome had escaped the epidemic of influenza until Jan. 2, 1919, when 100 of the 120 inmates developed the disease within three or four days. Of the twenty who showed no symptoms of it, sixteen had been recently orphaned by the death of their parents from influenza, and two others had had the disease at another asylum a few months before. Out of the entire 120 there were two who seemed to possess a natural immunity. There have been three waves of the epidemic at Rome, and each time it seemed to spare those who had had the disease before.

Double Resection of Intestine.—Pacchini operated twenty hours after a gunshot wound of the abdomen and found it necessary to resect two segments of the small intestine. A total of 1.5 meters was thus removed, requiring two entero-anastomoses. Notwithstanding the acute visceral peritonitis and lesions of mesenteric vessels, smooth recovery followed, the bowel functioning apparently regular, and the young man has regained his former weight.

*The Law of the Heart. A. Murri.—p. 1.
*Arrhythmia in Malta Fever. G. V. Ferralis.—p. 18.
Titration of Complement for Wassermann Test. B. Frattini.—p. 23.
*Typhoidal Hemiplegia. E. de Sarro.—p. 32.

The Law of the Heart.—This is the title of a recent work by E. S. Starling, and Murri recalls his own publications on this subject thirty-two years ago based exclusively on clinical findings, while Starling's work is based to a large extent on experimental research. Murri's findings were on abnormal hearts; he began therefore where Starling's law leaves off, at the limits of the normal. His experience therefore justifies amplifying Starling's law to the effect that while distention of the fibers of the sound myocardium increases the force of its contraction, with a diseased myocardium, however, the effect is to increase the number of insufficient contractions. He insists that the dilatation is the origin of the higher pulse rate, while Lewis and certain others regard the increased pulse rate as the origin of the dilatation. Murri quotes Pratt's article on "Digitalis Therapy," in The Journal, Aug. 24, 1918, saying that Pratt's conclusions confirm his own publications of twenty-one years ago.

Arrhythmia in Malta Fever.—The arrhythmia was of the complete sinusal type in the boy of 14 with Malta fever. The heart action became regular once more as he recovered.

Typhoidal Hemiplegia.—De Sarro's two patients were a young woman and a girl of 14 and both developed hemiplegia in the course of typhoid fever, on the right side in the girl, accompanied by aphasia. In the other the onset was with a convulsion, followed by hemiparesis and then hemiplegia but no signs of meningitis. The hemiplegia gradually retrogressed in the course of two months. In the girl the paralysis with contracture and the aphasia do not show much improvement to date. De Sarro compares with these two cases similar experiences from the literature. The sudden onset, the abrupt drop in the temperature, the aphasia, and the symptoms in general seem to point to an embolism in the left Sylvian region in the younger patient.

Riforma Medica, Naples

Jan. 25, 1919, **35**, No. 4

*Uremia. S. Livierato.—p. 65.
*Plastic Motor Operations. G. Vanghetti.—p. 71.

Uremia.—Livierato discusses the significance of azotemia for the diagnosis and the prognosis, as ascertained in sixty-three patients with various diseases. His findings are compared with those of others in this line. The highest degree of uremia was found always in the cases of nephritis. The six cases with the highest figure all terminated fatally; the range was from 0.86 to 1.90 per thousand in these cases. But one patient with chronic nephritis and 1.25 per thousand urea in the blood materially improved, and in some other cases of chronic nephritis the urea content of the blood was within normal range. The patients in this group all improved. The routine determination of the urea content of the blood revealed uremia in some cases in which, at the time, there was nothing otherwise to indicate retention of urea. This confirms Widal's statement that there is no absolute relation between the symptoms of azotemia and the degree of retention of urea. Livierato's fatal cases of nephritis with low uremia show that the prognosis may be grave even when the urea content of the blood is below that which is generally regarded as the limit of tolerance. This conflicts with Widal's classification of the cases as doomed to a fatal termination in a year with urea content of 1 or 2 gm., and within a few months or weeks with 2 or 3 gm. Livierato regards the outlook as grave with from 0.5 to 1 per thousand, but in his experience some of the patients in this class took a turn for the better, and some seem to have entirely recovered.

Plastic Motor Operations.—Vanghetti discusses this subject from the theoretic point of view and pleads for construction of artificial limbs "aiming at the greatest possible autarchy," as he expresses it, "not a pseudo-automatism." He suggests that it might be advisable to train cripples in a certain part of the work of making artificial limbs. What he calls "mixed cine-prostheses" seem to be the prostheses of the future, but it requires brains to design them and brains and study to adapt the amputation to this future function.

*Report on Pola Expedition. R. Paolucci.—p. 105.
*Pathogenesis of War Psychoneuroses. G. Pellacani.—p. 111.
Arthritism as an Infection. A. Ferrannini.—p. 116.
Differential Diagnosis of Appendicitis. T. Hernando.—p. 118.

Official Report of Naval Medical Officer.—This is the official report on the exploit in which the young navy surgeon, Paolucci, with one companion, harnessed a torpedo and rode it under harbor nets and through fields of mines and blew up the last of the five cruisers with which Austria entered the war. As some one said of the charge of the Light Brigade, *C'est magnifique mais ce n'est pas la guerre,* so the exploit of this medical hero of Pola *est magnifique mais ce n'est pas la médecine,* and consequently it cannot be given space in these columns.

War Psychoneuroses.—Pellacani insists that pithiatism, in Babinski's sense, forms part of hysteria, but that it is by no means all of hysteria, and this fact is particularly evident in war psychoneuroses as he explains. The essence of hysteria is the psychogenesis of the symptoms, and the essence of the psychogenesis is the susceptibility to suggestion. He emphasizes the necessity for drawing a sharp line of distinction between the emotional trauma, the emotive neurotraumatism with a neuropathic set of symptoms and a posttraumatic psychopathy, on the one hand and, on the other, the psychic factors (representative—emotional—suggestion—hysterogenous: psychogenesis) and the metatraumatic psychoneurotic set of symptoms. The two sets of symptoms may be associated, but the distinction between them is precise and essential, and it should be maintained to avoid continuous error and confusion.

*Echinococcus Cyst of Liver. E. Odriozola.—p. 159.
Borates in Waters of Arequipa District. M. A. Valesquez, E. Escomel and A. Maldonado.—p. 165.
Early Psychology in Peru. H. Valdizan. Cont'n.—p. 173.
*False Gallstone in Stomach. J. V. Bernales.—p. 196.
Psychanalysis. H. F. Delgado.—p. 202. Cont'n.

Echinococcus Disease of the Liver.—The first revealing symptom in Odriozola's case was jaundice coming on suddenly and intensely. There had been a few periods of malaise during the preceding months with vomiting and lassitude, and the onset of the jaundice was accompanied with transient intense pruritus. The jaundice had persisted for over two years, and the young man complained of oppression in the right hypochondrium, but there was no tendency to fever at any time and no pains to suggest gallstone mischief, although the stools were continuously clay colored. The absence of eosinophilia and the negative Wassermann reaction and absence of history of syphilis justified an exploratory laparotomy. This was done at the close of the third year, and a cystic tumor was disclosed on the concave aspect of the left lobe of the liver. The tumor was 15 by 9 cm. in diameter and 5 cm. thick, and its deep location rendered it extremely difficult to reach. The patient succumbed to hemorrhage in the depths the third day. The liver weighed 3,000 gm. and measured 36 by 24 and 8 cm. There had never been any pain from it, and nothing could be palpated that suggested a tumor. The jaundice was evidently due to compression of the bile duct by the tumor.

False Gallstone in the Stomach.—Bernales' patient was a man of 40 who for two years had been having acute pain at times in the stomach at intervals of four or five days, with no connection with the food. Each attack was accompanied with eructation and vomiting, with sometimes traces of blood. Giving up all work after five months of these attacks banished them completely during the eight months of rest, but the pains returned as severe as ever when he returned to his work as a miner. The attacks became more severe and returned daily, the pain always located in the stomach or radiating to the left hypochondrium, and it did not yield even to morphin. The stomach was opened and a calculus was removed which seemed to be a gallstone, about 2½ inches by 1½ wide, shaped like a potato. This calculus was formed of a clot of blood, almost organized, coated with bile pigments.

*Action of Tuberculin on the Blood. F. Mas y Magro.—p. 1.
Defensive Ferments in Tuberculin Treatment. R. Dargallo.—p. 79.
*Mitral Stenosis and Pulmonary Tuberculosis. J. V. Montenegro.—p. 89.
Diffuse Tuberculous Cellulitis. A. C. Lladó.—p. 97.
*Roentgen Findings in Tuberculous Lung. L. Sayé.—p. 105.

Importance of Color Index and Differential Blood Count as Guide for Tuberculin Treatment.—Mas y Magro's extensive study of the influence of tuberculin on the blood and blood-producing organs is the first article in this handsome new journal which herewith enters the scientific arena. It is to be published three times a year, with possibly supplements at shorter intervals, the whole to form a volume of about 600 pages. The annual subscription is 30 pesetas, about $6, and Dr. L. Sayé, Aragon 282, Barcelona, is the editor.

Mas y Magro reports that tuberculin modifies constantly and profoundly the blood and blood-producing organs. These modifications pass through three phases, the blood first tolerating, then showing signs of saturation, and then, finally, of toxic action. Each of these phases can be readily estimated from the color index and the differential blood count, as he explains in detail. The febrile reaction occurs only when the stage of saturation or toxic action is reached. The differential blood count and the color index will thus enable us to guide tuberculin treatment so as to keep it just short of inducing the harmful febrile reaction. His research was done on twenty-two guinea-pigs besides extensive clinical experiences. The differential counts day after day are given and the histologic findings in the animals at different intervals. The constancy of what he calls the basogranular reaction after the first injection of tuberculin was *striking* in all the animals and in the four healthy adults tested, in twelve afebrile tuberculous patients, and in three febrile patients with leukocytosis. This reaction indicates, he reiterates, a toxic influence on the blood-producing apparatus from the very first and with remarkable promptness. In all his investigations of the action of different substances on this apparatus, he has never found one so prompt and constant in its action as tuberculin. It is not surpassed even by lead and, much less, by molybdic acid.

When the tuberculin is well tolerated the color index declines. In the saturation phase it keeps stationary, and it runs up in the toxic phase. When the stationary color index denotes that the stage of saturation has been reached, a very minute dose of tuberculin will suffice to transform it into the toxic phase. The curve of the color index, taken twenty-four hours after the therapeutic dose, will thus serve as a guide for the next dose, and we can thus ward off any febrile reaction. When the injections are continued after the blood findings show that the toxic stage has been reached, symptoms of a general toxic order soon become apparent, loss of appetite and weight, prostration, etc. The color index alone seems to be a most exact and sensitive guide for tuberculin treatment, while it does not require much technical skill to divide the percentage of hemoglobin by the percentage of red cells as compared with the recognized normal, namely, 5,000,000, to determine the color index.

Mitral Stenosis and Pulmonary Tuberculosis.—Montenegro relates that in his 20,000 cases of pulmonary tuberculosis he encountered only one case in which active pulmonary tuberculous lesions were accompanied by mitral stenosis. This is a proportion of only 0.005 per cent. and justifies the general assumption that mitral stenosis is an obstacle to the development of pulmonary tuberculosis. Even this one case in his experience tends to prove this because the pulmonary lesions kept mild even during the woman's two pregnancies. He adds that this was the only patient with pulmonary tuberculosis among his 300 cases of mitral stenosis. It formed thus 0.3 per cent.

Roentgen Findings in Pulmonary Tuberculosis.—Sayé gives five fine roentgen plates and interprets the findings in twenty-five cases. He follows this with a study of the anatomy and clinical findings with pulmonary tuberculosis in general, comparing the four great types, the cheesy, the fibrous, the fibrocheesy and the miliary, and their findings, the heredity with each, the initial and later symptoms, the roentgen findings in different phases, the complications and duration. He appends thirteen solidly printed pages of bibliography on various phases of phthisiology published in the last two years.

Brazil-Medico, Rio de Janeiro

Dec. 28, 1918, **32**, No. 52

*Myxosporidia in Brazilian Fishes. A. M. Da Cunha and O. Da Fonseca.—p. 414. Cont'n.
*Chart for Recording Gynecologic Data. J. Adeodato.—p. 414.

Myxosporidia in Brazil.—Da Cunha and Da Fonseca have been publishing each week descriptions of new species derived from Brazilian fishes.

Palpation of the Vagina.—Adeodato gives an illustration of a diagram in the form of a circle barred off like a compass into eight portions on which he records the findings of palpation of the vagina and internal genitals. Each division corresponds to some part of the field under examination: To the north, the bladder, the anterior surface of the uterus and the cervix; to the south the pouch of Douglas and the rectum; to the west the parametrium and the right tube; the right ovary to the southwest; to the northwest the right round ligament. Recording the data by this means shows the relation between the findings, impresses them on the memory, and has proved extremely useful in his experience.

*Antibodies in Leukocytes of Immunized Animals. A. Bachmann.—p. 549.
History of Public Hygiene in Argentina. E. R. Coni.—p. 574, Cont'n.
*Postoperative Obliteration of Mesenteric Vessels. P. Escudero.—p. 625.
*Tracheobronchial Glandular Disease in Children. J. P. Garrahan and O. S. Dastugue.—p. 643.
*Cyst in Lower Jaw. J. M. Jorge (h.) and J. Layera.—p. 662.
Tuberculosis. J. J. Vitón.—p. 690. Cont'n.

Immunization to Infections.—Bachmann expatiates on the highly important specific property acquired by the leukocytes in the course of an infection or inherited. This property is not much modified even by the death of the leukocytes; it is possible to immunize small animals with the killed immune leukocytes, but larger quantities are required than with the living leukocytes. The plasma alone does not have this immunizing action. The specific property possessed by the leukocytes does not pass into the serum at the moment of coagulation, but it can be obtained in the serum by treating the leukocytes with congelation, according to Buchner's technic, thus transforming the fluid in which the cells are suspended into a preventive antiserum. By this means we practically isolate the substance which confers the immunizing property on animals and man. Bachmann explains that it is found exclusively in the polynuclears of immunized individuals, and it saves others from infection with spontaneous or induced infection. These specific substances have been called leucines and endolysins, and he has found them effectual not only in immunizing guinea-pigs against infection from microbes injected intraperitoneally but also in aiding to cure already established infection. By heating the well diluted endolysins to 75 C. in the presence of a little gelatin, the common bactericidal properties of the leukocytes were destroyed while the specific immunizing property did not seem to be impaired. Small animals injected with the leukocyte immune products, one hour after inoculation with the infectious germs, all survived, while all died of those injected merely with ordinary leukocytes or plasma or both; the infection running the usual course as in the controls. Bachmann reiterates that his success in getting rid of the bactericidal element of the endolysins leaves the specific immunizing substances free to exert their action. Their constitution seems to be analogous to that of the antibodies in the serum, but it seems to be a more stable specific element than the serum antibodies, and this has permitted its isolation. The research was done mainly with anthrax, but the results were confirmed with typhoid infection. He reiterates that these facts complete the cycle of transformation undergone by the leukocytes in acquired immunity. His article is in French.

Postoperative Obliteration of Mesenteric Vessels.—Escudero has found records of 360 cases of postoperative thrombosis of the mesenteric vessels up to the year 1913. The correct diagnosis has been made only in thirteen of the total 360 cases. In his own experience with three cases the mesenteric thrombosis proved fatal in two within three days after an operation for chronic appendicitis or adhesive perienteritis. In the third case there was an interval of a month after the laparotomy for acute appendicitis before the thrombosis developed and proved fatal in two days. The diagnosis wavered between acute hemorrhagic pancreatitis and mesenteric thrombosis, but the operation twenty hours after the first symptoms confirmed the latter; ascending venous thrombosis from the primary focus was evidently responsible. In the two other cases the vessels showed signs of syphilitic changes, confirming the frequency of syphilis as a factor in postoperative mesenteric thrombosis. The vessels are already so pathologic that even the slightest superposed element is sufficient to induce the thrombosis. The clinical picture may include intense pain, rebellious to morphin, tympanites around the umbilicus, developing about six hours after the operation, profuse gastric hemorrhage, pulse up to 120 or 160, with cyanosis, restlessness and insomnia, all developing within twenty-four hours. Another laparotomy is the only means of salvation, and this only when done in time and the lesions are not already irreparable.

Diagnosis of Tracheobronchial Glandular Disease in Children.—Garrahan and Dastugue found the tuberculin reaction positive in 79 of 115 children suspected of tuberculosis, the proportion increasing regularly from 48 per cent. between 2 and 6 to 95 per cent. between 11 and 13. In a number of the children presenting pronounced physical signs, there was nothing in the roentgen picture to suggest glandular involvement. On the other hand, some of the children free from physical signs of tuberculosis showed distinct roentgen findings with enlarged glands. The tuberculin reaction also did not always correspond with the roentgen and physical findings. In 41 children with little or no signs of glandular involvement, the tuberculin reaction was positive in 39 per cent. as also in 85 per cent. of the 74 with evidences of tracheobronchial glandular disease. These experiences confirm the inadequacy of percussion and auscultation in detecting tracheobronchial glandular disease.

Cyst in Lower Jaw.—Jorge and Layera remark that the rapid and complete recovery in the case of dentiferous cyst reported confirms the advantages of the technic applied. The patient was a man of 37 and the outer wall of the cyst was respected. They merely opened up the cyst widely and kept it open for forty-eight hours. The cavity was then tamponed after touching the walls with tincture of iodin. In forty-eight hours the tampon was removed, the cavity was rinsed out repeatedly with a mild antiseptic, and the patient kept on fluid food for two weeks. The bone has regenerated during the months since, aided by the refraining from resection of the wall.

Revista de Medicina y Cirugia, Havana

Jan. 25, 1919, **24**, No. 2

*The Pandemic of Influenza. M. R. Casabó.—p. 29.
*Anti-Influenza Bacterin. A. Recio.—p. 35.
*Post Influenzal Amblyopia. A. F. Oñate.—p. 53.
*Tardy Hemorrhage after Removal of Adenoids. H. Seguí.—p. 55.

Influenza.—Casabó reports encouraging success in treatment of influenza with a vaccine made from the sputa and secretions in some grave cases of influenza. With the germs thus derived, a vaccine and a bacterin were prepared, and in thousands of applications he never heard of a mishap.

Recio describes the technic by which this polyvalent, mixed anti-influenza bacterin was made. Agar with human blood was the culture medium, and as the microbes are used as primarily developed, there is greater chance, he says, that the bacterin contains the unknown virus responsible for the influenza than those prepared by other technics. They have distributed 10,000 doses (four ampules each), and have had most favorable reports of its prophylactic action. In one group of 300 persons thus vaccinated only five developed influenza and two of these had had only one and the other two doses, instead of the routine four. In the two other cases the influenza developed six weeks after the vaccination but ran a very mild course. None of 100 children thus vaccinated at the height of the exceptionally severe epidemic at Camagüey contracted the disease.

Postinfluenzal Amblyopia.—Oñate's two patients who developed amblyopia after influenza were a dentist and a merchant of 65. The influenza in the first mentioned was of severe gastro-intestinal type, in the other of the pneumonia type. The ophthalmoscopic findings and the urine were normal in both, and the progressive amblyopia was evidently of toxic origin. Oñate ordered the first patient to refrain from meat, taking mostly milk and purées of vegetables, with Bulgarian bacilli and a mild laxative. Under a week of this, vision in one eye returned to normal, and by the end of the second week also in the other eye. The man had been having an intense urticaria with the amblyopia, and this subsided with it. In the second case the same treatment was given, with sodium iodid internally in addition, with equally prompt success.

Severe Hemorrhage After Removal of Adenoids.—Seguí's case teaches the necessity for repose after an operation on the throat. Only the most urgent measures, packing the entire cavity, succeeded in arresting the severe hemorrhage which had already induced a syncopal condition. After the adenoids had been removed, the mother was told to take the boy of 12 home in her automobile and put him to bed, or at least make him lie down. But instead of this the pair went shopping, and the alarming hemorrhage came on the third hour. Seguí refers also to a similar tardy hemorrhage in an adult after removal of relics of adenoids. All warn of the necessity for keeping in bed for twenty-four hours at least after any operation on the throat. In none of the cases was there any suspicion of hemophilia.

Semana Medica, Buenos Aires

*Syphilitic Sterility and Amenorrhea. G. Giacobini.—p. **14**.
School Lunches. E. R. Coni.—p. 16.
State Care of the Hospitals and the Public Health Service in Latin American Cities. I. Colombia. C. Solano R. (Bogotá).—p. 19.

The Islands of Langerhans.—García declares that the islands form part of the internal secretion system. The pancreas thus has two cycles of secretion, an internal and an external. Comparative anatomy and embryology confirm this view, and show further that the acini and the islands of Langerhans become reversible in time. There is much to sustain the assumption, he says, that the secretion of these islands is what controls the metabolism of sugar.

Syphilitic Amenorrhea.—Giacobini cites some cases from his experience which confirm that syphilis alone may be responsible not only for sterility but for amenorrhea and the premature menopause.

Nederlandsch Tijdschrift v. Geneeskunde, Amsterdam

Jan. 4, 1919, **1**, No. 1

*Herman Boerhaave, 1668-1738. E. C. van Leersum.—p. 1; —p. 85; —p. 100.
Boerhaave as Man and Chemist. E. Cohen.—p. 13.

Portraits of Boerhaave. J. P. K. de Zwaan and others.—p. 77.
Boerhaave and the University. J. E. Kroon.—p. 87.

Boerhaave.—The entire issue of the *Tijdschrift* is devoted to this great physician of the seventeenth century in memory of his birth, 250 years ago, Dec. 31, 1668. A number of illustrations accompany the different articles, with reproductions of letters and other documents, including Van Swieten's shorthand notes of Boerhaave's lectures. Van Leersum has been studying these notes for years and gives the transcription of them. The lectures were in Latin and the notes cover a period of several years, including the latest lectures. An exhibition of Boerhaaviana was held at Leyden and the anniversary was formally celebrated with much ceremony.

Jan. 11, 1919, **1**, No. 2

*Pathogenesis of Gastric Ulcer. C. D. de Langen.—p. 178.
*Influenza. E. Bemelmans.—p. 184; A. Cijfer.—p. 187.
Diagnosis of Acute Appendicitis. A. Van Balen.—p. 188.

Pathogenesis of Gastric Ulcer.—De Langen discusses gastric ulcer from the standpoint of clinical medicine, emphasizing its extreme rarity among the natives of Java. It seems to be rare also in Japan. Examination of the stomach findings in thirty-five persons at Batavia, healthy or with malaria or other disease, failed to show any deviation from the normal figures in respect to acidity. On the other hand, the predominance of sympathecotony in the tropics and the absence of vagotony confirm the theory that vagotony is the main factor in gastric ulcer, and that the rarity of vagotony in the tropics is responsible for the rarity of gastric ulcer. De Langen's research on the higher tonus in the sympathetic nervous system in the tropics was summarized in these columns, Oct. 26, 1918, p. 1447. The facts observed apparently confirm the vagotonic origin of gastric ulcer.

Influenza.—Bemelmans says that the success of arsphenamin in curing contagious pleuropneumonia in horses justifies its use in influenza. The disease in man and in the horse seems to be etiologically, bacteriologically and epidemiologically identical he declares. Arsphenamin has been used on a large scale for pleuropneumonia in horses during the war, he says, "striking quick and striking hard." A single intravenous injection seemed to save the horse. Alexander has recently reported that he has never seen influenza develop in persons who have recently been given some arsphenamin preparation. In conclusion, Bemelmans cites some writers who have reported benefit from arsphenamin in scarlet fever, typhus, eczema, and adenitis in horses and in pneumococcus infection. For horses, it has been found that the exact dose is extremely important. Bemelmans declares that the proper dose, given as soon as there are signs of serious complications in lungs or elsewhere, would undoubtedly have as favorable an action in man as in the horse.

THE COMPLEMENT FIXATION TEST IN THE DIAGNOSIS OF TUBERCULOSIS

A CLINICAL AND LABORATORY STUDY *

HENRY F. STOLL, M.D. (Hartford, Conn.)
Major, M. C., U. S. Army; Chief of the Tuberculosis Division, Walter Reed General Hospital, and Instructor in the Diagnosis of Tuberculosis, Army Medical School

AND

LESTER NEUMAN, M.D.
First Lieutenant, M. C., U. S. Army; Serologist, Walter Reed General Hospital

WASHINGTON, D. C.

Not all of the reports on the complement fixation test in the diagnosis of tuberculosis have recorded the high degree of accuracy that Craig[1] and Miller[2] ascribe to it. This is in large part due to the fact that the method of performing the test has not as yet been standardized. But even with a uniform technic, the results of different observers would not have the same high percentage of agreement with the clinical diagnosis as obtains with the Wassermann test in syphilis. This is due to the many difficulties that beset the clinician in classifying his tuberculosis patients. The man whose diagnostic zeal is greater than his experience will detect tuberculosis where none exists, and even those of large experience differ as to when a case should be termed "arrested" and when "cured." No more puzzling problem confronts the internist than to decide whether there is any relation between the vague toxic symptoms that a patient presents and the old and apparently healed tuberculosis which the examination reveals. It is in such cases that the clinician looks to the laboratory for help. Will the complement fixation test as now performed fill the want?

At this time it does not seem necessary to us to review completely the literature, as this has recently been well done by Moon,[3] von Wedel,[4] and Stivelman.[5] Therefore, aside from a summary of the subject, only those articles which have appeared since these reviews will be discussed in any detail.

The first investigators to use the complement fixation test for the diagnosis of tuberculosis appear to have been Widal and LeSourd,[6] followed by Bordet and Gengou,[7] Wassermann and Bruck,[8] Caulfield,[9] Laird,[10] Hammer,[11] Calmette,[12] and a host of others, with varying success.

Miller,[2] using a bacillary emulsion as an antigen, reports nearly 100 per cent. positive results in active cases of tuberculosis, and 100 per cent. negative results in known nontuberculous cases. Craig,[1] using an alcoholic extract of tubercle bacilli, found 92.6 per cent. positive complement fixations in active cases, and 66.1 per cent. positive in inactive cases. In 150 cases with a positive Wassermann test and no demonstrable lesion in the lung, the reaction was negative. One hundred cases of diseases other than syphilis and tuberculosis were all negative. He regards the test as one of established reliability. Burns, Slack, Castleman and Bailey[13] obtained similar favorable results.

Opposed to such favorable reports is the work of Corper[14] and Corper and Sweany,[15] whose results were not constant and who found many cross fixations with positive Wassermann serums.

Wilson[16] emphasizes the importance of examining each guinea-pig serum for its complement value and especially its fixability with tuberculosis antigen and tuberculous serum. This is recommended even in a pooled complement. A lipoid-free bacillary antigen is also described in which the tubercle bacilli are grown on glycerin broth, the cultures filtered, and the lipoids extracted from the organisms recovered from the filtration with alcohol and ether. The dried organisms are then emulsified in salt solution. This is a preliminary report on technic and does not include any case reports.

Von Wedel,[4] using the Wilson antigen, reports a very successful series of cases. He makes the interesting observation that many serums from known tuberculous cases show a negative reaction immediately after bleeding, but if kept in the refrigerator five or six days under sterile conditions, they become positive. He states that this does not occur in known nontuberculous cases. He obtained 100 per cent. negative results in known nontuberculous cases, nearly 100 per cent. positive results in primary and active tuberculous cases, and 25 per cent. positive results in the partially active and inactive cases. As for moribund patients, the showing was usually negative. He emphasizes the importance of pooling the serum of at least six guinea-

pigs as complement or the testing of the complement value and fixability of a single animal.

Moon[3] reports a series of cases in which he used a bacillary emulsion antigen prepared from dried bacilli. He states, however, that since compiling this report he has used a fresh, virulent bacillary antigen with much greater success. With the dried antigen, in 156 tuberculous cases, 85.2 per cent. were positive. Of these, twenty-one cases of incipient tuberculosis were positive in 87.5 per cent.; forty-nine cases of moderately advanced tuberculosis were positive in 85.7 per cent., and eighty-three cases of far advanced tuberculosis were positive in 84.3 per cent. Forty per cent. of sixty-one cases of suspected tuberculosis were positive. Twenty-six cases of other diseases showed 26 per cent. positive results. Of 100 positive Wassermann serums, thirty-eight gave a positive reaction. There were twelve positive tests among 100 young, healthy adults. Two of these were found to be tuberculous. He believes the test to be one of known clinical value, and as valuable in tuberculosis as the Wassermann reaction in the diagnosis of syphilis.

Petroff[17] describes a new glycerin extract tubercle bacillus antigen, for which he claims simplicity of preparation and reliability.

Brown and Petroff[18] found positive reactions in 51 per cent. of the incipient cases of tuberculosis, 73 per cent. positive in the moderately advanced cases, and 81 per cent. of the far advanced cases. They believe that as a case advances it becomes more active clinically and serologically. In 139 cases with positive sputum, 90 per cent. showed a positive complement fixation test, and when activity was also present, the positive results were 98 per cent. Cases with blood spitting were much more likely to be positive than those without. They do not believe that the presence of a positive Wassermann reaction has any bearing on the complement fixation for tuberculosis. They state that a positive reaction indicates that an antibody is, or has been, circulating in the blood stream. The intradermic test was found to be more sensitive than the complement fixation. They place the reaction among the tests of known clinical value.

Lange,[19] using four different antigens, namely, the bacillary emulsion of Miller, a sodium hydroxid extract, a methyl alcohol extract and the potato broth culture filtrate of Petroff, examined 864 serums. Fixation of some degree was found in 51.5 per cent. of the tuberculous cases, while nontuberculous cases were positive in 13.6 per cent. The alcoholic antigen gave the highest proportion of strong fixations in the clinically tuberculous cases, and the sodium hydroxid antigen, the lowest. With nontuberculous cases, the greatest proportion of strong fixations was obtained with the sodium hydroxid antigen, the smallest with the potato broth filtrate antigen. Of 147 positive Wassermann serums, twenty-six, or 18.7 per cent., were positive. Four of these were clinically tuberculous.

Stivelman[5] reports a series of 205 cases, twenty-two of which were nontuberculous, using Miller's antigen. The Wassermann reaction done as a routine showed four positive reactions, though none of the latter could be diagnosed as syphilitic. He found that about 50 per cent. of the tuberculous cases, active and inactive, gave a positive fixation. Seventy-four per cent. of twenty-five inactive cases with positive sputum gave a complement fixation, whereas only 28 per cent. of twenty-five active cases with negative sputum gave a positive reaction. Inactive cases with negative sputum gave 41 per cent. positive tests, while in active cases with negative sputum a positive reaction was obtained only in 28 per cent. He was particularly impressed with the exceedingly low proportion of incipient cases giving a positive fixation, the active being 15.8 per cent. and the inactive 39.5 per cent. He was unable to corroborate the favorable report of Miller.

A complement fixation test was made in over 100 cases that were referred to the tuberculosis section of the medical service of the Walter Reed General Hospital, for known or suspected tuberculosis. A few patients were seen only once. The others were examined several times, and most of them were in the wards for varying periods of observation. All patients about whom these was any question as to diagnosis were examined by two or more qualified medical officers and, with very few exceptions, stereoroentgenograms were taken after the examination was made. A stereoscope in the ward made possible an intimate study of the patient and his roentgenogram.

Depending on the symptoms, physical signs and roentgenoscopic findings, the cases were classified into six groups:

1. Signs of small healed lesion present (usually apical). Tubercle bacilli not demonstrated, (*a*) symptoms absent or due to some other cause, and (*b*) symptoms suggestive but inconclusive.
2. Small lesion; signs suggesting activity. Symptoms definite (tubercle bacilli may or may not be present).
3. (*a*) Large lesion; parts of one or more lobes involved; symptoms few or absent, and (*b*) same lesion as in 3 *a*, but symptoms of activity. Prognosis for arrest, good.
4. Extensive lesions and complications. Prognosis poor.
5. Possibly tuberculous; (*a*) inconclusive signs, suspicious symptoms, and (*b*) signs of small healed lesions; symptoms suggestive but inconclusive (Group 1 *a*).
6. Nontuberculous cases.

The percentages given should be accepted with some reservation because of the small number of cases in certain groups.

Group 1 *a* (seventeen cases) comprises those that showed evidence of an old and apparently healed tuberculous lesion and was made up of three classes of cases: (1) those who had one or more symptoms suggestive of tuberculosis but in whom a careful study demonstrated some other cause; (2) those presenting the residue of some acute pulmonary infection which bore no relation to the old tuberculous process, and (3) a small group with no symptoms but whose physical signs had excited suspicion. In this group, the diagnosis of which was given as "no sign of active tuberculosis," the complement fixation test was positive in 6 per cent.

The necessity for the second subdivision of this group, which may be designated as having "signs pointing to an old lesion with ill defined symptoms possibly due to tuberculosis," will be questioned by those who experience little difficulty in classifying their cases. We have not infrequently been in serious

18. Brown, L., and Petroff, S. A.: Am. Rev. Tuberc. 2: 525-540, 1918.
19. Lange, L. B.: Am. Rev. Tuberc. 2: 541-545, 1918.

doubt as to whether or not certain symptoms were due to a lesion when activity could not be established either by physical signs or by roentgenoscopic studies. This group of eleven gave 18 per cent. positive reactions.

The number of really incipient cases (Group 2) is unfortunately small, as it is in this group, in which tubercle bacilli are so often not to be found, that we most need the assistance of the complement fixation test. Our cases were so few—only eight in all—that no deductions of value can be drawn. Thirty-seven per cent. gave a positive reaction. Some of the more advanced cases studied seem to show that the incipient stage may sometimes merge into a moderately advanced stage with no symptoms to herald its progress. We are inclined to believe that some of the cases that were ultimately diagnosed as not clinically tuberculous would have been called incipient had opportunity not been afforded for careful study including stereoroentgenoscopic examination. Moreover, in a few instances, the roentgen ray revealed that our apparently incipient case was in reality moderately advanced. Two of four moderately advanced cases, with few or no symptoms, reacted positively.

TABLE 1.—RESULTS IN ACTIVE, INACTIVE AND POSSIBLY ACTIVE CASES

	No. of Cases	Per Cent. Positive
Total active cases of tuberculosis	36	58
A. Tubercle bacilli in sputum	27	67
B. Without tubercle bacilli in sputum	9	33
Possibly active tuberculosis	19	16
Evidence of old inactive lesion	17	6

The number of moderately advanced cases with symptoms of activity, yet presenting a good prognosis, was seventeen, and 65 per cent. gave a positive test. In fifteen, there were tubercle bacilli in the sputum, and of these 62 per cent. gave a positive reaction. Eleven cases classified as actively progressing, with a poor prognosis, gave 64 per cent. positive. In all but one of this group the sputum was positive. In this case bacilli were abundant in the bronchial secretions at necropsy. Of the group "possibly tuberculous," those having signs of an old healed lesion have already been considered (Group 1 *b*). There were eight other patients in whom the evidence of an old lesion was lacking, but who had a suspicious yet inconclusive history. Among these were several cases of serous pleuritis, some of which were probably tuberculous. This group as a whole gave 15 per cent. positive reaction. In fifty-one patients the physical signs did not indicate an old tuberculous lesion, and their symptoms were due to other causes. The reaction was positive in 10 per cent. For practical purposes we may add to this group those who had an old healed process but no activity, making a total of sixty-eight patients suffering from various conditions, clinically free from tuberculosis, with 8 per cent. giving a positive fixation test.

The serums from forty individuals, especially selected because of their very robust condition, were examined and, with the exception of one case, all were negative. This case showed a "single plus" reaction (50 per cent. inhibition). However, when the test was repeated several times on fresh serum, it was found constantly negative.

The complement fixation for tuberculosis was done on 228 different serums, showing a positive Wassermann reaction. The Wassermann reactions were made with a human hemolytic system and a cholesterinized human heart antigen. In this series, 486 examinations were made, as a number were repeated several times. Eleven of these serums showed a positive fixation for tuberculosis. Three of these patients were found to be tuberculous, the other cases apparently being nontuberculous. The latter may belong to the group of cases, described by Brown,[18] in which the test remains positive after a cessation of activity.

TECHNIC

Serum.—The patient's serum is removed from the clot as soon as possible. It is inactivated for thirty minutes at 56 C. One-tenth c.c. undiluted serum is used for the test and 0.15 c.c. as a control for anticomplementary action. When used again, the serum is again inactivated for ten minutes at 56 C.

Antigen.—The lipoid-free tubercle bacillus antigen described by Wilson[16] was used. The amount of antigen used for each test contained approximately 10,000 dried tubercle bacilli. It was never anticomplementary in four times the amount used in the test. Before each test, the amount of antigen used was diluted and inactivated at 56 C. for thirty minutes.

Complement.—The pooled serum from at least six guinea-pigs was always used in a 1 : 10 dilution. After titration with sensitized cells, two units are used in the test.

Hemolytic System.—One-tenth c.c. of 5 per cent. washed sheep corpuscles is used, sensitized with an equal amount of diluted amboceptor containing two standard units. Sensitization is done in the water for thirty minutes at 37.5 C.

Controls.—Controls are run on the antigen for anticomplementary action and specificity, on the serum for anticomplementary action and specificity, on the complement for stability (system control), and on the sensitized cells for reading control.

The complement titration and the test are incubated in the water-bath at 37.5 C. for fifteen minutes, and the fixation for one hour.

TABLE 2.—RESULTS IN THE NONTUBERCULOUS

	No. of Cases	Per Cent. Positive
Symptoms or signs of pulmonary disease, but diagnosed as not tuberculous	51	10*
Especially robust individuals	40	0
Nontuberculous syphilitics	225	3.5

* Two cases which at first gave a positive result, but later a negative, not included.

While stationed at this post, Lieut. H. von Wedel inaugurated successfully the complement fixation test for tuberculosis in the routine of the laboratory. A few of the cases reported in this series were examined by him. However, we are not convinced that his observation regarding the difference in reaction of a fresh serum and one kept from five to seven days is diagnostically correct. He believes that many serums from tuberculous cases which are negative on the day following the taking of the blood become positive when kept in the refrigerator for from five to seven days under sterile conditions. Rapoport[20] made a similar observation in his study of the fixation test in influenzal pneumonias, using strains of *B. influenzae* as antigen. Of all serums in this series that were examined, the examinations were made on the day following bleeding and again one week later. However, we have recorded only the first result in our statistics in this paper, reserving the results of the second examination until such time as we are convinced of the real value of von Wedel's observation.

---

[20] Rapoport, F. H.: The Complement Fixation Test in Influenzal Pneumonia, J. A. M. A. **72**: 633 (March 1) 1919.

A Wassermann test with a cholesterinized antigen has been made in all of the cases. We cannot agree with those who assert that tuberculosis will give a positive reaction in the absence of syphilis if a cholesterinized antigen is used. Too often the failure to obtain a history of infection or evidence of syphilitic disease is considered sufficient evidence to exclude syphilis. Seven per cent. of our forty-one definite cases of tuberculosis gave a positive Wassermann reaction, and all gave a history of a venereal sore.

SUMMARY

1. Forty robust men of the surgical service all gave a negative fixation test.
2. Sixty-eight individuals, when first seen, presented some symptoms, or physical signs, suggesting tuberculosis, yet were ultimately diagnosed as not clinically tuberculous. The tuberculous fixation test was negative in 92 per cent. of this group.
3. Of nineteen patients about whom a reasonable doubt existed and who were classified as "possibly tuberculous," 15 per cent. gave a positive reaction.
4. Of eight incipient cases, 37 per cent. gave positive reactions.
5. Four with moderately advanced lesion, yet few or no symptoms, gave 50 per cent positive.
6. Of seventeen patients with moderately advanced disease and definite symptoms of activity, but in whom the prognosis seemed good, 65 per cent. were positive.
7. Of eleven with advanced disease and a poor prognosis, 64 per cent. were positive.
8. Of twenty-seven active cases with tubercle bacilli in the sputum, 67 per cent. were positive.
9. Of nine active cases without tubercle bacilli in the sputum, 33 per cent were positive.

CONCLUSIONS

1. It is at once apparent that the practical utility of the complement fixation test in the diagnosis of tuberculosis is limited by the fact that the highest percentage of results obtains in the cases in which its need is least felt, namely, the obvious cases with tubercle bacilli in the sputum.
2. Nevertheless, from our experience, it would seem that with suspicious symptoms and suggestive, yet inclusive signs, a negative fixation test, using the method herein described, increases to a considerable degree the probability of the nontuberculous nature of a given case.
3. With the same symptoms and signs, a persistently positive reaction probably signifies an active tuberculosis.
4. A positive reaction occurring with neither symptoms nor signs does not justify a diagnosis of active tuberculosis, though it is quite probable that there has been an active process recently. In such a case, roentgenoscopy should be employed and the patient observed for several months.
5. With frank signs and symptoms, yet with no tubercle bacilli in the sputum, a negative test cannot outweigh the clinical evidence, though in all such cases a Wassermann test should be made.
6. The diagnosis of tuberculosis is many times one of great difficulty. A careful history, a thorough examination, repeated sputum examinations and roentgenoscopic studies are all of recognized importance and cannot be replaced by any complement test yet devised.

IMMUNIZATION AGAINST MEASLES *

D. L. RICHARDSON, M.D.
AND
HILARY CONNOR, M.D.
PROVIDENCE, R. I.

Measles is perhaps the most widespread and common of all infectious diseases. Practically all human beings are susceptible to it. If one escapes a childhood infection, adult life is no protection. No age, sex, race or climate is exempt. Contrary to popular conception, it is a disease serious to life. In the year 1913 it was the cause of 8,108 deaths in the registration area of the United States, embracing 65 per cent. of the total population. In the same year, there were 5,498 deaths from scarlet fever. While the mortality is highest in children under 5 years of age, and particularly under 3, the recent experience in the army camps of this country shows that it may produce a high mortality among adults under certain conditions.

Methods of controlling this disease in private life or in institutions have been of little avail, so that any new method that bids fair to produce results should receive a trial.

Very little has been attempted toward the immunization against measles. In 1915, Dr. Charles Herman of New York reported some work done by him.

His experiments were suggested by the fact that children under 6 months seldom contract the disease, or if they do contract it they have it in light form. Forty infants were inoculated. The virus was collected on cotton swabs from the nose of patients twenty-four hours before the appearance of the rash. These swabs were rubbed gently over the nasal mucosa of the forty infants. The majority of the infants showed no distinct reaction, fifteen had a slight rise in temperature, and in a few instances a small number of spots were noted on the face and body. Since then, four of the forty (being over 1 year of age) have been in intimate contact with cases of measles and none have contracted the disease. Two others of the forty were reinoculated at the age of 21 and 23 months, respectively, with a negative result.

The attempt at immunization against this disease was suggested by Dr. Charles V. Chapin. The basis of his suggestion was the use of virus and immune serum for immunization against hog cholera. This method has had much success.

The only other attempt to immunize with convalescent serum was reported by Nicolle and Conseil,[1] who used serum from a child, the first case in a family of four children. Two of the other children were not treated, but a child 2 years of age was given serum from the first case, taken on the seventh day of convalescence and ten days after the first symptoms. The

other two children came down with measles in three or four days, but the 2-year-old escaped, although exposed to the first child and later to his two brothers.

Two methods were followed by us: first, the use of convalescent measles serum alone, and second, the simultaneous inoculation of the patient with both virus and immune serum. From what we know of passive immunity, it is hardly to be expected that a permanent immunity could be induced by the first method. More could be expected of the use of both virus and immune serum. The first method was easiest to apply, as inoculation experiments with virus in institutions require considerable courage and judgment. Three such experiments were done, however.

The first group to be reported on was passively immunized with convalescent serum. The term "passive immunity" is used, although so far as is at present known this immunity might be quite permanent.

The second group, consisting of three patients, was inoculated with both virus and convalescent serum, and it might be conceded that an active immunity resulted.

The opportunity to do this work came in the spring of 1918, when there was much measles in the city. It was so prevalent that in spite of precautions to learn whether children admitted for other diseases had been exposed to measles at home, errors would occur. It so happened that there were instances in which children were admitted with other diseases during the incubation period; and when it developed, they were being treated in the same unit with other patients. It has been our experience that it is impossible to recognize the disease early enough to withdraw such children from among those whom they might infect, to save cross infection.

A careful history of whether the children selected for inoculation had ever had measles was obtained from the parents. Such a negative history is more to be relied on in the case of measles than almost any other infectious disease.

PASSIVE IMMUNIZATION AGAINST MEASLES

Blood Serum Preparation.—Blood was withdrawn from veins on the flexor surface of the elbow. It was collected in sterile test tubes marked with the name of the patient. These test tubes were placed in the refrigerator over night. Next morning, the serum was decanted into one or more sterile test tubes. The serum of each patient was kept separate. A Wassermann test was made of each patient's serum. Serums of different patients, reacting negatively, were then mixed for treatment. Record was kept of the time after the date of the rash when patients were bled. The serum was kept in the ice-box for a week at most, without addition of a preservative. If it was kept longer, a 0.25 per cent. solution of tricresol was added.

The serum was given intramuscularly, into the thigh, usually a single dose within a few days of exposure. No reactions, either local or general, were noted. Dosage was from 7 to 25 c.c., usually a single dose.

Group 1.—*Use of Serum on Nonimmunes Exposed to Measles.*—The first group of patients, four in number, were in a convalescent diphtheria ward with sixteen beds. These patients mingle freely. They were the only children who had not had measles, and the parents of each were interviewed carefully to obtain the history. They were exposed to two patients who came to the hospital during the incubation period. The first, Norma I., aged 6 years, had been in this ward five days when the rash began on May 5. Helen F., aged 8 years, had been in this ward three days when the rash appeared on May 9. They were both moved out of the ward at the appearance of the rash, yet they were there during the most highly infectious period.

Shirarina C., aged 16 months, and Alfred D., aged 2 years, were each given 15 c.c. of convalescent serum on May 11. The serum used was from five patients taken nine, nineteen, eight, twenty-five and seven days, respectively, after the rash of measles. Neither of these patients developed measles, and they were observed throughout the period of incubation, as were all of the exposed patients.

Lillian W., aged 13 months, was given on May 1, 6 c.c. of convalescent serum, taken from three patients, which had been collected ten, nine and twenty days, respectively, after the rash. This patient showed no signs of measles.

The fourth child, Gaetano F., aged 18 months, of this exposed group of nonimmunes, was used as a control and was given no convalescent serum. May 24, she developed a typical measles eruption.

Group 2.—May 13, a patient with laryngeal diphtheria was admitted to the laryngeal room with three or four other patients. All patients were treated in the same unit, no precautions being taken by physician or nurse. Being very ill, they were given much nursing by a special nurse, night and day. May 15, it was learned from the mother of the patient with laryngeal diphtheria that there were six cases of measles in her house. The child was at once examined, and many Koplik spots being found, the child was removed to another ward.

In this room were two children who had never had measles. Raymond B., aged 1 year, was given, May 18, 15 c.c. of serum obtained from five patients taken nine, four, four, fourteen and six days, respectively, after the measles eruption. The patient did not develop measles.

Alfred A., aged 4 years, was given 15 c.c. of convalescent serum, May 16, obtained from two patients eight and ten days, respectively, after the rash. This patient did not develop measles.

Group 3.—June 2, Veronica L., aged 3 years, developed a measles rash in the laryngeal room. She was removed at this time.

In this room, in the same unit, was Willard D., aged 7 months, who had never had measles. He was three days with the preceding patient. He was given 15 c.c. of convalescent serum, June 2, taken from a mixed serum from eight patients five, six, eleven, nine, eight, seven, ten and nine days, respectively, after the rash. He did not develop measles.

Patients Exposed to Infection Through Nurse.—June 13, Mary McD., a nurse, developed a rash while working in the scarlet fever ward. She had been working in the same ward for one week. There were three patients in this ward who had never had measles:

John W., aged 2 years, and Jeanette J., aged 3 years, were given 10 c.c. of serum, June 16, and Baby Moran 5 c.c. of a mixed serum from five patients taken thirty-one, nine, forty, six and five days, respectively, after the measles eruption. These three were observed throughout the incubation period, but did not develop measles. It must be taken into consideration, however, that the nurse during her duties washed her hands frequently, and may not have infected them.

Cases Occurring in Ward D.—A large room for from ten to twelve patients in this ward is so arranged that aseptic precautions can be taken, if necessary, each patient being isolated. The beds are about 10 feet apart, on centers, with no kind of partition between. We have not been entirely successful in preventing the spread of measles in such a room. It does control measles to a large extent, however. This explanation is made to make clear what is meant by partial exposure.

Shirarina C., aged 16 months (referred to above in Group 1), had been given convalescent serum, May 11. May 25, while in another unit, she was partially exposed to a child with a measles rash for about ten hours. Again, June 16, she was partially exposed in the same ward to a second child, who developed a rash, June 16. Shirarina C. did not develop measles, although she had received only the one dose of convalescent serum, May 11.

Howard D., aged 18 months, was partially exposed to a child who developed a measles rash in the same room, May 24, but not in the same unit. This exposure was over a period of several hours. Howard D. was given 10 c.c. of convalescent serum, May 27, taken from five patients nine, four, four, fourteen and six days, respectively, after the rash. Howard D. did not develop measles. Again, June 16, Howard D. was partially exposed to a second patient in the same room, but a different unit. Howard D. was not given any more serum and did not develop measles.

In the same room, in Ward D, June 16, Ralph L., aged 7 years, developed a measles rash. In this room, but in a separate unit, were three children who had not had measles.

Regina C., aged 1 year, and Camella B., aged 2 years, were also patients. The first was given 7 c.c. and the second 10 c.c. of mixed serum, June 16, taken from four patients seven, seven, nine and forty days, respectively, after the onset of the rash. Dorothy G., aged 7 years, on the same day was given 10 c.c. of serum, taken from five patients thirty-one, nine, forty, five and five days, respectively, after the onset of the rash. These three children did not develop measles.

ACTIVE IMMUNIZATION

Three patients were treated as follows:

Experiment 1.—Esther V., aged 4 years, was partially exposed to a child who, May 24, developed a measles rash in the same room, but in a separate unit for several hours. May 27, she was given 15 c.c. of convalescent serum, taken from three patients five, eight and ten days, respectively, after the rash. On the same day (May 27), direct swabs from the nose and throat of two children, who developed the rash on the same day (May 27), were taken. They were put back into the test tube, and were taken directly to the ward where Esther V. was then a patient. The nose and throat of Esther V. were thoroughly swabbed with this fresh secretion. The time between taking the secretions and the swabbing of the second patient was not over three or four minutes. Esther V. had pertussis and usually had a temperature of about 100. Twelve days later, a discrete hemorrhagic eruption appeared on her face, with a few scattered patches on her body. They were raised to the touch. They were most numerous on her face. On the same evening, the temperature rose to 103. Next day, subsequently, it remained as usual. The rash did not extend, and faded away in a few days. There were no Koplik spots or catarrhal symptoms, and the child sat up in bed as usual, not seeming to be at all ill.

This experiment seems to show that, if she was really infected, either naturally or artificially, and we have reason to believe she was, this patient did, twelve days after inoculation, show a reaction which may have been an abortive measles. If it was an abortive measles, even though the serum did not entirely prevent it, it showed inhibitive power. The reaction might have been due to the serum, but it was not like any I have ever seen.

The attack would never have been thought of as measles unless we had known of the inoculation.

Experiment 2.—August 11, Regina C., aged 1 year, and Morris S., aged 4 years, neither of whom had ever had measles, were infected with nasal and throat swabbings taken from a child whose rash began on the day before. Swabs were used on the donor, one of the nose and nasopharynx, and one of the throat. There was only an interval of two or three minutes before the inoculation was done. Both swabs were used in swabbing the nose and throat of the two children, Regina C. and Morris S.

August 12, each child was given 25 c.c. of a mixed convalescent serum, and this was repeated, August 14. The mixed serum was about 2 months old and was taken from eight patients five, six, eleven, nine, eight, seven, ten and nine days, respectively, after the rash. There was no reaction from the serum, and neither child showed any signs of measles in the hospital.

CONCLUSIONS

Six children were definitely exposed to measles and were apparently protected from the disease by immune serum; one, used as a control, developed measles. Eight others were partially exposed and did not develop the disease after immunization. Three other patients received virus inoculation and immune serum simultaneously. In two there was no reaction. In the third there was a slight reaction indicated by a transient rise in temperature and an atypical rash.

The experiments are too few to be conclusive, but they are sufficiently suggestive to warrant further investigation.

THE RELATION OF THE LYMPHOCYTE TO CANCER

L. D. BRISTOL, M.D., Dr.P.H.
State Commissioner of Health
AUGUSTA, MAINE

While the morphology of the various formed elements of the blood is now on a fairly scientific basis, there remains considerable lack of knowledge in regard to the origin and function of these cells. It is a matter of common agreement that the red cells are formed in the bone-marrow in adults and in the liver and spleen in embryos, while the origin of platelets is still in doubt. The polymorphonuclear leukocytes come originally from bone-marrow; the lymphocytes are derived from lymph glands and from tissue, and the large mononuclears have either the same origin as lymphocytes, or develop from endothelial cells lining blood or lymph vessels.

Not all the functions of these cells have been elucidated, although the evidence indicates that the red cells are concerned chiefly in tissue respiration, or the carriage of oxygen to the tissues; while the blood platelets are apparently involved in the phenomena of blood clotting. The white cells as a class are regarded as protectors of the body tissues against injurious agents of all kinds, and are intimately associated with the processes of inflammation. Polymorphonuclear leukocytes and large mononuclears are more involved in the defense of the body through an actual attack against the injurious agents, resulting in the engulfing (phagocytosis), neutralization and absorption of such agents. My opinion is that the small mononuclears, or lymphocytes, which are made up chiefly of nuclear material, have as their chief physiologic function the carriage in the form of nuclear enzymes of energy that is required by normal living body cells in the processes of growth and multiplication. Under abnormal conditions, and in concentrated numbers, these lymphocytes may give additional aid and energy to the normal body cells surrounding areas of injury and inflammation, thus causing a local speeding up of proliferation and repair.

In the growing embryo, the red cells apparently are the first to appear in the blood, which might be expected if cell and tissue respiration or oxidation is the prime factor in life. Of the white cells, the first to appear in the blood of the young embryo (usually about the tenth week of life) is a cell corresponding to the lymphocyte. Here again it is only logical that the cell which possibly has to do so much with growth energy should appear before the polymorphonuclear cell which has to do with the protection of that growth and life against injury.

During the entire fetal life, which involves characteristically rapid growth and multiplication of body cells and tissues, the lymphocytes remain the most numerous of the white cells; indeed, a relative increase or lymphocytosis persists during early childhood, the period of continuously rapid growth. At the time when body growth has reached its maximum, a definite change is found in the relative number of white cells in the blood, the number of lymphocytes being very much less than that of the polymorphonuclears, while at the same time the special auxiliary lymphoid tissues (such as the thymus) which have to do with growth rapidly atrophy.

It appears, therefore, that the lymphocyte possibly may be described as the male cell of the blood, and that through a process which is as yet not thoroughly understood, it has the power by means of the enzymes of its mass of nuclear material to energize the body cells with which it comes in contact, causing them to grow and divide. It is probable that the lymphocyte, or its energy substance, is under the constant control of an antibody, and that under normal conditions the influence of the lymphocyte and its enzymes is regulated for the exact demands of the body cells and tissues in their regular growth and division, or to meet the special requirements of increased local repair at points of injury.

It is my belief that as the controlled lymphocyte may be the potential father of normal body cells, so the uncontrolled lymphocyte may be the potential father of the tumor cell. The potential mothers of tumor cells are the epithelial cell, the connective tissue cell, the muscle cell or other tissue cells. The offspring of such unions may be the tumor cells themselves—the cancer cell, the sarcoma cell, the myoma cell.

The primary basis of cancer probably is a cell or tissue injury due to various physical, chemical, parasitical, mechanical or metabolic agents. The actions of such agents may be just as certain, even though they are not seen and appreciated. Because there is no history of cell or tissue injury is no reason to doubt this important precancerous factor.

Local injury is followed by local inflammation, and the latter involves the concentration of defensive polymorphonuclears and large mononuclears which attack the agents of injury, and also involves the concentration of the offensive lymphocytes with their energy-bearing enzymes, which may stimulate the surrounding tissue cells to more rapid proliferation and repair. It is significant that the lymphocytes are usually more concentrated at the periphery of a lesion. They are apparently more in contact with and more concerned in the repair work of surrounding tissue cells than in the attack on injurious agents; that is, they are seldom, if ever, phagocytic. These fundamental principles of my theory in regard to malignancy have been outlined in previous articles on the subject.[1]

In the warfare between injurious agents (especially bacteria) and body cells, the polymorphonuclear leukocytes making up the standing army rush to the defense of the body at the point of attack, and by an offensive campaign either destroy the invaders or are themselves destroyed. The endothelial leukocytes constitute the ambulance corps and bear away dead or injured bacteria, polymorphonuclears or other blood cells. The lymphocytes, on the other hand, make up the army of reconstruction. If the repair is of a normal nature, well controlled by antibodies, the result is normal healing. If the repair is of an abnormal nature due to the lack of controlling forces or antibodies, the result is lawless repair or cancer.

Thus cancer may be due to two factors, one local, the other general—a local cell stimulus which is set up by the energy-bearing lymphocytes concentrated by any form of local injury (usually chronic); and a general loss of lymphocytic control due to an acquired or possibly hereditary lack of antibodies in the tissues or circulation. Hence, cancer may be the result of an autoparasitism, in which local accumulations of uncontrolled lymphocytes are the important factors. The prevention and cure of cancer possibly may be brought about by the active or passive increase of the controlling lymphocytic antibodies.

That there is evidence from the work of various investigators to strengthen this hypothesis is indicated by a study of the literature on the subject.

Virchow[2] was probably the first to suggest an analogy between the fertilization of the ovum and the development of the cancer cell. Klebs[3] called attention to the common association of leukocytes and cancer cells, and believed that the former might fertilize epithelial cells and cause the latter to develop into cancer. In a study of resistance against transplanted mouse cancer, Bashford[4] found that the injection of normal mouse blood corpuscles induced a definite resistance against transplanted cancer. It is possible that corpuscular antienzymes were thus stimulated, with the result that the cancer cells could not find proper energy soil for their development.

Lewin,[5] in like manner, produced resistance against both rat carcinoma and rat sarcoma by the injection of normal rat blood; while Weidanz[6] obtained somewhat similar results with normal blood inoculations. Apolant[7] reported induced resistance by the injection of normal blood even from alien species. DaFano[8] associated the lymphocyte with the distribution, or stimulation, of immunity against transplanted cancer. Bashford, Murray and Cramer[9] showed that active resistance in mice against transplanted cancer might be developed as soon as four days after the inoculation of normal mouse blood, but that the resistance was greater after ten days—evidence of the stimulation of antibodies. Bashford, Murray and Haaland[10] demonstrated that as high a degree of immunity could be established by inoculation of normal blood as by injection of blood from tumor-resistant mice.

Collection and concentration of lymphocytes are very commonly found around growing spontaneous tumors and around living tumor grafts. DaFano[11] believes that in the latter the lymphocytes are concerned with the development of resistance against such grafts. Murphy and his co-workers[12] have shown that mice in which lymph glands and lymphoid organs have been unfavorably affected by roentgen-ray treatment are especially susceptible to the growth of transplanted tumors, and they believe that the lymphocyte is a potent factor in establishing the immunity of mice to transplanted cancer. More recently Murphy and Sturm[13] have demonstrated that after stimulation of lymphoid elements by heat, tumor grafts are much less successful. Corson-White,[14] in a study of the blood of tumor rats, following cancer-stimulating and cancer-inhibiting diets, found no change in the counts of red cells and no change in the numerical counts of white cells, except in the case of lymphocytes, and here definite changes in their numbers were noted.

One of the most striking and characteristic, as well as fatal, features of cancer is the spread of metastases, usually through lymph spaces and glands, less frequently through the blood stream. Instead of encountering resistance in lymph glands, cancer cells apparently find in lymph cells and tissues a lack of resistance or a definite nutritive soil and extra supply of energy for their continued growth and uncontrolled multiplication.

May we not say of metastatic cancer cells in lymph glands what Herbert Spencer[15] said of plants and animals in general? "The multiplication of any kind of plant or animal in localities that are favorable to it, is a growth where the antagonistic forces are less than elsewhere." What an important step it would be in the solution of the cancer problem if it were possible to control the spread of metastases by causing lymph glands to be actually antagonistic to cancer cells!

It is a significant fact that roentgen rays have an apparently specific effect on cancer cells, spermatozoa, ova and lymphocytes. Their effect on blood corpuscles other than lymphocytes is not marked. Does this not indicate a similarity in the basic substances or energy of such cells?

Based on this theory of the relation of localized uncontrolled lymphocytes and their nuclear enzymes to the energizing of epithelial cells leading to lawless reproduction, or cancer, experiments are being carried on in our laboratory to determine a possible means of controlling lymphocytes and cancer. These experiments will be described in a subsequent communication.

Racial Factors in Tuberculosis.—The findings in the Framingham demonstration as to racial factors bear out previous experience elsewhere, namely, that the Italian race stock presents a low tuberculosis incidence, in contrast to high rates in French-Canadians, Irish and other race stocks. On the other hand, the von Pirquet skin reaction among children shows a high percentage of infection among Italian children, with a correspondingly low incidence of active disease.—*Bulletin*, National Tuberculosis Association.

THE NEEDS OF MEDICAL EDUCATION AS REVEALED BY THE WAR[*]

EDWARD L. MUNSON, M.D.
Brigadier-General, General Staff, U. S. Army
WASHINGTON, D. C.

It is regretted that accurate statistical data to support statements made herein are not yet available, but lack of time as yet has made impossible the analysis of the vast amount of data in the records of the Surgeon-General's Office pertaining to this subject. But the Surgeon-General's great interest in this matter will doubtless result in a critical study of the data and a presentation of the results at no distant date. I do not comment further with respect to the probable results of this future statistical study other than to venture the conviction that they will prove disconcerting to any who may have entertained the idea that general standards of medical education in this country have reached a satisfactory degree of excellence.

You are accordingly asked to consider the following remarks as merely suggestive, as preliminary to the exact information later to be available, and as only embodying general impressions that I gained of medical officers under instruction at medical officers' training camps while I was in general charge of Medical Department training from May, 1917, to May, 1918. During this period I made frequent visits to the several camps located at Fort Benjamin Harrison, Ind.; Fort Riley, Kan.; Fort Oglethorpe, Ga., and Allentown, Pa. The camp at Fort Des Moines, Iowa, was also an instruction center and was duly visited, but was for colored medical officers only.

While accurate figures are lacking, it is doubtless true that more than half the medical officers who entered the service passed through the above named camps. The impressions gained were largely derived, of course, from the commandants of these camps and other officers pertaining to their respective staffs of instructors. They were accordingly second hand to a very considerable extent, but had the advantage of representing the composite ideas of large numbers of instructors.

For the period from May to October, 1918, I was in command of Camp Greenleaf, Fort Oglethorpe, Ga., and consequently was in close contact with the medical officers sent for instruction there. Camp Greenleaf at that time was handling over four fifths of medical officers sent to camps for training, as the camps at Fort Benjamin Harrison and Fort Des Moines had been discontinued, and those at Fort Riley and Allentown greatly cut down. Camp Greenleaf had then some 2,500 officers under instruction at one time, of which over 2,000 were medical officers and the remainder were student officers of the Dental, Veterinary and Sanitary Corps. With the concentration of training, these officers came to Camp Greenleaf from every part of the United States, so that they represented a fair cross section of the medical profession of the country, as it was accepted for service in the Medical Corps of the army.

In this connection, I would say that the opinions of Col. W. N. Bispham, Medical Corps, who will doubtless discuss this paper, should be of equal or greater value than any here expressed, for as commandant of the medical camp at Fort Riley, and later as commandant of Camp Greenleaf, he was in close relation with the student medical officers throughout the war, and had exceptional opportunities for personal observation from the standpoint of an experienced educator.

---

[*] Read before the Fifteenth Annual Conference of the Council on Medical Education of the American Medical Association, Chicago, March 3, 1919.

Most of the officers entering the army for the emergency volunteered for service from patriotic purposes. Probably few came in at the outset because of the draft. Later, with the raising of the age limit under the draft, a somewhat larger number probably were impelled to offer services which might later be requisitioned. Some actually appeared as drafted men; a few unwilling, others physically or otherwise rejected as officers, yet held to service by draft boards, and some who were graduates of low standard schools who had not been invited by the Surgeon-General to appear for examination for commissions. Practically all of these physicians who entered the service at medical training camps as privates were, it is believed, sooner or later examined as to their fitness to be officers. Some who had been previously rejected physically had their less serious defects waived and were given special duties which they could perform when the need for medical officers became more acute.

PERSONNEL OF ORIGINAL MEDICAL RESERVE CORPS

At the outset of the war, the list of civilian physicians already enrolled for such service as might be required amounted to some 1,600, and composed the Medical Reserve Corps of the United States Army. It was the first—and a most valuable—dependence of the Medical Department. Most of its members were promptly called to the colors, when they saved a most difficult situation in respect to meeting the early needs for the organization of the rapidly expanding medical service and the recruitment and care of the new troops.

This original Medical Reserve Corps was organized long before the European war, and at a time when the services of its members seemed little likely ever to be needed except to supplement to a small extent the regular Medical Corps on a peace time basis. It was merely a precaution and insurance of the Medical Service of the army and medical profession of the country against what was considered an improbable emergency. History shows how wise was this precaution, the inception of which was largely due to the forethought and energy of Gen. J. R. Kean of the Medical Corps.

But the nature of the conditions and ideas under which the old Medical Reserve Corps was organized had their influence on its medical standards and the medical examinations required for its enrolment.

In general, it might be said that it was composed of three classes:

(*a*) There were the recognized leaders of the medical profession, who lent the weight of their well known names and great professional reputations to popularize the then new Reserve Corps.

The abilities of these men were well known, and the examinations to which they were subjected were probably cursory.

(*b*) A somewhat smaller class probably consisted of a personnel drawn from the average class of practitioner, such as constitutes the backbone of the medical profession of the country.

Here also the examinations which they were required to pass were none too rigid; but by reason of the accepted candidates' being qualified in fact, no professional difficulty later occurred as a result of any professional inefficiency on their part.

(*c*) There was also a not inconsiderable third class, composed of less well qualified men, some of whom enrolled for patriotic purposes and others perhaps by reason of the desire to possess a commission signed by the President of the United States as a credential of professional ability additional to their diploma and license to practice.

These men likewise, in many instances, received an examination of less searching character. Possibly, too, some examiners were inclined to leniency as to standards, feeling that the offer of services of these men should be recognized by their acceptance unless grossly inefficient, and being comforted by the idea that there was little likelihood of their services being ever called on. Unquestionably, a number of the latter class of men should never have been recommended to the Surgeon-General for commission. As soon as they were called into service, questions as to their competency developed. If I recall correctly, the chief surgeon of the Western Department reported that he had, in his department, a large number of this class, representing largely a wandering type of physician who had temporary employment on ships, in the salmon fisheries, in mines, on plantations in Mexico and in South America, etc.

These substandard men were later reexamined, as their deficiencies became apparent, and doubtless all of them were ultimately eliminated from the service.

The number of these professional undesirables is not known to me, but my impression is that they probably composed some 15 per cent. or more of the old Medical Reserve Corps.

STANDARDS OF EXAMINATIONS

At the outset of the war, there is no question also but that some of the local examiners of applicants for appointment in the Reserve Corps did not maintain adequate standards for either physical or professional efficiency. Poor men were not rarely recommended for appointment. I assisted in the examination of a large number of papers of applicants, and helped to reject not a few who were obviously unfit. I have a vivid recollection, for example, of a candidate who was recommended by one examiner despite the fact that his papers showed that he was 68 years of age, was grossly obese, and further, had lost one leg below the knee.

The thought tended to occur, in such instances, as to whether the examiner was as much interested in securing competent medical service for the army as in helping diminish local professional competition.

Fortunately the number of such unduly lenient examiners was not great, and as soon as they were discovered they were promptly relieved from examination work. The men that they passed, however, added to the problem of elimination that had to be solved later.

It should be said here that most of the examiners were thoroughly conscientious, and the men whom they recommended were found to be qualified. Some examiners perhaps were even overstrict, as there were cases of men who were rejected and who were later drafted, and on being reexamined were found qualified.

As the war went on, the local examiners became better versed with the army requirements, and fewer mistakes were made. On the whole, the system of local examiners might be considered as efficient if duly checked up later. The number of undesirables, such as the professionally incompetent, physically incapacitated, men of bad character, alcoholics, drug addicts and others who were kept out of the service in this way, was very great. The experience of the Spanish War, when men were accepted for the Medical Service with little, if any, examination as to their fitness, was not repeated to any great extent. All this saved a vast amount of medical inefficiency and justifiable cause for criticism of the professional care of the disabled and greatly reduced the labors of later examining boards necessary to relieve the service of inefficients.

SELECTION OF MEN WHO REACHED THE MEDICAL TRAINING CAMPS

It must be emphasized that the medical officers who finally reached the medical training camps represented much better than the average of the medical profession of the country, for these candidates had been subjected to several processes of elimination:

(*a*) They had to be invited to appear for examination by the Surgeon-General, and unless they appeared to be probably desirable, this invitation might not be forthcoming.

(*b*) They had to be graduates of reputable medical colleges, which ordinarily eliminated men coming from institutions of poor character.

(*c*) They had to be licensed to practice in the state in which they lived, which would exclude medical graduates who had been found later to be not thoroughly qualified.

(*d*) They had to be in the active practice of their profession, thereby excluding the failures in medical practice who were making their living by some other vocation.

(*e*) They had to pass an examination before a local board, which had to be satisfied with their professional, physical and moral qualifications. Here occurred the greatest number of rejections, for the local board was in position not only to test out qualifications by examination, but in many instances it knew the candidate personally or by reputation, and was well informed as to his antecedent activities and conduct.

(*f*) Further, before being commissioned, the American Medical Association investigated and reported on their cases, to make sure that there was nothing in their career which should render undesirable their appointment as medical officers.

(*g*) Finally, the Surgeon-General had the right of rejection, which was exercised in the case of men who ultimately appeared from their papers to be not qualified for the service.

It is apparent, therefore, that a large proportion of the undesirables of the medical profession were excluded from service and never reached a medical training camp. The latter, therefore, dealt with an already selected class. That this selected class presented still further professional deficiencies invites reflection on the part of all those in charge of medical education.

ELIMINATION OF THE UNFIT

In spite of all the foregoing factors of preliminary elimination, not a few medical officers reported at medical training camps who were found by the examining boards there not fit for service. The number of those who were disqualified for professional reasons is not known. Further, figures on this point which may be later available will tend to underestimate professional inefficiency, for when men seemed professionally disqualified the tendency was to discharge them for physical disability if reason for such could be found to exist. This saved the reputation for professional competence of the rejected candidate after he returned to his home. This charitable method of disposal could be carried out more commonly than one might think, as many of the poorly qualified men were graduates of the poor schools of the past generation, were elderly, of sedentary habits, and often obese or with some pathologic condition or organic defect more common in the elderly.

This practice of rejecting the undesirables for physical rather than professional reasons, if the former was possible, was probably also common among local examining boards undesirous of provoking personal antagonisms and local criticism. For a physician to be found physically unfit for service carried no stigma—professional rejection did. Between the two horns of the dilemma, the choice tended to be along the easiest way for all concerned. But in any consideration of professional education and efficiency, these facts should not be overlooked.

As soon as the medical training camps had begun to function, it became apparent that one of their important fields of usefulness would be to act as filters to determine and eliminate the unfit. The commandants of the several camps accordingly appointed examining boards to examine all student officers, and on their recommendations reported for discharge all whom these boards found disqualified for service in any capacity.

These boards for some time were not fully accepted by the specialists' divisions of the Surgeon-General's Office, which had card indexed the men whose reputations seemed to warrant their acceptance as specialists. However, so many of these men were found, on examination, to be overrated by their reputations, that the specialists' divisions finally agreed to make their appointments as specialists tentative and subject to the examination held by their representatives on the general examining boards at training camps. The number of men claiming a specialty and not found qualified is given later. The number was considerable. It is interesting to note that a few alleged specialists were even found by the camp examining board unfit to practice any branch of medicine in the service. The others not qualifying were recommended for release from specialty and made available for general assignment. One deduction is that the general reputation of a man is not necessarily a criterion of his actual qualifications. Another, that in their estimates of each other gained by ordinary contact, physicians are not infallible. Another, that a large number of men actually practicing as specialists in this country, and generally accepted as such, are not duly qualified as the experts they are supposed to be. The latter point is one of special interest and concern to those interested in postgraduate and specialist education in this country.

In May, 1917, department surgeons were provided with a systematized course of instruction, necessarily largely a matter of personal reading, which was to be carried out by medical officers at the military posts and relatively small stations under their jurisdiction. Commanding officers were made responsible for the effective carrying out of this course to the extent practicable under local conditions. The Inspector-Generals were also charged with seeing that this work was carried out.

Toward the end of 1917, it became probable that a campaign of public criticism against the professional competence of medical officers was about to be prosecuted. It is believed that this was one phase of systematic German propaganda. To forestall this, medical "training officers" were put in every division and large medical organizations, whose business it was to determine defects, outline remedial instruction, and see that that qualification was insured by certification by a local board of examiners.

During the eight months of 1917, there were issued five orders or circulars to promote the instruction of medical officers and secure the elimination of those who could not be qualified. These were evoked by the fact that the qualifications of medical officers actually commissioned for service were not, as a whole, satisfactory. The intent of the foregoing orders was to reach out, determine the proficiency of all medical officers except those overseas, and either rectify their faults or cause their elimination from the service. Those eliminated were discharged for professional, physical or moral deficiencies; they were not discharged for ignorance of military methods and affairs, for it was realized that all were necessarily learners in such respects.

In connection with the examination of medical officers at the medical training camps, the need for medical officers, which always exceeded the supply, had to be borne in mind. It was realized that the Medical Department had a multiplicity of functions to be performed, some of which required the possession of a certain medical knowledge without necessarily a high degree of efficiency. There were, for example, many executive positions in hospitals and other formations to fill, recruits were to be examined, sanitation to be maintained, and enlisted men to be instructed and controlled.

EMPLOYMENT OF PARTIALLY QUALIFIED MEN

Instead of the uniform rejection from the service of all who were not fully qualified for the general practice of the medical profession, it was accordingly early recognized that there were "misfits" as well as "unfits." Partially qualified medical men were not without value. Experience proved that it was possible to economize in personnel without detriment to the efficiency of the medical service by placing the less well qualified men in positions of restricted professional activity where they could be of as much use as the better qualified men, who might thereby be released for higher professional duties. These men of less professional competence were assigned to special duties for which high professional competence was not essential. Frequently this was an advantage. The country doctors who had retrograded professionally might have an excellent ability to handle men and transport, and accordingly might be safely assigned as junior officers in ambulance companies. Some were good executives and made successes as adjutants. Others could safely be trusted with certain work in the examination of troops. Some could be trained in sanitary inspection, and took to this work with avidity and efficiency. All this is mentioned to emphasize the fact that even by boards in training camps, medical officers not fully qualified professionally were often not rejected but advantageously held to certain medicomilitary duties, although their examinations showed that in purely professional matters they were not properly qualified to practice.

Any later figures for discharge from the service for professional inefficiency must therefore be recognized as by no means including all the professionally inefficient, many of whom were held to duties which were executive or only semimedical in character, or in which only an elementary or highly restricted medical service was required. It can never be known how many of these substandard men were held in the service in this manner. I would hazard a guess that perhaps 10 per cent. of these who came to training camps fell within this class. In any consideration of the efficiency of methods of medical education in this country, they could not be disregarded; for if the Medical Department had no other duties to perform than the professional care of the sick, this class of officers would have had to be rejected.

The same principle was applied about the end of 1917 to the medical personnel with troops and hospitals. Orders directed the transfer to divisions of medical officers in hospitals who seemed not adapted to the latter work; conversely, as certain professionally well qualified men seemed physically or temperamentally unsuited to service with troops, division surgeons were ordered to transfer such to hospitals. No officer was to be discharged unless he was found unsuited for the performance of any duty under the Medical Department in both these classes of service. The results in numbers so discharged are not known. It is believed that the number of unfit so eliminated was not inconsiderable.

RECLAMATION WORK

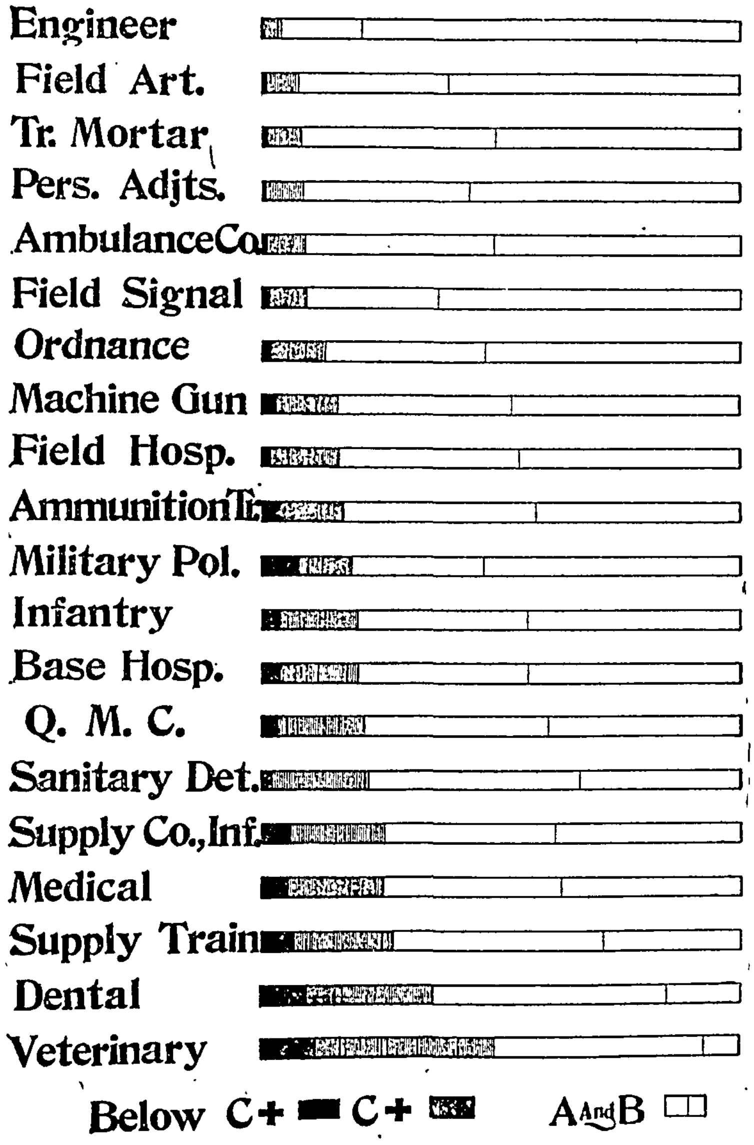
The medical examining boards at camps were further confronted with a class which was at once not qualified to be professionally passed, yet presented possible susceptibility to improvement and was too good to be discarded summarily. Accordingly, "salvage classes" were started, the members of which were systematically and intensively quizzed by expert quizmasters. This reclamation work had to be carried on in conjunction with more or less of the camp general curriculum, and called for interest and effort by all concerned. The men assigned to join these salvage classes were those who seemed bright and energetic enough, but who, for one reason or another, had not kept up with medical progress along certain lines. The subjects in which they were quizzed were only those in which they were found deficient. The great majority welcomed the opportunity thus to refresh themselves. The reclamation course usually covered about three weeks, when the candidates were reexamined. Nearly all qualified at the later examinations. The number varied. At some times, the reclamation classes at Camp Greenleaf amounted to as much as 6 or 8 per cent. of the student officers' group.

This experience would seem to carry a moral for medical educators. Have they not a field of usefulness in civil life whereby men who were originally qualified but who later deteriorated could have their deficiencies brought home to them and then effectively removed?

Much the same conditions in hospitals were met by orders early in November, 1917, by which it was contemplated that chiefs of service should seek out and see to the remedy as far as possible of the professional deficiencies of their subordinates.

QUALIFICATIONS OF CANDIDATES

The figures in Tables 1 and 2 are taken from reports by the board of examiners in session at Camp Greenleaf from Aug. 6, 1918, to Dec. 17, 1918, after which date no more candidates appeared. They show the relative classification by the board of accepted candidates. The examinations were searching, but thoroughly fair and practical. An expert in his line examined in each subject. The examination was practically standardized. Probably the qualifications of a large number of American practicing physicians and surgeons of the better class had never before been so thoroughly ascertained and fairly analyzed.



Proportion of high and low grades in various officer groups: The proportion of A grades varies from 8 to 79 per cent.; the proportion of A and B grades combined, from 52 to 96 per cent., and the proportion below B, from 4 to 48 per cent. Note the remarkably high ratings of engineer officers.

It is obvious that the board found the proportion of really high grade men in internal medicine to be small.

These figures include a few men qualifying for limited surgical work only, as abdominal surgery or orthopedic surgery.

They also indicate that only one medical officer in three was qualified to do independent surgery, and that only about 6 per cent. were really high class surgeons.

These examination findings seem to show that even with the quite carefully selected medical men entering the service, representing a type much better than the average of the profession, their qualifications, from the standpoint of both education and practice, cannot be considered satisfactory.

RELATION OF QUALIFICATIONS TO STANDARDS OF MEDICAL SCHOOLS

In a general way, it may be said that the general professional qualifications of officers bore a close relation to the educational standards of the schools from which they graduated. This was what would be expected. But various instances were noted in which graduates of good schools made a poor professional showing. Possibly an explanation might be that such men, while students under stimulation by the faculty, might do passable work, but that on graduation their natural inertia asserted itself, and not even professional competition furnished a sufficient incentive to them to keep abreast of medical progress.

The men from the poor schools naturally showed themselves less well qualified. Their professional foundation was poor, and the majority were permanently handicapped by it. On the other hand, their defects were perhaps not wholly the fault of the schools, for an able, ambitious man might, by his own initiative and later study, rise above his school environment. But the men from the poor schools were perhaps generally of a poorer type and not as alert mentally. The poorer schools very likely got men who were unable to succeed at better schools and were dropped therefrom. Some of these men were relatively sluggish mentally, and never had been provided by the Creator with the mental qualities necessary to the proper pursuit of medical science.

The thought is inevitable that medical schools should require a satisfactory psychologic rating for candidates for admission to a course leading to the degree of Doctor of Medicine, to make sure that they have the mental aptitude to qualify properly for it.

PSYCHOLOGIC TESTS

The psychologic tests of officers and men at Camp Lee, as shown on the accompanying chart, should be a shock to the complacency in this respect of our profession, for of all the different groups of officers at that camp, engineers, infantry, artillery, medical, etc., the group of physicians ranked lower in mental alertness than any other group of the military class, except the supply train, dentists and veterinarians. These scientific findings were abundantly borne out by experience, and if memory serves correctly, the chief surgeon at that camp recommended some 40 per cent. of his medical men for discharge as not qualified for service. This group of medical officers at Camp Lee was further investigated in a general way as to their antecedents, and was found to have largely come from poor schools and small communities and to have represented an exceptionally poor class of the general run of medical officers.

The question presents itself as to whether the medical schools are doing all that they should to keep out of the medical profession a class of men whose mental capacity is such that they can probably never rise to its opportunities and requirements. I believe that modern psychologic tests might be used with advantage to that end in respect to entrance examinations for medical schools.

QUALIFICATIONS OF ALLEGED SPECIALISTS

A very large proportion of alleged specialists were found in examination to be, in fact, only partly qualified. However, they had a basis of special knowledge of greater or less extent, and to render them properly qualified, special schools were organized to which approved candidates were sent by the examining board. These schools were staffed with the ablest professional specialists in the country, and there was a school for each specialty required in the army. Their courses were highly practical and intensive, and the student officers appreciated their great value. They met an obvious need. The thought presents itself as to whether the specialists' courses of instruction in the civil institutions in their country are doing the best that they might do along these lines. The thought also presents itself as to whether standards for specialists should not be higher, and whether some special recognition for excellence, such as the Doctor of Public Health degree given for demonstrated excellence in sanitary science, is not worthy of extension to other specialties. For a man to claim the qualities of an expert, even if his claims are accepted by the general public, does not make him an expert, and one of the chief functions of medical education is to safeguard the community.

TABLE 1.—CLASSIFICATION OF ACCEPTED CANDIDATES IN MEDICINE

Classification	Number	Per Cent. of Total
Qualified, plus	16	0.643
Qualified, good	216	8.176
Qualified	1,658	62.717
Qualified, junior	418	15.821
Qualified, junior, minus	334	12.641
Total	2,642	

Besides the general examining board at Camp Greenleaf, there was, as just intimated, a special board of professional experts which examined every officer reported by the Surgeon-General's Office as presumably qualified for a specialty. They also examined men claiming special competency in any subject, or referred to them by the general examining board as presenting qualifications worthy of further testing.

The results of the examinations of alleged specialists are given in Table 3. It is worthy of note that those rejected were not sufficiently well qualified to be recommended for special training in the courses in operation. In other words, they could not be considered as raw material, as being any more qualified for training in the specialties in which they claimed to be expert than was the average run of general practitioner. The approved men were sent to the specialists' courses for further instruction.

TABLE 2.—CLASSIFICATION OF ACCEPTED CANDIDATES IN SURGERY

Classification	Number	Per Cent. of Total
A plus	1	0.038
A	24	0.912
B	137	5.213
C	388	14.764
D	360	13.697
Qualified as assistant	590	22.450
Qualified as junior	937	35.654
Qualified as junior, minus	190	7.153
Qualified, minus	1	0.038
Total	2,628	

It is possible that some of these alleged experts claimed a special knowledge in the hope of being assigned to the special instruction course and thereby actually acquiring a specialty. In most instances in which a special knowledge was assumed, however, the student officer claimed to have been actually practicing the specialty. In some, the depths of ignorance were abysmal. I have knowledge of one examiner of international fame, ordinarily the essence of courtesy, who was impelled by the ignorance of a candidate who had been practicing as a specialist to say: "Doctor, by what assumption of impudence do you assume to claim yourself as a specialist?"

DEFICIENCIES OF MEDICAL EDUCATION

What has been said may be food for thought pending the accurate detailed statistical information which will later be available. Some of the deficiencies of medical education are apparent from the foregoing. Generally speaking, it would seem that the average physician has not been sufficiently well educated from a general standpoint, that the average facilities do not keep him abreast of medical progress, and that many men practicing as specialists need to be better trained. Specifically, the average physician knows little of preventive medicine, hygiene and sanitation, and these subjects should be given far more importance in the curriculums of medical schools than they are now receiving. It would seem that higher efficiency should be insured not only by the provision of appropriate facilities but also by more stringent examinations by the medical schools. The state boards have it in their power to insist on better qualifications for practice. The National Board of Medical Examiners can further the useful work by its standardizing of examinations, maintaining high professional ideals, and making its certificate the reward only of unusual professional excellence.

TABLE 3.—RESULTS OF EXAMINATIONS OF ALLEGED SPECIALISTS

Subject	Accepted	Rejected	Per Cent. Rejected
Ophthalmology	33	35	51
Plastic and oral surgery	44	27	38
Sanitation	44	17	28
Urology	100	18	15
Roentgen ray	83	4	4.6
Orthopedics	61	15	19

Neurology	8	2	20
Epidemiology	9	0	0
Anesthesia	22	5	18
Laboratory	19	4	17
Neurosurgery	10	1	9

CONCLUSION

I cannot forbear to express my admiration at the manner in which the profession in uniform adapted itself to conditions. Its members accepted cheerfully the results of the stock taking of their qualifications, even though the latter might not have been flattering. They cooperated in every way to remedy the defects thus made apparent. Their eyes were opened to any shortcomings of the profession as a whole, and it is safe to assume that their military experience has shaken them out of complacency, and given them new ideals and broader purposes. One of the results of the war will be a better and more competent medical profession, the members of which will look to the medical educators of the country to set high ideals and provide the facilities for their attainment.

Intermediate Host of Liver Fluke.—M. Muto has found that the *Clonorchis sinensis* has a second intermediate host. The first host is a river or lake snail; the second host a fish. The species of snails and fish involved are described in his report in the *Japan Medical World*, Feb. 2, 1919.

THE EPIDEMIC RESPIRATORY INFECTION AT CAMP CODY, N. M.

FREDERICK H. LAMB, M.D. (Davenport, Iowa)
Captain, M. C., U. S. Army; Chief of Laboratory Service,
AND
EDWARD B. BRANNIN, M.D. (Dallas, Texas)
First Lieutenant, M. C., U. S. Army; Chief of Pneumonia Section, No. 1
CAMP CODY, DEMING, N. M.

Sept. 24, 1918, there was admitted to one of the general medical wards of this hospital a soldier who had just come from Camp Dix, N. J., with prisoners. He gave a history of having been sick for three days on the train with headache, rhinitis, general aching, soreness in the chest, and cough. In addition, he presented a well marked pharyngitis. Within twenty-four hours from admission, we were struck with certain unusual features which his case presented. The pulse was slow in proportion to the high temperature. The respiratory rate was greater than physical signs warranted, and the leukocyte count was 4,800. Repeated physical examinations on that day finally revealed a few crepitant râles near the angle of the right scapula. In the afternoon of this second day, cyanosis of the finger tips became noticeable, and an ashy color of the face appeared. The condition in the lung spread rapidly to the left lower lobe posteriorly, and on October 1 he died. This was our introduction to the acute respiratory disease which was then prevalent in the Northern and Eastern camps.

Our epidemic may be said to have begun, Oct. 1, 1918, with the admission of nine cases which were diagnosed influenza, and from the standpoint of this report, it closed, Dec. 1, 1918. During this period there were admitted to the hospital 3,265 cases; the day of the greatest number of admissions was October 26, when 378 patients came in. October 30, the hospital, though its normal capacity is 1,200 beds, was accommodating 2,153 patients, of whom 1,899 had influenza or pneumonia. In 624 instances, or 19 per cent. of the 3,265, pneumonia was diagnosed. Death occurred in 7.3 per cent. of the total number of cases admitted, and in 38.4 per cent. of the pneumonias. Two hundred and forty deaths was the toll during the period mentioned.

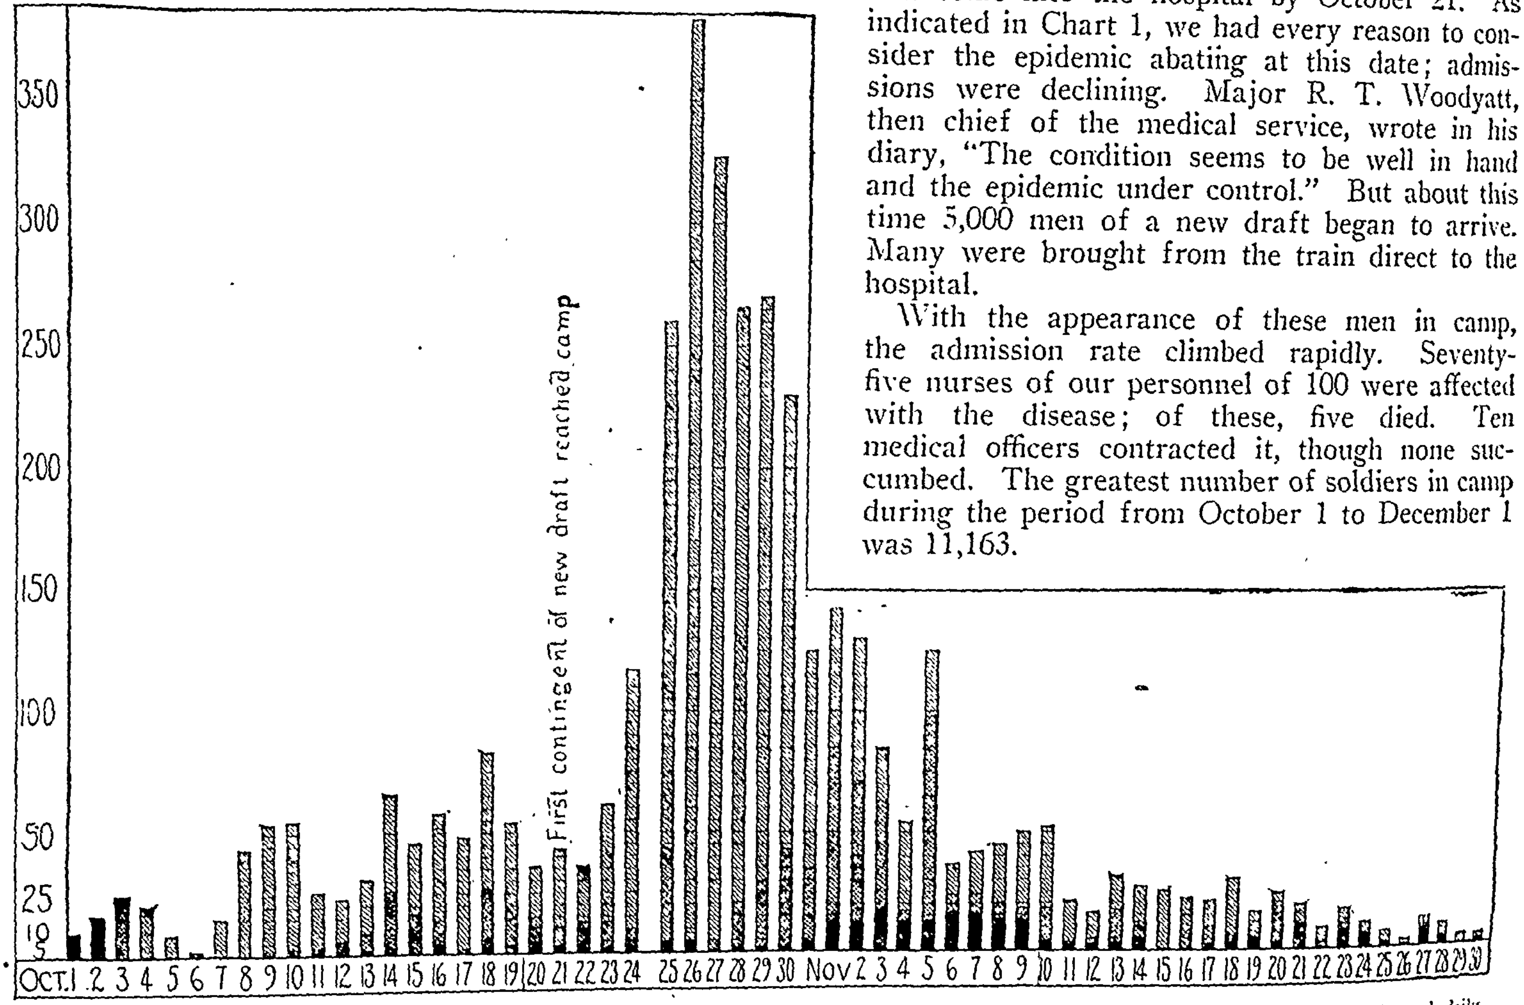

Chart 1.—Daily admissions for influenza (shown by diagonal shading), daily incidence of pneumonia (crossed shading), and daily deaths (solid black).

At the beginning of the epidemic there were 4,239 officers and men in the camp. Of this number 637 had come into the hospital by October 21. As indicated in Chart 1, we had every reason to consider the epidemic abating at this date; admissions were declining. Major R. T. Woodyatt, then chief of the medical service, wrote in his diary, "The condition seems to be well in hand and the epidemic under control." But about this time 5,000 men of a new draft began to arrive. Many were brought from the train direct to the hospital.

With the appearance of these men in camp, the admission rate climbed rapidly. Seventy-five nurses of our personnel of 100 were affected with the disease; of these, five died. Ten medical officers contracted it, though none succumbed. The greatest number of soldiers in camp during the period from October 1 to December 1 was 11,163.

ADMINISTRATIVE MEASURES FOR THE CONTROL OF THE EPIDEMIC

The camp authorities early instituted general measures to prevent the spread of the disease. Quarantine of the camp was established, congregations were prohibited, and a 5 foot space separated individuals at mess. Head to foot sleeping was insisted on. Bulletins were posted, giving instructions as to how best to avoid the infection and to keep up and improve the general health. Examinations were made twice a day of every soldier in the camp in order that detection of the disease in its incipience might be accomplished and new cases isolated promptly in the base hospital.

To the enlisted men an explanation was made of the early characteristics of the malady in order that it might be recognized, and they were urged to report to their medical officers for examination as soon as the symptoms were noted.

In the hospital, wards were designated for the isolation of these cases. Sheets were hung, providing a cubicle for each patient. Masks were worn by patients and their attendants at all times. Mess utensils were disinfected by boiling after each meal. The sputum cups were emptied and disinfected twice daily. Bags, with paper napkins, were used for the collection of nasal discharges. So far as possible, the air space allowance, as for pneumonia, was provided. Convalescents were not allowed to congregate in the wards, on the porches, or in the lavatories. A spray of dichloramin-T was used by nurses, attendants and officers. Antiseptic hand solutions were conveniently placed for those whose duties brought them into the ward. The wards were kept at an even temperature of about 80 F., though freely ventilated at all times. No patient was allowed to leave his bed until he had been forty-eight hours without fever. A convalescent hospital was established to which those patients whose condition, strength and period without abnormal temperature permitted it were sent in order to complete a ten day convalescence. To accommodate the vast number being admitted, beds were placed in the enlisted men's barracks, on porches, and in the corridors between the wards.

When pneumonia began to develop, special wards for the handling of these cases were set apart. Here too, the porches had to be used. During the height of the epidemic we were very grateful to receive the help of twenty-four nurses' aids sent by the Mountain Division of the Red Cross of Denver. Throughout the epidemic we received the cooperation and utmost assistance from the camp surgeon and other camp authorities. Medical officers from the 322d Sanitary Train and of the tuberculosis examining board were sent to assist in the wards. Their services were invaluable.

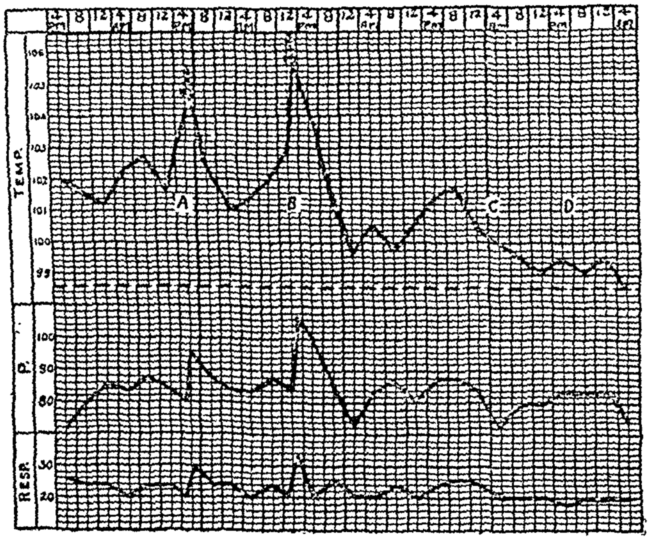

Chart 2.—Effect of an intravenous injection of bacterial filtrate: *A*, white blood count, 7,500; bacterial filtrate, 1 c.c. intravenously, 3 p. m.; *B*, white blood count, 10,000; bacterial filtrate, 2 c.c. intravenously, 1 p. m.; *C*, white blood count, 11,000; *D*, white blood count, 11,500.

LABORATORY FINDINGS IN INFLUENZA

Laboratory investigations were made during the first ten days of the epidemic in eighty typical cases of influenza. At the time of examination, none of these patients presented any physical signs of pneumonia or other complication. Nasopharyngeal and sputum cultures, blood cultures, blood counts and urine examinations were made in practically all of these cases.

Assuming that droplet infection was the most important factor in the dissemination of the disease, the bacterial florae of the nasopharynx and sputum were studied in detail. Nasopharyngeal swabs, obtained by means of West tubes, and specimens of sputum collected in sterile Petri dishes, were inoculated into blood agar and serum bouillon. Considerable pains were taken to identify colonies by subcultures in differentiating mediums. In order to gain some idea of the virulence of the organisms, fifty-eight white mice were given intraperitoneal injections of sputum.

It was found that there were five predominating pathogenic organisms: pneumococcus, *B. influenzae*, *Micrococcus catarrhalis*, staphylococcus and streptococcus, both hemolytic and nonhemolytic. Intraperitoneal inoculations of the pneumococcus, staphylococcus and both forms of streptococci were fatal to white mice. Injections of cultures of *B. influenzae* and *M. catarrhalis* produced only toxic symptoms in the mouse.

Nasopharynx and Sputum Cultures.—In eighty cases investigated, the organisms recovered from both the throat and sputum cultures showed the pneumococcus present in 90 per cent.; *B. influenzae* in 46 per cent.; *M. catarrhalis* in 84 per cent.; hemolytic streptococcus in 14 per cent.; nonhemolytic streptococcus in 26 per cent., and staphylococcus in 20 per cent. Colonies of both *B. influenzae* and pneumococcus were found in 41 per cent. of the plates. A few plates showed colonies of all these organisms. In many cases it was difficult to tell which was the predominating organism, and such a classification was given up as being unsatisfactory. Of the fifty-eight white mice that received intraperitoneal injections in 1 c.c. doses of ground sputum, nine, or 18 per cent., died. From seven of these the pneumococcus alone was recovered in the heart blood; from two, the pneumococcus and *B. influenzae* were recovered. The foregoing bacteriologic observations indicated to us that *B. influenzae* was not the specific organism.

Blood Cultures.—Fifty-four blood cultures were made in this series of eighty cases, all of which remained sterile.

Blood Counts.—The average of eighty leukocyte counts was 6,780. In fifty-four cases, or 67 per cent., the count was less than 8,000. The highest count of the series was 22,600, and the lowest 3,300. The differential count was not remarkable.

Urine Analysis.—Sixteen specimens, or 20 per cent. out of seventy-eight, showed a trace of albumin. Two cases showed considerably more than a trace, with a few granular and hyaline casts.

In connection with the experimental work, it is interesting to note that very soon after the epidemic of influenza reached this camp our laboratory guinea-pigs, housed in a small building beside the laboratory, began to die. At first it was thought to be the result of food poisoning, but a necropsy on a dead pig revealed unmistakable signs of pneumonia. The mucosae of the trachea and bronchi were deeply injected and covered with a glairy, serofibrinous exudate. Cultures and smears from this exudate and pieces of lung tissue revealed pneumococci in large numbers, a few streptococci and small bacilli, identical in every way with *B. influenzae*. These observations were confirmed in subsequent necropsies. The guinea-pigs were sick from two to four days before death. During this time, the sick animal trembling from chills, with hair ruffled, sat huddled up in a corner of the pen, moving about only to eat. This it would do until shortly before death. The respirations were rapid and wheezing; the characteristic shrill whistle became scarcely audible. The animal was apparently in a stupor which gradually deepened until death supervened. Altogether, it presented the picture of a profound intoxication. Just before death the animal would fall on one side, rise a time or two, then make a few feeble efforts to do so again. Within fifteen or thirty minutes it would die after several rather weak, clonic, convulsive movements.

All of the pigs in a batch of thirty died within three weeks. Fifty more were received from El Paso, Texas, just about this time, four of which were dead on arrival. The others were apparently healthy. These were placed in a different room of the animal house, which had not been in use for several months. It was thoroughly cleaned and supplied with fresh hay, which was changed daily. A heater was placed in the house, and every effort made to keep this new batch clean and healthful. No deaths occurred for about two weeks. One morning one pig was found dead, and within three weeks all of this second group had died just as the first had done. Segregating the sick animals did not save the others. It was planned by one of us (F. H. L.) to carry out a more detailed investigation of this epidemic among the animals which was so strikingly similar to the influenza epidemic in man, but an attack of influenzal pneumonia prevented the carrying out of the plan.

CLINICAL OBSERVATIONS OF INFLUENZA

Little need be said of the symptomatology of this disease. It differed in no particular, at this camp, from that reported in other localities. From the first, the symptoms were characteristic; there was little chance of confusing it with the ordinary respiratory infections.

The onset was more frequently sudden than otherwise, with chill or chilliness, cough, backache, headache, and pains in the chest and limbs. Coryza was frequently present, but the nasal discharge was of comparatively small amount. Injection of the pharyngeal mucous membrane was commonly noted. Epistaxis was not unusual. Physical examination of the chest was, as a rule, barren of results in the early stages, though occasionally sibilant and sonorous râles could be elicited. Gastro-intestinal symptoms, nausea and vomiting were uncommon. Aside from drowsiness and headache, few symptoms of nervous system involvement were noted. The pulse was remarkably slow. The respiratory rate was but slightly elevated, and the temperature range was from 100 to 104.

The course of the disease was from three to five days, with the temperature declining by sharp lysis in uncomplicated cases. Subsequent prostration was no more pronounced than would be expected in any febrile disturbance of the same duration. Few complications, other than that of pneumonia, were seen. Otitis media was present in a very small proportion of cases, and in these it was of low virulence. No death was ever attributed to influenza alone.

The treatment was symptomatic. Acetylsalicylic acid or acetylsalicylic acid and codein were used to relieve aching. Simple expectorants, with or without opium, were given for cough. Initial purgation with oil was routine. Food, liquid and soft, was given at frequent intervals, with night feedings to those whose condition was unsatisfactory.

PNEUMONIA

As mentioned above, pneumonia occurred in 624 instances. In type, it was with few exceptions of a lobular variety. Clinically, it was considered a hemorrhagic atypical bronchopneumonia. The massive consolidations were thought to be the result of the confluence of contiguous inflamed areas. It originated with equal frequency in the right and left basal lobes posteriorly. In only a very few cases was it noticed first in other locations.

TABLE 1.—COMPARISON OF TWO HUNDRED AND FORTY FATAL AND TWO HUNDRED AND FORTY NONFATAL PNEUMONIA CASES

	Fatal	Nonfatal
Number of days from pneumonia recognition to death.....	General average, 4.9 days	
Number of days from pneumonia recognition to normal temperature.......	....	General average, 3.9 days
Number of days in hospital before pneumonia occurred..............	General average, 3.8 days	General average, 4.0 days
Number of days with fever, dating from admission..........	General average, 8.5 days	General average, 7.9 days
Mental disturbance..	Recorded in 88 cases	Recorded in 13 cases
Pain in chest.........	Recorded in 33 cases	Recorded in 15 cases
Pulse.................	In 50% the rate was slow in proportion to temp. (exclusive of last 36 hrs.)	In 76% the rate was slow in proportion to temp. throughout entire illness
Respiration..........	In 68% of the cases the rate was over 36 per min. (exclusive of last 36 hrs.)	Only 16% of cases reached a rate of 36 per min. or over, during entire illness
Leukocytes...........	In 48% of cases the count was below 9,000; general average in uncomplicated deaths, 10,000	In 40% of cases the count was below 9,000; general average in uncomplicated cases, 11,400
Cyanosis.............	Recorded in 155 cases	Recorded in only 28 cases
Temperature.........	Higher level, 103 to 105 degrees with slight daily remissions	Lower level, 101 to 104 degrees with more marked daily remissions

In reviewing the records, certain interesting, though probably unimportant, figures have been obtained:

1. It was found that the average period of temperature, from admission into the hospital until death or normal temperature occurred, was approximately eight days.

2. The patients were, on an average, in the hospital four days before pneumonia began, or at least, until it was recognized.

3. From the date of recognition until death occurred, or until normal temperature was reached, was, respectively, 4.9 and 3.9 days.

Table 1 is interesting in that it indicates the symptoms on which prognosis depended, namely, respiration, cyanosis and a disturbance of mentality. We think that the leukocyte count comparison is of little value, as in most of the cases only one count was made, and that, soon after admission. The temperature in the fatal cases ran at a much higher level, in the majority of instances, than in the nonfatal ones.

The comparative bacteriology of the two series (the fatal and the nonfatal) is identical. Pneumococcus Type IV is the predominating organism in both, with the hemolytic and the nonhemolytic streptococcus frequently associated, and at times being independent. The presence of the latter organism did not seem to influence the mortality.

LABORATORY FINDINGS IN PNEUMONIA

With the development of pneumonia as the serious complication or sequel of a large number of influenzas, laboratory investigations were centered on these cases.

Blood Cultures.—Blood cultures were made in 248 cases of influenzal pneumonia. In only four of these, or 1.6 per cent., were organisms recovered, the findings being hemolytic streptococcus in one case and pneumococci in three cases, of which one was Type II, one, Type II, atypical, and one, Type IV. Many cultures made within a few hours before death remained sterile.

It was surprising to find such a small percentage of positive cultures in this epidemic. In two previous series (in the spring and summer of 1918) of pneumonia blood cultures, one consisting of ninety-two cases and the other of 180 cases, 26 and 18 per cent., respectively, were positive. The technic was the same for the two series.

Sputum.—The character of the sputum varied greatly. Many specimens were as thin and watery as saliva, and, being unfit for typing, had to be rejected. A fairly common specimen consisted of a few mucopurulent, slightly blood streaked, friable clumps floating in a thin, limpid liquid. These masses, when washed and ground, yielded fairly good typing specimens. The tenacious, glairy, blood streaked sputum, ordinarily seen in lobar pneumonia, was very rare in this series. The character of the sputum seemingly bore no constant relation to the bacterial flora.

Three hundred and forty-eight specimens were typed. Smears were made from the original specimens, blood plates poured and streaked, Avery's blood broth inoculated, and in about 50 per cent. white mice were given intraperitoneal injections to check the typing. On the whole, the typing was far less satisfactory in this series than it had been in the previous two series mentioned above. The readings of the agglutination and precipitin tests were far less clear cut. Yet the method used and personnel were the same.

TABLE 2.—TYPES OF PREDOMINATING ORGANISMS

Predominating Organisms Determined from Plates	*Number of Cases*		*Per Cent. of Total*	
Pneumococcus:				
Type I	9		2.60	
Type II	7		2.01	
Type II, atypical	24		6.89	
Type III	14		4.02	
Type IV	162		46.55	
		216		62.07
Streptococcus:				
Hemolytic	37		10.63	
Nonhemolytic	54		15.52	
		91		26.15
		307		
Predominance of any organism questionable		41		11.78
		348		100.00

Table 2 gives a percentage classification of the organisms predominating, so far as it was possible to determine predominance.

Table 3 shows the comparative frequency with which colonies of the five predominating organisms were found in the sputum cultures.

Blood Counts.—The average leukocyte count of 350 cases in the influenzal pneumonia wards was 9,480. Of these, 58 per cent. were 3,000 or under, and 73 per cent. were 12,000 or under. In only 5.4 per cent. was the count above 25,000 per cubic millimeter. This is a striking contrast to the high leukocytosis so universal in pneumonia.

PATHOLOGY AND POSTMORTEM BACTERIOLOGY

We were impressed with the fact that, taken as a whole, the patients who died were, if anything, somewhat better nourished and more robust than the average individual. The rapidity with which death took place precluded much external change. Postmortem lividity was usually marked; the finger nails and mucosae were very cyanotic. In about one half of the cases a foamy, blood-stained liquid ran from the nose and mouth when the head was lowered.

TABLE 3.—COMPARATIVE INCIDENCE OF THE FIVE MOST FREQUENTLY FOUND ORGANISMS

	Number of Cases	Per Cent.
Pneumococcus	310	89.1
Streptococcus	222	63.3
B. influenzae	89	23.0
M. catarrhalis	21	6.0
Staphylococcus	30	8.6

In all except one of the sixteen cases examined at necropsy, the postmortem picture was strikingly uniform. This exceptional case presented all the characteristics of a true, dry, lobar pneumonia. We shall try to describe the others as a group, limiting the detailed description to the respiratory tract.

The mucosae of the trachea and bronchi were intensely red, slightly edematous, and covered with a red, mucopurulent exudate. In many instances the smaller bronchi were filled with a red foam. The peribronchial lymph nodes were twice or three times normal size, very red, soft, and the cut surface granular. No changes were noted in the mediastinal space.

The lungs presented a picture quite distinct from anything we have seen before. The pathologic changes were certainly *not* those one is accustomed to see in the ordinary lobar pneumonia, nor were they typical of bronchopneumonia. In fact, the terminal hypostatic pneumonia, sometimes seen in the aged, compares more nearly, in gross characteristics, than does either of the other types.

In the fifteen cases that we have chosen to designate as *atypical, hemorrhagic bronchopneumonias*, the pneumonic process has been bilateral. In nine cases it was of nearly equal extent on the two sides; in six it was decidedly more pronounced on one side than on the other. In three cases there were extensive, dense, pleural adhesions; in four, there were recent, friable adhesions; in eight, the lungs were free. In two cases, there were 500 c.c. and 700 c.c. quantities, respectively, of a dark red, serosanguineous exudate. Both parietal and visceral pleurae were deeply injected. The lungs were voluminous and heavy. As a rule the posterior half or three fourths of the lung were a dark, purplish red, the remaining anterior portion, gray or pink. That this appearance was due to the filling of the posterior portion with dark red blood could be clearly demonstrated by an anteroposterior section. The posterior portion felt uniformly firm, yet somewhat resilient. The anterior part, especially of the middle and upper lobes, was elastic, soft, and air containing; here sometimes a discrete, irregular, consolidated area could be felt.

On section, a profuse bloody exudate welled from the cut surface of the consolidated portion. With slight pressure, 300 c.c. of this liquid could be drained from a single longitudinal section. That the firmest portions of the lung contained air could be demonstrated by the presence of numerous air bubbles in the exudate. Small sections from the more dense areas would barely sink in water; other sections floated. After the surface of a section had been squeezed and washed, the polygonal boundaries of the lobules could be plainly seen. A section through the anterior, air containing portion, which was rather sharply demarcated from the posterior consolidated portion, revealed a comparatively dry cut surface. Twelve out of thirty lungs presented peribronchial areas of consolidation from 1 to 4 cm. in diameter, in this air containing portion. The cut surfaces of these isolated areas bulged slightly, and were dark gray but not hemorrhagic. A mucopurulent exudate could be expressed from the bronchioles involved. These areas were typically those of bronchopneumonia. The marked hemorrhagic, edematous element was entirely lacking in this upper and anterior half of the lung; in fact, the gravitation of the blood and exudate to the posterior portion of the lung was striking.

TABLE 4.—POSTMORTEM BACTERIOLOGIC FINDINGS

Case Number	Organisms from Lung Cultures	Organisms from Heart's Blood
1	Pneumococcus Type II	Pneumococcus Type II
2	Pneumococcus Type III	Pneumococcus Type III
3	Pneumococcus Type IV	Pneumococcus Type IV
4	Pneumococcus Type IV	Pneumococcus Type IV
5	Pneumococcus Type IV	No growth
6	Pneumococcus Type IV and B. influenzae	Pneumococcus Type IV
7	Pneumococcus Type IV and B. influenzae	No growth
8	Streptococcus, nonhemolytic	No growth
9	Streptococcus, nonhemolytic and hemolytic	Streptococcus, hemolytic
10	Streptococcus, nonhemolytic and hemolytic	Streptococcus, nonhemolytic and hemolytic
11	Streptococcus, nonhemolytic and hemolytic	Streptococcus, nonhemolytic and hemolytic
12	Streptococcus, nonhemolytic and hemolytic, and pneumococcus	Streptococcus, nonhemolytic and hemolytic
13	Streptococcus, nonhemolytic and hemolytic, and pneumococcus	Streptococcus, nonhemolytic and hemolytic
14	Streptococcus, nonhemolytic and hemolytic, and pneumococcus	No growth

Gross changes in the heart or pericardium were not encountered. We found no evidences of dilatation on either side; the muscle was firm; the ventricles, usually contracted, contained a small amount of dark, semiclotted blood. The "chicken-fat" clots, often observed in pneumonia and slow deaths, were not found. Only the changes usually resulting from the toxemia of a severe infection were noted in the other viscera. We found no marked evidences of nephritis. The average weight of the spleen was 240 gm. It was usually of firm consistency; the cut surface moist and purplish red. A small amount of red, gruel-like pulp could be scraped from the surface. The bone marrow was pale, and quite noticeably dry: an observation in keeping with the leukopenia.

Bacteriologic cultures were made from the lungs and the heart's blood in fourteen cases.

CLINICAL OBSERVATIONS OF PNEUMONIA

In considering the clinical features, complications and treatment, we believe the value of personal observation will outweigh that of figures and statistics, since the attention to sick and dying men left insufficient time for the compilation of accurate data. It appeared, from the large number of cases (50 per cent.) that were definitely diagnosed as pneumonia, on the third, second and even the first day after admission, that many of them must be considered as primary lung infections and not in the light of true complications of influenza at all. We feel that this is true because with the onset of symptoms, soldiers from the camp were immediately sent into the hospital. Then too, in the majority of cases, there was no definite onset of pneumonia, as would be indicated by sudden increase of temperature, chill or other symptoms. Rather, there was from admission a gradually increasing toxemia, a gradual rise of temperature and respiratory rate, with the recognition of the existence of the lung disease dependent entirely, in most instances, on auscultatory findings. In 25 per cent. of the cases, however, there was a break in the temperature, a short remission or an intermission; then with a chill, an epistaxis, or a pulmonary hemorrhage there followed a sharp rise and the development of typical pneumonia findings.

Unquestionably, many patients diagnosed as having influenza of a severe type, who recovered and were sent to duty, had a slight pulmonary involvement which passed unrecognized. For this reason, it would seem that the mortality rate should be based on the total number of influenza cases admitted, rather than on the recognized pneumonia cases, since the recognition of the latter was dependent on the examiner's skill and the time he had to devote to each examination.

Physical Signs.—The earliest of the physical signs elicited and the one to which we attached the greatest importance was the finding of persistent showers of crepitant and subcrepitant râles. As the disease progressed, evidences of varying degrees of consolidation became manifest: bronchovesicular or bronchial breathing, increased voice and breath sounds, and dulness on percussion. Of the latter it may be said that the note was often almost flat, the result, evidently, of the intense inflammation of the lung and the filling of the vesicles and bronchioles with blood or exudate. Many cases were characterized by suppression of breath sounds, diminution of fremitus, and this dull-flat note. Often these findings led to unproductive aspiration. In only a few instances did the process stop with no other finding than that of crepitant râles.

The sputum, as a rule, differed from the thick, tenacious sputum of lobar pneumonia, in that it was more often purulent or, as seen in many cases, a thin, serosanguineous discharge. In some instances, large quantities of the latter type were expectorated, suggesting pulmonary edema by its fluidity, although it was not frothy. Nummular sputum was frequently seen.

One of the most interesting and alarming features was that of cyanosis. Often it was noticed before any other symptoms suggesting the serious condition of the patient manifested itself, and not infrequently even before the physical signs of pneumonia had been discovered. It varied in intensity from a slight duskiness of the face and finger-tips to that of the extreme grade in which the skin and mucous membrane were lilac. No satisfactory explanation of the exact cause of this cyanosis was given. It occurred in cases in which the lung involvement was slight. It was absent, at times, in cases with extensive lung involvement. It was not due to embarrassment of the right heart, as careful physical examination did not indicate right-sided failure of this organ. It was suggested by Major E. A. Duncan that the explanation was to be found in the action of the toxin on the alveolar epithelium, the resultant devitalization interfering with the normal functioning of these cells. The possibility of a vasodilatation leading to pulmonary congestion and edema also was suggested. Regardless of its cause, it was of ominous portent, and its clearing or absence was considered a very favorable omen. In Table 1 it will be noted that of the 240 patients that died, it was specifically noted in 155, and that, on the other hand, the records of an equal number of nonfatal cases mentioned it only twenty-eight times.

The respiratory rate, in our milder cases, was not greatly elevated. In fact, the records show that in 84 per cent. of the patients that recovered, it did not at any time go over 36 a minute. On the other hand, in the fatal cases the rate was high, and in 68 per cent. of these it was over 36, and this exclusive of the last thirty-six or forty-eight hours, when it frequently reached 50, 60 or even 70 a minute. The combination of cyanosis and dyspnea made the term of the older authors, "suffocative catarrh," particularly apt and expressive.

In the fatal cases the frequent appearance of indications of mental impairment was noteworthy. It varied in degree from simple drowsiness, as seen in the initial stages, to a slight mind wandering from which the individual might be called back to full consciousness by a spoken word. In some individuals it was manifested by a complete coma, and in others by an active delirium for which restraining sheets were necessary. This necessitated, in the severe cases, constant watching, since at times, patients, even in their terminal twenty-four hours, would attempt to leave their beds. In those that recovered, such symptoms were unusual; and when they did occur, the delirium was usually quiet. It was found in many of the patients presenting active mental symptoms, that there was an increase of intraspinal pressure with or without the evidence of actual meningitic inflammation. Unfortunately, the relief of this pressure by spinal puncture did not seem in any way to alleviate the disturbance. Associated in this syndrome there frequently appeared a general muscular tenseness, not often of sufficient degree to give rise to a positive Kernig's sign, but sufficient to offer resistance to every passive movement. Shivering, twitching, tremors and subsultus tendinum were present. These were considered cases of meningismus if the laboratory reported no increase in cell count or organisms in the spinal fluid.

Herpes was unusual. Jaundice occurred in a small percentage. Nausea and vomiting were infrequent. The cheek flushing of lobar pneumonia was seldom observed. When seen, it was most often found that a pleural effusion complicated the pneumonia. Practically all of the patients developing empyema showed this symptom. No purpuric spots were noticed. In the most serious cases the temperature was high with slight morning remissions. A few, however, had a low temperature notwithstanding their dangerous physical condition. Mouth temperatures in the moribund were very unreliable. The difference between the temperature curve of the severe and of the mild case was not so much in the height of the afternoon temperature as in the degree of the remission.

Termination.—Crisis was very unusual, lysis being the rule. Death, in the majority of instances, was quiet and easy. The pain in the chest, which had so often annoyed in the early stages, had been relieved probably by slight fluid accumulation; the toxemia or the products of semiasphyxiation had so benumbed the sensorium that the patient, unmindful of his dyspnea, died in comparative comfort.

COMPLICATIONS

Of the complications, the most frequent was that of pleuritis with exudate. In the group of fatal cases, a serofibrinous effusion of sufficient quantity to merit attention was recorded in twenty instances. Seven of these became purulent. In the nonfatal group it was more common, and resulted in thirty empyemas. The bacteriology of the fluids examined showed the streptococcus to be present alone in 36 per cent., the pneumococcus alone in 36 per cent., the streptococcus and pneumococcus associated in 20 per cent., and the staphylococcus in 8 per cent. A striking feature was the frequency with which the accumulation, probably beginning in a fissure, would press the lobes apart, giving a V-shaped area of fluid as seen with the roentgen ray, with the point of the V at the hilum of the lung and the open part at the chest wall. Physical examination in these cases naturally showed an area of compressed lung both above and below the fluid.

Otitis media was infrequent, although next in incidence, to the pleurisy. Phlebitis of the left leg occurred in three instances. Furunculosis and a tendency to small abscess formation was noted in a few cases. One case of cerebral thrombosis was recorded. Pulmonary edema, as a terminal condition, was often seen. Pericarditis was not found, and but one instance of acute endocarditis was observed. Meningitis with pneumococci in the fluid was recorded seven times.

Relapses or recurrences were unusual. Remissions in the severity of the process with subsequent intensification of symptoms, as early involved lung areas improved and new areas became infected, were seldom observed. Two cases of subcutaneous emphysema were recorded; both patients recovered. Spontaneous pneumothorax occurred in two instances. The picture of mild neurocirculatory asthenia was seen many times in convalescents. Reactivated, chronic tuberculosis was an unusual finding, in spite of the fact that many of our patients had never had their induction examination. Very few mental or nervous sequelae came to our attention. It was not unusual to find, long after recovery, the persistence of the physical signs of fluid in the bases, in patients in whom repeated aspiration had failed to establish its presence. We thought that this was due more often to a fibrinous pleural exudate than to an unresolved pneumonic process. Crepitant and subcrepitant râles in the bases were found in some instances to persist for a period of four or five weeks from the onset of normal temperature.

TREATMENT

General Measures.— The routine inaugurated early in the epidemic consisted of free ventilation; abundance of nourishing, easily digestible food; large fluid intake; absolute confinement in bed until convalescence was well established, and hydrotherapy for fever and nervous symptoms. Acetylsalicylic acid was discontinued on the diagnosis of pulmonary disease. The cough was controlled by an expectorant syrup, supplemented with heroin or codein, if its severity so demanded. All patients were digitalized if there was any indication of circulatory embarrassment. Whisky, camphor in oil, strychnin, caffein, atropin, epinephrin and pituitary solution were the stimulants in use. It was discouraging to note a lack of effect from any of them so many times, when stimulation was most urgently needed. Of these, it seemed that atropin was probably the most efficacious. An improvement, though temporary, in the cyanosis and dyspnea sometimes followed its use. No benefit from digitalis hypodermically or by mouth was ever established. Venesection was done but once. In a few cases, oxygen was administered; but as no improvement was noted, its use was discontinued.

Foreign Protein Treatment.—Early in October, a suggestion was made that immune serums, regardless of their nature, might be beneficial. The disease was characterized by a failure of response of the body's defensive forces. There was a leukopenia, a vasodilatation, an asthenia, and a pronounced hemorrhagic tendency. With these facts before us, we began the use of diphtheria antitoxin, hoping thereby, to increase the production of antibodies. Sensitization tests were carried out by a small subcutaneous injection. If in an hour no indications of anaphylaxis appeared, 10 c.c. were administered by vein. In forty-five minutes a sharp reaction (chill, fever and sweat) usually began. At the end of from twenty-four to forty-eight hours, if no marked improvement was observed, or if the patient was not moribund, a second dose was given. Only in exceptional instances were more than two doses used. With the progress of the epidemic and with the influx of hundreds of pneumonias, other varieties of protein were employed, such as antimeningococcic, antitetanic and antipneumococcic serums, and late in the epidemic the use of a bacterial filtrate was instituted. The latter substance, prepared from the organisms commonly present in influenza and pneumonia, was obtained from the laboratory of Dr. A. F. Schafer, Bakersfield, Calif.

In view of our death rate, which we know was about the average of that of other camps, we can scarcely make great claims for this treatment, for which we claim no originality. Nevertheless, certain conclusions are definitely fixed in the minds of the medical attendants who use it here :

1. Many cases, which appeared at their onset to be of the malignant type, would after its use show an improvement (often unexpected), with subsequent recovery.
2. No improvement resulted unless a reaction occurred. For this reason we were partial to the more concentrated products (diphtheria serum and bacterial filtrate.)
3. The same benefit was derived from the antimeningococcic, antitetantic and antidiptheritic as from the antipneumococcic serum, provided a satisfactory general reaction resulted. In other words, there was no apparent specific action of any type of serum, but the result was dependent entirely on its protein content.
4. Early administration was essential to effectiveness.
5. No harm, attributable to their use, was ever observed.
6. From the use of the serums there seemed to be a lessening of the hemorrhagic tendency.
7. While an artificial crisis was desired and anticipated, more often, when benefit did result, it came as a gradual reduction in toxemia, in temperature, and in respiration.

Of these products the bacterial filtrate was unquestionably the most satisfactory. Its concentration, the sharp reaction produced, the ease of administration (from 0.5 to 1 c.c. intravenously being used as an initial dose), and the absence of disagreeable urticarial or arthritic sequelae, all being in its favor. We regret that the stress of the epidemic prevented systematic, scientific observations of the factors that brought about the improvement and of the changes that resulted from the use of this treatment. But we who used it have definitely concluded that it was of no uncertain value in selected cases, though not by any means as much so as we optimistically felt in its inauguration.

NONTRAUMATIC HEMORRHAGE OF THE SUPRARENAL

REPORT OF CASE

FRANK B. LUSK, M.D. (Chicago)
Captain, M. C., U. S. Army
FRANCE
AND
ARTHUR BRUMBAUGH, M.D. (Altoona, Pa.)
Captain, M. C., U. S. Army
CAMP DODGE, DES MOINES, IOWA

While small hemorrhages into the suprarenal, ranging in size from a pea to a walnut, have been found not infrequently postmortem, acute hemorrhagic suprarenalitis, and more especially large nontraumatic hemorrhages, are rare. The fact that in this instance *Streptococcus hemolyticus* was isolated from the blood both antemortem and postmortem, and that the case followed shortly on an epidemic of empyema at Camp Dodge due to the same organism, leads to the supposition that this organism was the exciting cause. It seems reasonable to assume that by lodgment of a bacterial embolus either in a vessel wall or a vessel itself, a dissolution of the vessel occurred resulting in hemorrhage and death. The clinical picture up to a few hours before death was that of a severe septicemia, and such was the antemortem diagnosis.

REPORT OF CASE

History.—G. S., 2704293, white man, aged 27, born in South Dakota, was admitted to the base hospital at Camp Dodge, July 17, 1918, with the diagnosis, "Felon, third finger, right hand." The mother and father, four brothers and two sisters were all living and well. Two sisters died in infancy, cause unknown. In 1910, following an acute follicular tonsillitis, the patient suffered from a mild polyarthritis which even now occasionally manifested itself by fleeting joint pains. His habits were regular. He denied venereal infection. Triple typhoid inoculation had been performed, July 1, 1918.

Course of Illness.—July 20, the felon for which the patient was admitted to the hospital was incised. Because of a recurrence it was opened again, August 16. Roentgenoscopy at this time revealed some rarefaction of the distal phalanx but no outspoken evidences of osteomyelitis. No cultures were made.

August 19, the patient developed a typical follicular tonsillitis with its concomitant symptoms and a temperature of 100.3 F. From the crypts, *Streptococcus hemolyticus* was isolated.

August 20, there was a marked general improvement; the temperature was 99, the pulse 76, and the respiration 20. This encouraged us in the belief that the entire condition was a result of the tonsillar infection. That evening at 10 o'clock the patient had a severe chill lasting fifteen minutes, followed by a succession of chilly sensations. He complained of headache, generalized aching pains, and fever. His temperature was 105.2, pulse 94, and respiration 28. A general physical examination disclosed nothing other than the tonsillitis.

August 22, he complained of weakness, fever, malaise and general aching, more severe across the lumbar region. About midday a profuse nosebleed occurred which seemed to come from an erosion of the septum. There was nothing further on physical examination. In the morning the temperature was 104.8 F., with a pulse of 100, and respiration 32. It continued irregular throughout the day, falling to 100.4, with a pulse of 86 and respirations 24 in the evening. The white blood count was 10,200, with 76 per cent. polymorphonuclear cells, 14.5 per cent. small mononuclears, 7 per cent. large lymphocytes and 2.5 per cent. transitionals. The urine showed a trace of albumin, but otherwise was negative. Cultures were taken of the blood, urine and stool. From then on, the fever curve was irregular, ranging from 99.6 to 100.8, with a relatively slow pulse, from 78 to 104. No noteworthy changes occurred, however, until August 25.

August 25, the patient had another moderately profuse epistaxis, and complained of pain in the left side of the abdomen. The pain, not especially severe in its onset, continued as a steady, dull, dragging, pulling sensation, which at times became momentarily sharp and darting. It was most severe in the left flank, whence it radiated to the right iliac fossa and also to the lumbar region, where it took on the character of a severe lumbago. It passed from there down the posterior aspect of the left thigh as far as the knee. Examinations disclosed some changes. The face was flushed and the expression was bright but presented the appearance of one suffering from a severe intoxication. The left leg and thigh were semiflexed, extension exciting pain. The skin of the legs from the knees down, and likewise the forearms, was involved in a symmetrical erythema, over which areas were scattered a number of rose-colored, circinate lesions with a white center and a wheal-like periphery. They ranged in size from a split pea to a dime, were slightly elevated, and in most instances discrete and well defined. The lungs and heart were negative. The abdomen was a little distended and somewhat tense, but not rigid. Tenderness, not severe and rather diffuse, could be elicited only on pressure to the left of the umbilical area. Pressure and fist percussion over the lumbar muscles intensified the already present dull ache. The temperature, pulse and respiration in the morning were 104.8, 100 and 28, respectively, and in the afternoon 100, 78 and 24. In the evening it rose to 105.2, 104 and 30, following another severe chill. The leukocytes numbered 8,000, with 87 per cent. neutrophils, 2 per cent. basophils, 9 per cent. large lymphocytes and 2 per cent. small lymphocytes. The hemoglobin was 90 per cent. A single urine specimen showed some albumin and an occasional granular cast. The blood Wassermann test was negative, the Widal positive (the result of previous triple typhoid vaccination). The blood culture was negative for typhoid bacilli, but showed an easily recognizable *Streptococcus hemolyticus*. The stool culture was negative.

August 27, another chill occurred; but the symptoms and findings remained as described before, except that the muscular pains over the lumbar region became severe enough to require morphin.

August 28, the abdominal pain was marked, as was the pain in the lumbar region, which continued to radiate down the semiflexed left thigh. The patient's nutrition was still good, though the eyes were becoming glassy, the expression was listless, and the cheeks were sinking. The skin was dry and, though flushed, presented a brownish green, murky appearance. His sleep, which was almost constant, was interrupted by a low muttering delirium. The abdomen was distended as from a moderate degree of tympanites, but showed no dulness nor tumors, and only slight tenderness. The temperature continued irregular and the pulse relatively slow. The white blood count was 8,000 and the differential showed 52.5 per cent. neutrophils, 2 per cent. eosinophils, 11 per cent. large lymphocytes and 34.5 per cent. small mononuclears. The patient rested through the night under the influence of morphin.

August 29, at about 7 a. m., he awakened in a delirium with a temperature of 105.4, pulse 130, and respirations 32, complaining bitterly of pain in the back and the abdomen. His condition continued to become worse, and at 8 o'clock, at which time he was examined, he had sunk into coma. The eyes were glassy and white; the countenance was expressionless. The skin was ashen white, cold and clammy; the temperature was subnormal, the pulse small, weak and thready. The heart tones were slightly ringing in character, but weak and distant. The abdomen was much distended and tympanitic on percussion. No tenderness could be elicited. The patient died at 8:45 a. m.

Postmortem Examination.—External Appearance: The body was that of a well nourished, well built, young white man of approximately 183 pounds and 5 feet 10 inches long. Postmortem lividity and rigidity were present to a moderate degree. The skin was markedly blanched, but free from any lesions. The head was negative; the pupils were dilated and equal, and the teeth were in good repair. There was no palpable enlargement of any of the subcutaneous lymph nodes, and the genitalia were normal.

Body Cavities: The lungs and pleurae were normal. The heart musculature was pale and flabby; the valves were normal. The intestine was well distended and had a dry, pale appearance. With a single exception the parietal and visceral peritoneum was free from any gross lesions. In the right iliac region, on the under side of a loop of the midportion of the jejunum, agglutinating it to its supporting mesentery, was a small, circular, fibrinous exudate about 1 cm. in diameter which was surrounded by a zone of hyperemia. The intestine is separated with ease from the mesentery, and the lesion was found to involve merely the peritoneal coverings, though the bowel at this point presented a very small area of capillary congestion.

However, the greater part of the pathologic anatomy concerned itself with the condition and the position of the descending colon and the underlying hematoma. The hematoma, well confined retroperitoneally, extended from the brim of the pelvis on the left to the splenic flexure, and thence to a point in the epigastrium 4 cm. to the right of the median line in the region of the descending portion of the duodenum. It was pyramidal, each aspect, the medial and lateral, being covered by peritoneum, the separated folds of the mesocolon. The base measured 18 cm. in width. Along the entire summit the colon could be traced, having been raised a distance of 10 cm. from its normal position. The peritoneal covering of the bowel was stripped from the muscularis by the infiltrating blood tumor, which so enveloped it that only the anterior third of the circumference could be recognized.

Opening of the tumor revealed masses of clotted and some unclotted blood supported by the areolar and connective tissue it had infiltrated. The mesenteric veins and arteries were free from clots; the ascending and transverse portion of the large bowel was highly blood-stained, but otherwise free from tangible lesions. Over the pancreas external to its areolar tissue capsule the tissue was infiltrated with blood, and the peritoneal envelop of the duodenum presented an infiltration of blood under its surface. The fatty capsule of the left kidney had lost all semblance of its former self, appearing as a large, loosely gnarled mass of shredded fibrous and areolar tissue seeped in blood. In its meshes were embedded many dark red clots. Hematoma was formed from about 3,000 c.c. of blood.

On the mesial border of the left suprarenal in its anterior surface was a rent 1.5 cm. in length and 0.2 cm. in width running longitudinally. It extended through the cortex into the medulla, communicating with a small cavity 0.5 cm. in diameter. This cavity contained some liquid blood. On section the cortex about this area was blood-stained. No ruptured vessel could be found.

Microscopic Examination.—This in no way increased our knowledge as to the exact cause or origin of the hemorrhage. The medulla gave no evidence of containing more than the normal amount of blood. Between the rows of the cells of the cortex and along the paths of the afferent vessels were myriads of red blood cells, some in clusters, others distr[illegible] sparingly. [illegible] condition was most pronounced in [illegible] reticular [illegible]re the enmeshing reticulum was [illegible] loaded wit[illegible] [illegible] Th[illegible] [illegible]arenchymal cells were intact everywhere except those bordering on the margin of the small cavity. Here they showed some destruction.

The liver and the kidneys were pale and showed a moderate degree of cloudy swelling.

The spleen had the character of an acute splenic tumor.

RECURRENCE OF ORAL SYPHILITIC LESIONS DURING TREATMENT WITH MERCURY

REPORT OF THREE CASES *

G. O. SCOTT, M.D., C.M. (Ottawa, Ont.)
AND
G. H. J. PEARSON, B.A., M.D. (London, Ont.)
Captains, Canadian Army Medical Corps
ETCHINGHILL, KENT, ENGLAND

Recurrence of lesions of the skin and of the mucous membranes during the course of an attack of syphilis while the case is off treatment are not uncommon, approximately 3 per cent. of the admissions to the syphilitic clinic of this hospital being of this character. The most frequent form taken by lesions of this type is chancre redux. Another common form is the sore or sores occurring close to but not on the site of the original primary infection which, as McDonagh[1] states, are probably due to autoreinfection.

Besides the lesions recurring in connection with the original primary infection, whether on the penis or elsewhere, recurrent signs of generalization, such as skin rashes, mucous patches and condylomas, are by no means infrequent. The history obtained in such cases is usually that at some considerable time previously, six months to a year or longer, the patient has received the full War Office course of treatment, consisting of seven injections of arsphenamin, totaling 2.8 gm., and eight injections of mercury, the whole course covering fifty-six days, and since the completion of this course no further treatment has been received.

The purpose of the War Office treatment has been to heal the open lesions as quickly as possible in order that the man may be available for active service. Since, with the completion of this course, the man usually receives no further treatment, owing to the exigencies of the service, it is not to be wondered at that such recurrences manifest themselves, as our present knowledge of syphilis indicates that such a course of treatment is of itself inadequate to cure the disease. In the case of those patients in whom it is possible to follow for some time the course of the disease, interrupted courses of mercury and potassium iodid are given, which consist of three months' treatment followed by three months' rest, the whole covering a period of several years, depending on the severity of the case before treatment is commenced.

With this and possibly with further courses of arsphenamin, should these seem to be indicated, it was hoped that the patient would obtain a complete cure. The maximum amount of arsphenamin, however, to be given in the first year was not to exceed eleven injections, totaling 4.6 gm., given over a period of ninety-one days; and in no succeeding year were there to be more than four injections, totaling 1.8 gm., over a period of twenty-eight days. The reason for this limitation of dosage was the occurrence of a number of cases of jaundice when larger total dosage was used within this time interval. Such treatment quickly heals the open lesions and usually renders the Wassermann test negative; but three cases treated in this hospital in the past year seem to point to the fact that not only is it not curative, but it will not prevent the recurrence of open lesions, particularly in the mouth:

REPORT OF CASES

Case 1.—Private B. was exposed in April, 1917, and had an incubation period of three weeks. The case generalized before treatment was commenced, signs of generalization being a commencing macular rash. The patient was given one full War Office course of arsphenamin and mercury, followed by mercury by mouth for six weeks. There was no recurrence until Jan. 1, 1918. Examination on admission to this hospital on that date revealed the scar of the original primary lesion on the penis at the frenum. On the lateral margin of the tongue there was a papulo-ulcerative sore, the base of which was dirty and the sore itself markedly indurated. The submaxillary glands were considerably enlarged. The sore was negative for *Spirochaeta pallida*. The Wassermann test, January 22, was + + +. The patient was placed on a full course of neo-arsphenamin and mercury, which was completed, March 12. The Wassermann test, April 4, was + +. April 9, the patient was placed on three months of mercury and potassium iodid. While on this course, after he had received seven injections of mercury of 1 grain each at weekly intervals, he developed on the dorsal surface of the tongue multiple shallow ulcerations each about the size of a pea. At the junctions of the hard and soft palate there was a mucous patch about 1 inch in diameter. These lesions were positive for *Spirochaeta pallida*. The same day he received 0.6 gm. of neo-arsphenamin and 1 grain of mercury intramuscularly. The lesions healed immediately. Two months later he received 1 grain of mercury and three weeks afterward 0.6 gm. of neo-arsphenamin. Six weeks after this injection he developed an ulcer on the hard palate in which *Spirochaeta pallida* was not found. Three days later he received 0.45 gm. of neo-arsphenamin, but the lesion was very slow in healing. The following month he developed jaundice and now, three months later, the patient has no open lesions. Neurologically and serologically his cerebrospinal system is negative, but his blood Wassermann test is + + +.

Case 2.—Private L. contracted syphilis in 1917. The incubation period covered two weeks. His condition was primary when treatment was commenced. After treatment with seven doses of arsphenamin and eight intramuscular injections of mercury, the Wassermann test was negative. One year later the patient developed signs of cerebrospinal involvement, and the Wassermann test was found to be positive. He received three doses of arsphenamin and four intramuscular injections of mercury. He was admitted to this hospital a month later. Examination on admission revealed no signs of syphilis except the scar of the original chancre, which was situated on the ventral surface of prepuce; he also had a positive cerebrospinal fluid. He was placed on an interrupted course of neo-arsphenamin with a dosage of 0.45 gm. at weekly intervals, and four intramuscular injections of mercury with a dosage of 1 grain at weekly intervals. When he had completed this interrupted course, Aug. 8, 1918, the Wassermann reaction was +. Four days later he commenced a three months' course of mercury and potassium iodid. Eleven days after he had finished his eight weeks of mercury and while still on potassium iodid he developed a large ulcer, half an inch in diameter, at the lateral margin of his tongue and extending to both dorsal and ventral surfaces. The base of the ulcer was dirty. This lesion was positive for *Spirochaeta pallida*. The same day he was placed on another interrupted course of neo-arsphenamin and mercury, and the lesion rapidly healed. Other shallow ulcerations then appeared on his tongue and the margins of the gums which were negative for *Spirochaeta pallida* but positive for the organisms of Vincent's angina. These lesions extended till they involved the whole of the posterior half of the tongue, the fauces, the nasal and oral pharynx, the mucous membrane of the cheeks, the upper part of the esophagus and larynx, and the periosteum of the angles of the lower jaw. The general condition resulting from these gangrenous lesions caused the patient's death. Throughout the whole of his treatment at this hospital he was receiving intraspinal injections of arsphenaminized serum for his cerebrospinal condition. At necropsy the scar of the syphilitic lesion was plainly visible on his tongue. The pathologist's report on sections of the scar was: "The epithelium has entirely disappeared. The exposed surface is composed of fibrous tissue, scattered throughout which are many polymorphous cells. Beneath the fibrous tissue the muscle fibers show slight degeneration interspersed with areas of round cell infiltration."

[1] McDonagh: Biology and Treatment of Venereal Diseases, London, Harrison & Sons, 1915, p. 321.

CASE 3.—Private K. contracted syphilis in June, 1917, the incubation period being six weeks. He treated the primary sore himself by cauterization, but as it would not heal he was admitted to the hospital in August, 1917, with generalized syphilis. Examination on admission disclosed two sores situated on the prepuce, with no induration. The glands were all enlarged and hard. He had a faint macular rash over the trunk, limbs and forehead, and there was a mucous patch at the angle of the mouth. The Wassermann reaction was + + +. He was placed on a full course of arsphenamin and mercury. At the completion of this course the lesions had healed, and the Wassermann reaction was negative. In February, 1918, his blood was found to be + + and he was given an interrupted course of an arsphenamin preparation and mercury. The Wassermann reaction at the completion of this was negative; nevertheless he was given three months of mercury and potassium iodid. The Wassermann reaction was again negative at the completion of the treatment. After three months of rest the blood was +, and a month later the reaction was the same. He was placed on three months more of mercury and potassium iodid, of which one dose of mercury was taken by injection and the rest by mouth. Two months and a half of this course had been completed when the patient developed several shallow ulcerations and mucous patches on the tip and the ventral surface of the tongue. These lesions were positive for *Spirochaeta pallida*. The blood at this time was variable, being negative, January 6, + on the 9th, and + on the 16th. He was placed on an interrupted course of arsphenamin, and in a few days after the first injection the lesions healed.

COMMENT

Were it not for the demonstration of *Spirochaeta pallida* one would be inclined to look on these lesions as the herpetic ulcerations which Hutchinson[2] states are of common occurrence in the mouths of patients suffering from syphilis, but the finding of the organism definitely vouches for their specificity.

All three cases are similar in that the patients had received the routine War Office treatment and were all on mercury and potassium iodid when the lesions developed. The lesions did not develop at the site of former lesions, but were of the type that McDonagh[1] designates as autoreinfection. In two of the cases the general health of the patients was poor, but in the third case the general health was apparently good. In one case there was a mild mercurial stomatitis which later developed into a severe Vincent's infection, but all three were receiving careful dental treatment.

Akatsu and Noguchi[3] have demonstrated that *Spirochaeta pallida* increases its resistance to both arsphenamin and mercury in vitro. There is no reason why this cannot occur in vivo, and in these cases the resistance was increased against the mercury owing to its prolonged use, while the spirochete disappeared and the lesions healed as soon as the patient was placed on arsphenamin. There was no increased resistance against the latter substance, as the patients had all been a considerable time without treatment by it. In these cases it seems very probable that the mercury lowered the tone of the tissues of the mouth; and *Spirochaeta pallida*, being mercury fast, was given a fertile field in which to grow.

SUGGESTED MODIFICATION OF WAR OFFICE TREATMENT

While we would be among the first to recognize and record our appreciation of the good work accomplished by the British War Office in its careful study of the methods of treating syphilis and the service that has been accomplished in standardizing that treatment for the army, we know that the leader in this movement, Col. L. W. Harrison, D. S. O., is himself among the first to seek criticism and to welcome suggestions making for improvement in the methods employed.

The fact that under the present treatment such recurrences are to be encountered leads us to suggest that the routine War Office treatment be replaced by the following: During the first three weeks the patient should receive three injections of arsphenamin at weekly intervals with a total dosage of 1.2 gm. For the first eight weeks he should receive 8 grains of mercury, given in 1 grain doses at weekly intervals, and potassium iodid. For the next four weeks he should be given a tonic. When the month of rest has expired he should receive a small dose of arsphenamin and a week later a full dose, and for eight weeks mercury and potassium iodid, followed by four weeks' rest and tonics. The purpose of the small dose of arsphenamin preceding the full one is to prevent the occurrence of a dangerous Herxheimer reaction. This treatment might be continued indefinitely, though it would probably be better to give three months' complete rest in twenty-four. The object of this method would be to heal the open lesions by the first three injections. The purpose of the continued use of mercury and potassium iodid would be to carry on the sterilization of the host. Should the spirochete, however, become mercury fast the arsphenamin would be able to attack it while freely multiplying as the adult form. With this method of treatment, if carried on over a sufficient period of time, it should be possible to produce a complete cure of the disease with the minimum of danger to the patient and without recurrences similar to the cases cited.

Adequate Medical Service.—In these days of progress in preventive medicine there is some tendency to separate too sharply preventive from curative medicine. It should not be forgotten that an adequate medical service to the whole people will do more to prevent disease and disability than any other single measure to be considered. At present the people in the United States are paying out money sufficient for the maintenance of an adequate medical service, but fail to receive it. This money, however, is spent in such a haphazard manner that the service is not only often inadequate or worthless, but at times actually harmful. For one item—drugs—the United States spends $500,000,000 a year. This sum alone, if properly expended, would buy all the necessary drugs and add $2,000 a year to the income of e

ENTEROSTOMY AS AN EMERGENCY MEASURE

IN THE SURGICAL TREATMENT OF INTESTINAL OBSTRUCTION IN CASES OF GENERAL PERITONITIS FOLLOWING PURULENT APPENDICITIS

A. L. HAGEBOECK, M.D.
AND
L. H. KORNDER, M.D.
DAVENPORT, IOWA

Every surgeon experienced in the treatment of appendicitis knows that this protean disease presents itself in one of its most serious aspects when attended by a diffuse peritonitis with intestinal obstruction and distention of the abdomen. These complications often exist before the patient is brought for operation, but also frequently arise postoperatively in purulent ruptured cases. The disease now is peritonitis and no longer simply appendicitis. In this paper it is our purpose to call attention to some facts concerning the management and surgical treatment of such cases, as based on personal experience.

During the past four years, in association with Drs. Stoecks and Maxwell, we have operated in 200 cases of appendicitis. In this group of 200 cases all types of pathologic appendixes were represented. In a general classification, however, there were ninety-nine chronic cases, fifty-one acute, but well walled off, cases, and fifty acute, gangrenous and purulent cases, with general peritonitis and no walling off. It is with the last group of fifty cases that this paper concerns itself. The reason for so high a percentage (25) of peritonitic cases lies in the fact that all these patients came for operation from neighboring smaller communities, often arriving for surgical treatment as late as a week or ten days after the initial symptoms had developed. This fact itself is a potent illustration of the urgent need of surgical intervention in appendicitis as soon as the diagnosis has been made.

PRIMARY OPERATION AND SUBSEQUENT TREATMENT

As a usual operative measure, no attempt at removal of the gangrenous or ruptured appendix was made unless it was easily accessible and could be removed without much manipulation of the inflamed bowel. Whether, however, the appendix was removed or not, at this primary operation the sole aim was always to establish thorough drainage. Removal of the appendix was merely an incidental matter as compared with the main purpose of the operation, namely, to provide the most ample outlet for the discharge of pus from the inflamed visceral and parietal peritoneum. This was done by placing through the incision three or four rubber drainage tubes as deeply as possible into the abdomen, an additional one into the pelvis, and at least one through a stab wound into the most dependent portion of the abdominal cavity. The abdominal incision was never sutured but kept widely open with gauze packing. After the packing had been correctly placed, deep through and through silkworm sutures were made to prevent the wound from gaping. Thus the bowels were retained securely, while they remained within easy access from without and could be kept under constant observation.

This operative procedure constituted in its essentials our primary operation. The patients were now kept in Fowler's position, and for a period of from twenty-four to forty-eight hours they were given warm saline by the rectal drip method. This is never given continuously but intermittently in amounts varying from 4 to 6 ounces every three to four hours. The continuous method has been found unsatisfactory because of the pain and discomfort to the patient from too long continued retention of the rectal tube, and also on account of the difficulty experienced in keeping the saline at a sufficiently warm and even temperature. Because of the ease with which the gauze packing could be removed from the open wound, opportunities were offered to study the behavior of the small and large bowel. This proved of particular value in a number of cases in which, subsequent to the primary operation, intestinal paralysis resulting in marked abdominal distention developed. Here it was possible to observe the distended bowel become gangrenous and perforate. Perforation would commonly occur only in one loop of the bowel and very rarely in several.

RESULT OF THE DEVELOPMENT OF SPONTANEOUS FECAL FISTULAS

Gangrene and distention usually went together. They always preceded perforation. Wherever the distention was most pronounced and the gangrene had progressed the farthest, perforation would occur. But no sooner did a spontaneous perforation occur anywhere, either in the ileum or in the colon, than the distended bowel through this newly formed outlet evacuated much gas and a foul smelling, greenish fluid. This varied in amount from a few ounces to several pints in different cases. This briefly described picture was observed in ten cases out of the present group of fifty. They were cases that came late to operation and presented not only a ruptured or gangrenous appendix, but also, as a direct result, a generalized peritonitis. Out of this there then developed that twin picture, intestinal paralysis and abdominal distention.

All of these patients had a severe generalized peritonitis. The abdomen was distended and rigid, often so much so that the descriptive expression "drumlike" is no exaggeration. Uncontrollable vomiting existed in combination with almost complete, and often with absolute, obstipation. Enemas gave no relief. In every respect the patients presented pictures of extreme prostration. As soon, however, as a spontaneous fecal fistula developed and a thorough evacuation of the putrefied intestinal contents resulted, this picture of a moribund condition changed perceptibly and rapidly for the better. Vomiting ceased, the abdomen softened, and in a surprisingly short time patients that had appeared at the point of collapse gave hardly a sign of their former grave condition.

All of these patients recovered after draining freely for from three to seven weeks. As soon as drainage stopped, a secondary operation, the details of which will be considered later, was done, and soon afterward the patients were discharged cured.

During this time eleven similar cases had been seen in consultation after operation. In these cases there was a mortality of nine. All deaths were due to a general peritonitis and insufficient drainage from the wound. These cases were so serious and far advanced that any further surgical intervention seemed impossible. Here the ruptured or gangrenous appendix had been removed, the wound closed in the usual manner, and only a single drainage tube put in place. And again it was noticed that these patients suffered from a tremendously distended abdomen, drumlike rigidity of the abdominal wall, cyanotic lips, and very little discharge from the drainage tube.

These patients were pictures of acute suffering which finally ended in death. Yet the cases differed in no detail from ours until the time that the spontaneous fecal fistulas developed. No sooner, however, had the fecal fistulas developed, and the bowels evacuated their foul contents, than the course was the antithesis of death. Thorough and ample drainage was not the explanation for the recovery, because when the condition has progressed to the stage of complete obstruction and intestinal paralysis, there is no more discharge of pus and exudate from the peritoneum, and at this time no amount of drainage provided is of any avail. These recoveries must rather be ascribed to the perforation of the distended and gangrenous bowel. The development of spontaneous fecal fistulas is the primary cause of the improvement in the clinical course. This received strong support from the two cases seen in consultation in which the patients recovered, in both of which fecal fistulas also developed, and recovery dated from the time when such spontaneous perforation occurred. Out of the nine patients seen in consultation that died, one other did develop a fecal fistula; but since in this case insufficient drainage from the abdominal cavity had been provided, it also terminated in death.

As far, then, as the recovery of these patients of our own series is concerned, it must be considered as primarily due to the development of a fecal fistula which allowed the evacuation of a large amount of gas and foul smelling, greenish intestinal contents, and secondarily to the early provision for thorough drainage afterward. That the last mentioned point is also extremely important was forcibly brought to mind in the one case in which a fecal fistula developed, but drainage insufficient to carry off the foul intestinal contents and discharge from the peritoneum had been provided.

CONDITION WITHIN THE ABDOMINAL CAVITY

These experiences, with our own and with the consultation cases, led to serious thinking regarding the possible actual conditions existing within the bowel and abdominal cavity. In certain patients it was observed that the entire bowel was distended, and again in others only small portions seemed to be affected. At times small portions were found which were firmly angulated so as to form short loops of distended bowel that appeared to be almost completely cut off from the remaining flattened portion. Again in some instances no outward signs of angulation were discernible, and still only short loops of bowel were gangrenous or distended.

There seem to be three hypotheses to explain this condition: First, that angulation of portions or paralysis of the entire bowel is primarily due to mechanical obstruction resulting possibly from fibrinous adhesions. Second, that it is due to the laming of the smooth muscular fibers by infiltration of the intestinal wall with inflammatory products from the intensely inflamed peritoneum. And third, that it may possibly be a direct result of absorbed toxins having their effect on the central nervous system and causing a paresis of the muscular nervous peristaltic apparatus. But these are questions the settlement of which is not here attempted. However, we observed that small portions of the bowel, almost always the ileum and rarely the colon, would angulate and become firmly matted together, being at the same time distended and gangrenous. Again, intervening portions showed no such condition beyond that of an inflamed visceral peritoneum. One is tempted, therefore, to believe strongly that the central nervous system plays no causative rôle whatever, but rather that the entire series of events must be due to local causes. There may be a plain mechanical obstruction due to angulation of the bowel as a result of fibrinous adhesions between intestinal loops, or to a paralysis of the smooth muscle fibers in the intestinal wall as a result of the intense infection involving the mucosa of the alimentary tract as well as its entire serous surface.

Such being the case, why should the surgeon idly sit by and see whether the resistance and strength of the patient is sufficient to overcome this widespread infection? Does it not seem much more logical to open this infected bowel or such portions of it as are necessary, to provide a free outlet for the infected and foul intestinal contents? Since it is sound surgical treatment to open and drain any other portion of the human anatomy in which toxic material collects and threatens life, it certainly must also be considered sound here. All the more is it true if by so doing the patient is directly and almost immediately benefited.

ARTIFICIAL FECAL FISTULAS

This was the general policy adopted in the extreme treatment of the remaining cases of this group, and artificial fecal fistulas were made in seventeen cases.

Indications for doing an enterostomy, accordingly, have been, first, a drumlike distention of the abdomen associated with uncontrollable black vomiting, particularly when no relief is obtained by gastric lavage; second, the existence of complete obstipation which in no wise yielded to any enema (the pulse and temperature play only a very negligible part in deciding on an enterostomy; many times these fail entirely to indicate the seriousness of the patient's condition); third and most important and as the chief indication, any marked diminution in the amount of drainage from the wound.

If there is not a general improvement of the patient with the decrease in drainage, then the surgeon should be in readiness at any time to perform an enterostomy. As a result, the indications for doing this operation may be thus summed up: If the wound is better and the general condition of the patient is worse, enterostomy is imperative.

Our experience with these patients has shown that an anesthetic is not necessary for enterostomy. Since the abdominal wound, except for silkworm sutures, was left wide open, the bowel can be easily reached through this original incision. The one essential, absolutely necessary, is that the fistula be made into a distended or bulging portion of the bowel. Perforation of a collapsed portion of intestine is of no value. If no well formed wall of adhesions exists, the bulging loop of intestine is brought up to the incision and sutured with one or two silk sutures into the open wound, and then the enterostomy is performed. Immediately a rubber drainage tube is inserted and sutured with catgut into this opening. The drainage tube is allowed to remain in place until the sutures have been absorbed, when it is gradually withdrawn.

This is not a temporary perforation which is to be immediately repaired as soon as the gas and intestinal contents have escaped, but is meant to be a permanent fecal fistula. It remains such until it closes of its own accord or, failing to do this, until a future date when a complete secondary repair operation is done.

All of this can easily be accomplished without an anesthetic and with very little extra discomfort to the patient.

Usually the prostration is so severe that such pain as is caused by one or two sutures to tie the loop of bowel to the abdominal wound is hardly noticed.

It is conceivable that, owing to extensive fibrinous adhesions, complete strangulation of a loop of bowel might occur and result in only a partial evacuation of the foul intestinal contents. However, this contingency was never encountered in our cases. Perforation of a single loop of intestine was always sufficient to remove the obstructive features in these cases.

The cases of artificial fistulas behaved similarly to those formed spontaneously. As soon as a thorough evacuation of the foul contents of the bowel had occurred, a marked improvement in the condition resulted. The abdominal distention was no longer so marked. Black and fecal vomiting ceased almost immediately, and the extreme prostration gave way to a decided feeling of improvement. Patients that had a marked cyanosis, rapid pulse and high respiratory rate returned in a short time to a normal color, slower pulse and moderate breathing.

These enterostomies were allowed to become permanent fecal fistulas. Our idea was not to perforate the bowel momentarily and allow a temporary escape of gas and intestinal material and flora, but rather to provide drainage from the bowel itself until a time when the infection had been overcome and normal peristalsis again established. Therefore, if the fistula did not heal up spontaneously, it was a permanent affair lasting for three to four weeks, that is, until pus drainage ceased and a secondary repair operation could be done.

One objection that can readily be raised against the establishment of a permanent fecal fistula is that a secondary operation may become necessary. In view of the fact, however, that the secondary operation need not be done until the patient has regained his full strength, it can hardly be considered as a valid objection.

Furthermore, it does not always become necessary to close the bowel at the time of the secondary operation, because, if sufficient time elapses, nature often causes a spontaneous closure. In our present group of fifty cases, in twenty-seven of which there were either spontaneous or artificially induced fecal fistulas, seventeen healed spontaneously. In these at the time of the secondary operation it was only necessary to repair the original abdominal incision thoroughly. This is always done in order to prevent any possibility of a future ventral hernia. In only ten cases was it necessary to sew the intestine at the secondary operation. This was easily done when the opening in the bowel was large by a resection of a portion of it, an end to end or a lateral anastomosis being performed. This was necessary, however, in but two out of these ten cases. In the remaining eight we only had to close a small opening in the bowel by subserous sutures.

Out of this total group of fifty cases there were three deaths. Two of these occurred after the primary operation. Both patients had been brought to the hospital in a moribund condition and were operated on immediately, but died soon after the operation. The third patient, a boy of 6, recovered from the primary operation. At this time he had a ruptured purulent appendix, with no walling off whatever and a distribution of pus throughout the entire abdomen. During the night of the third day the patient rapidly developed a distended abdomen, all drainage stopped at once, and the patient became comatose. Our associate, Dr. Stoecks, immediately performed an enterostomy on two bulging loops of the ileum, but death followed soon. These three were the only deaths out of this series of fifty cases of acute appendical peritonitis.

Secondary operations were performed in forty-seven cases. This number includes those that had either a spontaneous or an artificially induced fecal fistula, and those remaining in which the ample drainage proved sufficient to overcome the infection in the peritoneum. In the primary operation of none of these were sutures used except for the deep silkworm sutures that were employed to prevent the abdominal incision from gaping too much. In the secondary operations not a single patient was lost, but all made uneventful recoveries. Most of these still come under our observation from time to time, and in none have any tendencies toward the development of ventral hernia been found.

COMMENT

While an enterostomy should not be done without due and sufficient cause, when the indications are once present, consideration of the annoyance and discomfort of a fecal fistula and the possible dangers of a secondary operation should not weigh heavily in the surgeon's mind. It should not prevent him from making use of this final means of saving the patient's life.

The value of an enterostomy in cases of this type was recognized years ago by the physiologist Heidenhain, who, according to our knowledge, was the first one to advocate the establishment of a fecal fistula as a remedial measure. In later years, Lund[1] of Boston advocated enterostomy as an extreme measure of last resort in selected cases in which the patients are practically moribund from septicemia. It is our contention, however, that the surgeon should never wait until a generalized septicemia from the absorption of intestinal toxins has occurred, but that the curative value of an enterostomy is secured only by performing this operation as early as possible.

Didactic discussions as to whether it is the intestinal obstruction and paralysis or the generalized septicemia resulting from it that kills is of little interest to the patient. What does interest him tremendously is that something be done that will afford him relief. This can be achieved only by removing the toxic intestinal contents. If gastric lavage fails to do this, and if drastic enemas likewise prove impotent, then the only other recourse is to make an artificial opening into the bowel. That a perforation of the bowel is not so dangerous to life as a failure to do this is illustrated in the present group of cases. Out of the entire number of patients that developed or had induced fecal fistulas, there was only one death, or a mortality of 3.7 per cent. We feel confident that this, too, could have been prevented had a fistulous opening been made somewhat earlier in the course.

With the treatment instituted in this group of fifty cases, there were three deaths, a mortality of 6 per

---

1. Lund, F. B.: The Value of Enterostomy in Selected Cases of Peritonitis, J. A. M. A. 41:74 (July 11) 1903.

cent. This should be compared with a report of from 30 to 40 per cent. mortality in similar cases as reported by Kelly in 2,000 cases at Mount Sinai Hospital or with nine deaths out of eleven cases, a percentage of 80, seen in consultation by us.

CONCLUSION

In the treatment of this type of appendicitis, it is of paramount importance to establish free drainage in order to encourage the discharge of pus and infective fluids from the abdominal cavity. If this is insufficient, and drainage ceases owing to a dry peritonitis so common in intestinal obstruction and paralysis, then the latter must be relieved by the performance of an enterostomy. It is our conviction that it is not the appendicitis or even the peritonitis, per se, that kills, but rather that it is the toxins which these have caused to accumulate in a gangrenous and paralyzed bowel. Relieve that, and the reward will be the restoration of life and health to the patient in a large percentage of so-called hopeless cases.

INCREASED TOLERANCE AND WITHDRAWAL PHENOMENA IN CHRONIC MORPHINISM

A REVIEW OF THE LITERATURE *

A. G. DuMEZ, PH.D.
WASHINGTON, D. C.

It is well known that individuals addicted to the use of opium, morphin, codein (Bouma,[1] Pelz[2]) or heroin (Fauntleroy,[3] Wholey[4]) are able to withstand enormous doses of these drugs — many times as large as the lethal dose for individuals unaccustomed to their use. In fact, the average daily oral dose of morphin for an addict is stated to be from 8.22 grains (Brown[5]) to 15.3 grains (McIver and Price[6]), while the daily consumption in certain cases has been reported to be as high as 90 grains (McIver and Price[6]) and 248 grains (Hinckley[7]). It has also been established that, when the administration of these drugs is discontinued in the case of individuals habituated to their use, definite withdrawal symptoms manifest themselves: In general, there is restlessness and a sense of depression in the beginning, followed by yawning, sneezing, lacrimation, coughing, retching and vomiting. Later, there is pain in the abdomen and lower extremities, diarrhea, profuse perspiration, tachycardia, marked asthenia, and irregular pulse, the latter going from extremes of slowness to extremes of rapidity. There may be complete exhaustion and finally collapse, in some cases death.

CAUSES OF INCREASED TOLERANCE

In order to explain the mechanism of the increased tolerance of the system for these drugs and the appearance of the withdrawal phenomena on the discontinuance of their use, a number of investigators have carried out experiments with animals. In general, these researches have shown that tolerance[8] can be induced in such warm-blooded animals as dogs (Faust[9] and others), goats, rabbits, rats and pigeons (Cloetta,[10] Morgenroth[11] and others), whereas cold-blooded animals like the frog become more susceptible (Hausmann[12]). In the case of animals, this tolerance persists for only a few days, while in human beings, it may continue for months (Bishop[13]). The theories evolved by the different investigators in explanation of these findings are both numerous and varied.

In 1883, Marmé[14] conducted a series of experiments with dogs, and concluded, from the results obtained, that morphin was converted in the body into oxydimorphin,[15] a substance having a diametrically opposite physiologic action to that of morphin. He contended that this substance produced the abstinence symptoms which make their appearance on withdrawal of the drug; required increasing amounts of morphin to neutralize its effects; and in turn neutralized the morphin, thus accounting for the increase in tolerance. This theory, however, appears to be untenable in view of the fact that Donath,[16] Stark[17] and Marquis,[18] respectively, operating under similar conditions, could not identify oxydimorphin in either the blood or urine of dogs in which tolerance to morphin had been established. Furthermore, it has been shown that oxydimorphin prepared from morphin with the aid of certain plant juices (Bougault[19]) or by the action of various oxidizing agents in alkaline solution (Schutzenberger,[20] Nadler,[21] Polstorff[22]) does not possess the properties assigned to it by Marmé. Magendie[23] found it to be inactive when administered by mouth to dogs in doses of 0.36 grain, while Kreis[24] observed that it had a very weak morphin-like action. When given intravenously, the latter found that it produced weakness which soon developed into stupor. Toth[25] found

it to be inactive when administered by mouth or subcutaneously. He attributed the effects observed by Marmé to emboli, formed, in his opinion, as a result of precipitation which occurred when oxydimorphin was injected into the blood stream. Additional investigations demonstrating the relative inactivity of oxydimorphin and the erroneousness of Marmé's conclusions have been reported by Kobert,[26] Diederich,[27] Puschmann[28] and Gioffredi.[29]

A theory which appears more plausible and which has acquired a certain degree of acceptance was advanced by Faust[9] in 1900. From his investigations, he was led to the conclusion that the system in the case of dogs acquires the power to destroy increasingly large amounts of morphin. He was able to recover from the feces 66 per cent. of the initial dose administered hypodermically. In the feces of the twenty-first to twenty-fourth days of administration, he recovered only 26 per cent.; from the twenty-ninth to the thirty-second days, 8 per cent.; from the thirty-sixth to the fortieth days, 4 per cent., and later, none at all, even though the quantity administered was fifty times as great as that given in the beginning. These dogs, according to his account, showed the same symptoms of chronic morphinism as manifest themselves in man. They showed signs of uneasiness for the drug, became very restless when the time for injection drew near, and one dog is reported as having given every sign of satisfaction when the needle was introduced. As the organs of these animals after death were found to contain only very small quantities of morphin, Faust concluded that tolerance was established solely through the increased power of the organism to destroy (oxidize) morphin.[30]

DESTRUCTION OF MORPHIN IN THE BODY

That morphin is destroyed to some extent in the living organism, there is no apparent reason for doubting. That it is destroyed in increasingly large amounts during the course of tolerance is a contention supported by considerable evidence. Thus, Albanese[31] observed that the livers of tolerant dogs possessed the property of destroying relatively large amounts of morphin in vitro if the animals were deprived of the drug for three or four days preceding death, and that the destructive power was commensurate with the degree of tolerance that had been established. Dorlencourt[32] duplicated these experiments and reported similar results. Cloetta[10] and Babel,[33] respectively, found that morphin was also destroyed in vitro by brain pulp, and to a lesser degree by the tissues of other organs. The experiments of Langer[34] with heroin also have a bearing in this connection. In working with dogs, he found that heroin was excreted principally in the urine, although a small amount also appeared in the feces. During the course of tolerance, he observed that the amount in the urine became less and less, so that finally none could be detected in either the urine or feces.

Even though we accept the foregoing contention, that the organism during the course of tolerance acquires the power to destroy increasingly large amounts of morphin, as an established fact, it does not necessarily follow that this condition is a causative factor in the production of tolerance. It may only be a concomitant phenomenon. In fact, this is the opinion of Cloetta, whose theory in explanation of the mechanism of acquired tolerance was published in 1903.

TOLERANCE OF THE BRAIN FOR MORPHIN

Cloetta appears to have been impressed with the fact that the brain rapidly develops a tolerance for morphin in comparison with the other organs of the body. In search for an explanation of this condition, he conducted a series of experiments in vitro in which he attempted to determine the relative fixing powers of the tissues of the different organs for the alkaloid. The results obtained showed that the brain tissues possessed this power to the greatest degree. He therefore concluded that, while morphin might eventually be destroyed in the organism, its destruction was not the cause for the development of tolerance, but merely a result consequent to its fixation by the tissues. According to his ideas, increased tolerance is to be attributed to an increased power of resistance of the protoplasm to the action of morphin. In the case of the brain, which acquires tolerance comparatively rapidly, it is to be attributed to an increase in power of the lipoids to absorb the drug. In this connection, attention is directed to the fact that Bieberfeld[35] could detect no quantitative changes in the lipoids of the brain of a dog that had acquired a tolerance for ten times the lethal dose of morphin.

DESTRUCTION OF MORPHIN AS CAUSE FOR ESTABLISHMENT OF TOLERANCE

The question of the destruction of morphin in the system as far as its being the sole cause for the establishment of tolerance appears to have been definitely settled by Rübsamen[36] in 1908. In experimenting with rats, he observed that animals of this species which had been immunized to large quantities of the drug, and which could withstand double the lethal dose with impunity, showed at a given moment the presence in their bodies of sufficient morphin to produce toxic effects in animals that had not previously received the drug. He therefore advanced the theory that, in addition to the increased power of the organism to destroy morphin, the cells of the tissues, during the period of increasing tolerance, become less sensitive to the action of the drug. This theory has been accepted in principle and further elaborated by van Egmond[37] and by van Dongen.[38]

30. Faust's results are not conclusive evidence of the destruction of morphin in the system as he did not make quantitative determinations of the amount execreted in the urine throughout the course of his experiments. It is possible that the path of elimination changes during the period of increasing tolerance. In fact, considerable support to this view is given by the observations made by von Kaufmann-Asser (Ueber die Ausscheidung des Morphins im Harn, Biochem. Ztschr. **54**: 161-173, 1913). The latter found that rabbits excreted in the urine from 3 to 23 per cent. of morphin in acute poisoning, and up to 39 per cent. in chronic poisoning.

Van Egmond in his experiments (1911) demonstrated that the responsiveness of the vagus center to morphin remains unaltered. In tolerant dogs in which the brain cortex and vomiting center failed to respond to 100 times the initially active dose (0.23 gm. per kilogram of body weight), the vagus center showed the effects of minute doses (0.04 mg. per kilogram of body weight) of morphin as long as several hours after its administration. Van Dongen, in 1915, found that it was possible to accustom the respiratory center to morphin in quantities as large as 1,800 times the initial dose to which the breathing function was responsive, and that the nervous centers governing the dilatation of the pupils were also immunized to the action of the drug in dogs habituated to its use. Other centers did not appear to be so easily affected.[39] The gastric manifestations, for instance, were not so readily dispelled by the development of a general tolerance. Furthermore, the time within which these centers lose their sensitiveness does not correspond with their comparative sensitiveness to the drug before tolerance is established. Van Egmond states that his observations compel him to accept the theory of Rübsamen in preference to that of Faust as more nearly approaching the truth, while van Dongen concludes that we must further postulate a specific tissue immunity in which the different organs and centers acquire immunity with a varied readiness and to an unequal degree.

ANALOGY BETWEEN IMMUNITY BY VACCINES AND THAT OF OPIUM

An explanation of an entirely different character has resulted from the researches of another group of laboratory workers. These investigators have attempted to show an analogy between the immunity produced by bacterial vaccines and that of opium or its alkaloids. As pioneer work along this line should be mentioned that of Gioffredi[40] reported in 1897.

Gioffredi prepared a serum from dogs that had become tolerant to large doses of morphin, and found that, when this serum was injected into kittens, it protected them against the fatal effects of from two to two and one-half times the minimum lethal dose. From this, he concluded that an antitoxic substance ("antimorphin") was formed in the blood of tolerant animals and that this neutralized the effects of the morphin. Results pointing to a similar conclusion were obtained by Hirschlaff,[41] von Marikovszky[42] and by Berri and Belgrano.[43]

In 1902, Hirschlaff reported that he had prepared a serum from rabbits that had acquired a tolerance for relatively large doses of morphin, and that this serum, when injected into mice, protected them against three or four times the minimum lethal dose of the drug.

Von Marikovszky (1907) found that, when from 0.035 to 0.049 grain of morphin detoxicated with progressively diminishing amount of potassium permanganate was administered every three days to rabbits, these animals acquired a high degree of tolerance. A serum prepared from these tolerant animals is stated to have retarded and, in some cases, to have prevented death when injected with or immediately following an otherwise fatal dose of the alkaloid.

Berri and Belgrano (1912) induced tolerance in a somewhat different manner. They injected rabbits repeatedly with an "aggressin-like" centrifugal pleural exudate produced by morphin and aleuronate. A serum prepared from these animals is also reported to have possessed immunizing properties, and probably antiaggressin properties as well.

An opinion favoring a theory of this nature has also been arrived at by Bishop (1913) and others through clinical observations. On the other hand, the animal experiments of Morgenroth (1903), Cloetta (1903) and Mirto[44] (1905) all show concordantly negative results with respect to the demonstration of an antibody in chronic experimental morphin poisoning.

The contradictory character of the results obtained by the foregoing investigators tends to place a negative value on any theory in which it is necessary to assume the direct action of an antibody. Nevertheless, there appear to be good reasons for the belief in some form of serum immunity—perhaps of the second order as described by Ehrlich. For example, Ferrai[45] (1909) demonstrated that morphin differs from most other alkaloids in that it possesses an anticomplementary power. He observed that morphin hydrochlorid, sulphate or acetate hindered hemolysis in the hemolytic system, guinea-pig complement plus rabbit immune amboceptor acting on sheep's blood plus the erythrocytes of sheep's blood.

TOXIN THEORY OF PETTEY

Still another theory differing in character from any of the foregoing has been brought forward by Pettey[46] (1913). As a result of clinical studies, he arrived at the conclusion that the repeated use of opium or its alkaloids gives rise to the formation of toxins (of autogenous and intestinal origin) which act as irritants to the nerve tissues, and that increasingly large amounts of morphin are necessary to counteract the effect produced. This explanation is concurred in by Wholey (1912), who states that he believes increased tolerance, in part at least, is due to the fact that the nerve cells become exhausted from continued reaction and the accumulation of waste products, and for these reasons require an increased dosage to bring about an adequate effect.

WITHDRAWAL PHENOMENA

Important as these theories may be for an understanding of the altered physiologic conditions produced during the course of tolerance, the majority of them offer no explanation for the additional feature that must be taken into account in practice, namely, the abstinence phenomena that manifest themselves when the drug is withdrawn. These symptoms are not merely of a negative nature, but are of the positive kind described in the fore part of this paper.

It will be recalled that Marmé assigned as a cause for the appearance of the abstinence symptoms the physiologic action of oxydimorphin. This substance, he contended, was formed from morphin in the body and required the administration of additional amounts of the latter to counteract the effects that it produced. His theory, however, is held to be untenable for reasons already presented. That, however, these phenomena are due to the formation of some unidentified toxic substance in the body appears to be highly probable in the light of the comparatively recent discoveries of Valenti.[47]

---

[39] Langer (1912) observed, in the case of heroin, that the acquired tolerance of dogs to its narcotic action did not extend to its convulsive effects.

[46] Pettey, G. E.: The Narcotic Drug Diseases and Allied Ailments, Philadelphia, 1913, p. 13.

In 1914, Valenti found that, when the administration of morphin was stopped in the case of dogs after a period of developing immunity, marked circulatory disturbances made their appearance. These consisted of increased frequency of the pulse, severe arrhythmias, and arterial hypotension. These promptly disappeared if morphin was again administered in quantities sufficient to produce the so-called morphin pulse. When the serum of these dogs, taken during the abstinence period, was injected into normal animals of the same species, the foregoing syndrome was promptly produced. This was demonstrated not to be due to the toxic properties of the serum as such, since no evil effects were observed when the serum from unmorphinized dogs was employed.

While the identity of this toxic substance has not been established to date, it is not in keeping with our present theories of immunity to pronounce it an antitoxin. In no disease in which antitoxin formation has been demonstrated have there been observed untoward symptoms that could be attributed to the action of the antitoxin. Although aware of these facts, Bishop still persists in the opinion that this substance is an antibody which also possesses toxic properties. His theory in explanation of increased tolerance and the appearance of the withdrawal phenomena is based on this belief and is supported by logical deductions made from a clinical study of numerous so-called addicts.

A theory also based on the assumption that toxins are responsible for the symptoms produced was brought forward by Pettey in 1913. He contends that the withdrawal phenomena are the result of the saturation of the system with toxins of intestinal and autogenous origin. So long as the drug is taken in the required amount at regular intervals, the nerve centers are kept benumbed so that they do not respond to the irritating action of the accumulated toxins; but when administration is discontinued, the characteristic symptoms immediately manifest themselves.

An explanation somewhat similar in type was advanced by Kunkel[48] in 1901. He assumed that the cells of the various organs were spurred to greater efforts under the continuous effects of repeated doses of morphin, and that when the depressing action of the drug was removed through the discontinuance of its use, a hypernormal activity resulted. In his opinion, the withdrawal symptoms are merely the outward manifestations of this increase in activity.

CONCLUSION

From the foregoing review of the literature, it becomes apparent that, up to the present time, all investigators have failed to demonstrate the exact nature of the factors that enable the system, in the case of either animals or human beings, to tolerate enormous doses of these drugs or to identify the substances that give rise to the withdrawal phenomena. The only knowledge of a positive nature that we really have at present concerning these problems is that the different organs and centers of the body acquire tolerance to morphin and heroin to a different degree and with varied degrees of readiness; that these drugs as such are excreted in the feces in diminishing amounts during the period of acquiring tolerance; and that there is evidently present in the blood serum of tolerant animals (dogs) during periods of abstinence a substance or substances which, when injected into normal animals of the same species, causes the appearance of symptoms identical with the so-called withdrawal phenomena. Whether or not the disappearance of these drugs from the feces is due to their increased destruction in the organism is still an unsettled question. Attempts to solve this problem through a chemical examination of the excretions have led only to confusion, the literature being replete with contradictory results. Furthermore, it has not been proved that the destruction of morphin in the organism, if it does take place to an increased degree, is a causative factor in the production of tolerance. As stated before, it may be only a concomitant phenomenon.

TORSION OF AN ENLARGED HYDATID OF MORGAGNI

AS THE CAUSE OF ACUTE ABDOMINAL DISTURBANCE *

CHESTER H. WATERS, M.D.
OMAHA

The occurrence of a small cyst with a stringlike pedicle, having its attachment to the lower margin of the fimbriated extremity of the fallopian tube, is frequently observed. These are generally considered as derived from some persistent remnant of the wolffian body or its duct, and their presence has little pathologic or other significance.

As a perusal of the available literature has been most unfruitful in bringing to light evidence of their possible pathologic importance, an instance that recently came under my observation may be of interest in showing that a cyst of this character, by virtue of its long, attenuated pedicle, may be subjected to torsion and give rise to acute abdominal disturbance of unusual severity.

REPORT OF CASE

History.—Miss E., aged 18, domestic, who first consulted me, Feb. 5, 1918, on the preceding day had been rather abruptly seized with cramping pains in the lower abdomen especially on the left side. Accompanying the pain there was unusually severe and repeated vomiting and extreme prostration.

Examination.—The temperature was 101, the pulse, 130. The abdomen was rounded, moderately tympanitic with tenderness on pressure, most marked in the left hypogastric region. There were spasm and *moderate rigidity* of the rectus on this side. Rectal examination was negative, except that tenderness was elicited high up on the left side. A leukocytosis of 16,800 with a polymorphonuclear percentage of 86 was found. *Urinalysis was negative.*

[48] Kunkel, A. J.: Handbuch der Toxikologie, Jena **1**, Part 2, pp. 815-826, 1901.

* From the Surgical and Pathological Departments of the University of Nebraska College of Medicine.

Diagnosis.—The past history did not furnish much enlightenment and was rather confusing. The patient had never been rugged since puberty, and menstruation had always been extremely painful and profuse. During the preceding nine months the interval had been reduced from four to three weeks, and the dysmenorrhea exaggerated. The onset of the irregularity followed an attack similar to the present one, and was definitely caused by falling heavily when attempting to jump over a ditch. Since then, at intervals of two or three months, similar though milder attacks had occurred, lasting only a few days.

She denied the possibility of venereal infection, and this assertion was substantiated by the presence of an intact hymen. In view of the pronounced gastric manifestations, the fever and rapidity of the pulse, together with the fairly well localized pain and associated muscular spasm and rigidity, the possibility of involvement of a left sided appendix was entertained.

Torsion, rupture or hemorrhage from or into an ovarian cyst were also considered as possible diagnoses.

Course.—As the diagnosis was in doubt, the rather hazardous course of temporization under close observation was decided on. During the following five days the temperature ranged from 99 to 100, while the pulse rate remained rather consistently around 100. Some nausea persisted, as did an area of localized tenderness of some intensity in the left hypogastrium. As there was no appreciable improvement in the symptoms, operation was decided on.

Operation and Result.—February 11, a median laparatomy incision was made below the umbilicus. A small amount of blood-tinged serous fluid was found in the pelvis. At the outer extremity of the left tube a large hydatid of Morgagni was discovered which approximated, in size and shape, a large olive. It was purplish black and had a pedicle 1½ inches long. A twist of one complete turn was noted in this when the structure was elevated, but it may be assumed that a greater degree of torsion may have existed and that partial unwinding had occurred spontaneously or as a result of exploratory manipulation in the pelvis. The cyst was quite tense, and over its surface were numerous engorged veins. The pedicle was ligated and the cyst removed. Both ovaries were found enlarged, owing to numerous atretic follicles. Both ovaries were partially resected, and an appendix, in the usual situation and otherwise normal, was removed. The abdominal cavity was carefully explored and no other pathologic condition found. The operation was completed with a dilatation of the cervix. Convalescence was uneventful. Subsequent menses have been regular and practically without discomfort. The patient's general health improved markedly, and she gained 10 pounds in five weeks. The cyst was oval, dark purple, and measured 2.5 by 2 cm. The remnant of its pedicle was 2.5 cm. long.

CONCLUSION

I simply wish to add torsion of the pedicle of an enlarged hydatid of Morgagni, which is an otherwise harmless structure, to the list of unusual causes of acute abdominal disturbance occurring in the female.

Feeblemindedness.—The report of the Kansas Commission on Provision for the Feebleminded, dated Jan. 1, 1919, says that, based on the lowest conservative estimate, there are 7,500 feebleminded persons in Kansas, and less than one tenth of them are cared for at the institution at Winfield. It is also estimated that there are at least 1,500 feebleminded children in the public schools of the state, where they are not receiving the type of training that will fit them to be partly self-supporting. It is recommended that the way to stop the increase of the feebleminded is to transfer them to the custodial care of the state before they reach the age of adolescence, and also to place the feebleminded men and women of the state in colonies especially provided for their care. The report contains discussions of various aspects of the problem of the feebleminded, and offers a program for handling it.

Clinical Notes, Suggestions, and New Instruments

REPORT OF AN UNUSUAL CASE OF BACTEREMIA

H. H. Chamberlin, M.D. (Glendora, Calif.), and A. J. Minaker, M.D.
Lieutenants, M. C., U. S. N. R. F.
San Francisco

A. J. L., aged 18, who had a neurotic temperament, reported, Sept. 14, 1918, complaining of vertigo when up and about. The previous personal and family history was negative. Examination disclosed a slightly enlarged spleen and prolonged expiration over a small area under the right clavicle. The temperature was 104 F., the pulse 108, and the white blood count 23,000. There were 85 per cent. polymorphonuclears. No plasmodia were found in the blood, and the blood culture was sterile.

During the first two weeks the temperature ran a very irregular course, ranging from 97 to 104 F., without sweats. Typhoid fever, malaria and tuberculosis were eliminated, as the possible underlying conditions by appropriate clinical and laboratory findings. Two blood cultures made during this period produced no growth.

A blood culture, September 29, produced a gram-negative diplococcus, which was plated on eosin brilliant green, blood agar, nutrient agar and litmus lactose agar. No growth developed on any of these mediums except the blood agar, which produced an abundant growth of pure gram-negative diplococci. These organisms varied in size, shape and staining characteristics. Fifty c.c. of antimeningococcic serum were administered intravenously at this time.

TITRATION AGAINST DILUTED SERUMS

	Dilutions			
	1:50	1:100	1:200	1:400
Patient's blood	+++	+++	++	+
Rockefeller polyvalent	++	++	+	—
Rockefeller regular type	+	—	—	—
Rockefeller para type	++	++	+	+

By the Krumwiede method of slide agglutination, a pronounced clumping occurred with the Rockefeller polyvalent serum. This clumping occurred in gradually diminishing intensity as the culture was attenuated by subculturing.

Subcultures were made on plates with these results: nutrient agar, —; serum glucose, + (with slight acidification); serum maltose agar, +; serum levulose agar, —; blood agar, +. There was no growth on plates of various mediums left at ordinary room temperature. Andrade's indicator was used for determining acidification in the serum agar tubes.

An emulsion of the growth from the serum agar was standardized at about 5 billion to the cubic centimeter. This was titrated against diluted serums as shown in the accompanying table.

October 2, the patient developed an exaggerated knee jerk, and ankle and patellar clonus. Kernig and Babinski reactions were absent. The temperature was 103 F., the pulse 136, and the respiration 19. Twenty c.c. of spinal fluid were withdrawn and 30 c.c. of antimeningococcic serum were injected into the spinal canal. The fluid withdrawn was sterile, the cell count was 20 per cubic centimeter, and the globulin test was negative. For two days the condition of the patient was much improved.

During the next ten days about 300 c.c. of various makes of antimeningococcic serum were given into the veins, muscles and spinal canal, none of which produced the slightest benefit. The temperature ranged from 97 to 103.4 F., and the pulse remained above 110.

October 16, a blood culture was sterile, and 0.3 c.c. of an autogenous vaccine, containing about 1 billion organisms to the cubic centimeter, was given intramuscularly. This was followed by a slight reaction and reduction of the temperature. The vaccine was repeated at forty-eight hour intervals, the dosage being rapidly increased up to 1.25 c.c. This was reduced to 1 c.c. and was continued up to November 4. The temperature remained normal after October 31. There was a remarkable absence of subjective symptoms throughout the course of the disease. Vertigo was the only symptom complained of and it was with difficulty that the patient was kept in bed.

Convalescence was uneventful and rapid, though the pulse remained above normal up to the last of December.

SUMMARY

The interesting features of the case are: (1) The absence of subjective symptoms; (2) the presence in the blood stream of an organism of this type without production of more pronounced meningeal symptoms; (3) the slight reaction of the organism on the carbohydrates, its irregular agglutination reactions, and the absence of its specific antibody in all of the serums employed, and (4) the prompt reaction of the patient to the autogenous vaccine.

The conclusion reached by us and concurred in by Dr. K. F. Meyer of the Hooper Foundation, San Francisco, was that the infecting organism was a parameningococcus.

COLORIMETRIC STANDARDIZATION OF THE CELL SUSPENSION IN THE WASSERMANN REACTION

Rawson J. Pickard, M.D., San Diego, Calif.

Of the five factors entering into a complement fixation reaction, such as the Wassermann, one of the most important to standardize is the amount of cells to be hemolyzed. On this quantity, the erythrocytic mass, is based the amount of hemolytic amboceptor to be used, and from these the quantity of complement is derived by titration. The preliminary titration of the amboceptor-complement balance required for hemolysis determines the quantity of complement which may be fixed by an antibody contained in the serum used in the main test. Variations, therefore, in the quantity of cells to be hemolyzed directly affect the diagnostic value of the fixation reaction.

This is not true of a "loose system" when only strong positives are sought, in which many units of both complement and of amboceptor prevent the possibility of fixation from anything less than an overwhelming amount of antibody. In such tests delicacy in the preliminary titrations can be greatly diminished.

At present there is a source of confusion in that many laboratories are using as controls, or even substituting for the Wassermann reaction, various modifications of the test which are not only more sensitive to complement fixing bodies but also do not use the same proportions of the different factors, and in using different factors give results not wholly comparable to the Wassermann, the basis of diagnosis being altered. It is time that efforts were directed toward standardizing the reaction or such elements of it as can be standardized, for one reason, in order to allow definite comparison of the ever multiplying modifications.

The hemolytic system used, whether sheep, ox, human or chicken, is important only as it affects amboceptor, for the amount of cells and of complement is readily made the same for different workers. An amboceptor of less than 1:1,000 titer is in danger of giving complement fixation from agglutinin reactions, and an erythrocyte to be usable must not only be accessible when wanted but capable of producing a high titer hemolytic amboceptor in an available animal. The use of cell suspensions of 1, 2.5, 3.5 or 10 per cent. in different technics makes ultimately for a different standard of antibody content in the serum to be tested for the diagnostic amount of fixation, unless the amount of cell suspension used gives the same proportion of cells to the whole volume of the main test. The original standard of one-fifth volume of 5 per cent. cells makes 1 per cent. cells in the total volume, and should be adhered to.

The cell suspension is usually estimated from the quantity of sediment in the centrifuge tube after the last washing. This procedure is not the best for several reasons: The arm length of the centrifuge, its speed and the time of centrifugation should all be accurately measured. Inaccuracies in the lower graduations of the centrifuge tube are common. The reading of the mass of sediment is a question of judgment unless it happens level with a marking. Sometimes even after repeated washings there is a little sediment adherent to the tube. The saline solutions in different laboratories vary between 0.8 and 0.9 per cent. Altogether there are too many details to be left to the average technician.

In the Sahli hemoglobinometer is furnished a method for obtaining a cell suspension everywhere of the same strength. The instrument is in every laboratory, readings are quickly made, and the percentage of error is far less than in the estimation from sediment. The complement will be found to titrate more evenly. Of a 5 per cent. suspension of sheep cells properly centrifugated, 0.2 c.c. will give a reading of 75 in the Sahli hemoglobinometer. With this method the suspension need not be wholly thrown down after the last washing (4-5); a reading can be made with the hemoglobinometer, and the final dilution may be estimated and made quickly and accurately, and in all laboratories of the same strength.

COINCIDENTAL ACUTE PERFORATION OF A DUODENAL ULCER, AND BLOCKING OF THE CYSTIC DUCT BY STONE, WITH ACUTE CHOLECYSTITIS

J. R. Buchbinder, M.D., Chicago
Associate in Surgery, Northwestern University Medical School

An acute free perforation of a duodenal ulcer presents a picture that should seldom confuse it with the more common of the abdominal lesions. The sudden and usually terrific onslaught of pain which drops the patient as though shot, the bilateral boardlike rigidity, and the complete physical collapse that accompany the accident, usually serve clearly to define its nature.

Obviously, the chief concern of the surgeon in the case of the acute abdomen is to decide the necessity for surgical intervention. This done, a differential diagnosis should, if possible, be made. In the case I wish to report, the interest centers about two interesting conditions: First, there were two coincidental acute lesions, both in the upper abdomen; second, the clinical picture suggested neither of the two lesions.

REPORT OF CASE

History.—Mrs. P., aged 29, who entered Wesley Memorial Hospital, September 21, 1918, referred by Dr. J. G. Campbell, began first to feel sick shortly after noon, September 19. Previous to this time she felt "perfectly well." As the afternoon progressed, the vague feeling of illness defined itself as a diffuse abdominal discomfort which progressed in severity, keeping her awake until midnight, after which she slept at intervals.

On the following morning, feeling somewhat relieved, she was able to be about. Late in the afternoon a rapid increase in the severity of the pain compelled her to go to bed. Attempting to eat supper, she vomited for the first time since the onset of symptoms, thirty hours previous. During the night, the pain shifted to the right side, and became so severe that at 4 a. m. her physician was called in. A possible history of previous abdominal disturbances was minutely investigated, and proved negative.

Examination.—The patient was first seen by me forty-eight hours after the onset of symptoms. Her general condition was good. There was no evidence of shock. She was suffering what evidently was an easily endurable abdominal pain. There was marked rigidity over the entire right rectus; the appendical area was very tender. There was moderate tenderness over the gallbladder region and in the midline just below the ensiform. The left rectus was moderately rigid. At this time the leukocyte count was 16,000; polymorphonuclears, 88 per cent. The temperature was 100; the pulse was 100.

The onset and manner of development of the symptoms suggested an acute appendicitis of approximately forty-eight hours' duration, that during the past twelve hours was giving rise to a diffuse spreading peritonitis. A laparotomy was immediately performed.

Operation.—A muscle-splitting incision revealed a large quantity of mucopurulent exudate, a marked peritonitis, and an appendix very evidently not the source of the trouble. The tip of a tensely distended gallbladder was palpable just above the upper end of the incision, which was promptly closed and an upper rectus incision made. This revealed a gallbladder 7 inches long, tensely distended, and covered by a thick, fibrinous exudate. There was neither perforation nor gangrene present. This also seemed unlikely as the cause of so widespread a peritonitis, and so the stomach was explored. There was found a punctate perforation of an old callous ulcer, just distal to the pylorus. Mucus was poring from the perforation.

The perforation was closed by infolding first with catgut and then with silk. A posterior gastrojejunostomy was performed, and following this, a cholecystectomy.

Section of the gallbladder revealed a single calcium stone, one-half inch in diameter, in the entrance to the cystic duct, which was completely blocked by inflammatory edema. The gallbladder was filled with a thick, tarry bile, and its walls showed a chronic fibrous thickening, on which was superimposed the acute process, brought on, doubtless by movement of the stone.

Postoperative Course.—The abdomen was closed without any drainage whatsoever. The postoperative temperature ranged from 99 to 101 the first two days, and went to 102.4 on the third day; from the fourth day on it remained normal. The patient left the hospital on the fourteenth day, eating and enjoying solid food. There was no wound infection.

COMMENT

In passing, I wish briefly to comment on the treatment used. In the presence of a general peritonitis, and following a cholecystectomy, the abdomen was closed without drainage.

For the past four years at Richter's Clinic at Wesley Memorial Hospital, we have drained no abdomen following cholecystectomy when exploration of the common duct was not made. Cases of empyema and gangrene are excepted. We feel that the peritoneum is able amply to take care of the slight soiling that the stump may cause. So far, our practice has fully been justified. This I consider one of the important recent advances in the technic of gallbladder surgery.

Lastly, it is of paramount importance to differentiate the peritonitis that follows a duodenal perforation and that which follows a virulent bacterial invasion from a lower portion of the intestinal tract. The contents of the duodenum are practically sterile. The widespread peritonitis that follows free perforation is due to the acidity of these contents, and is a chemical peritonitis. The ulcer once closed, excepting in those cases already exhausted from prolonged toxic absorption, the peritoneum will take care of the remainder of the exudate. Foreign material introduced for the purpose of drainage introduces infection, and by contact with the site of recent perforation often causes a fistulous opening. Drainage following duodenal perforation is undoubtedly one of the important causes of the high mortality rate.

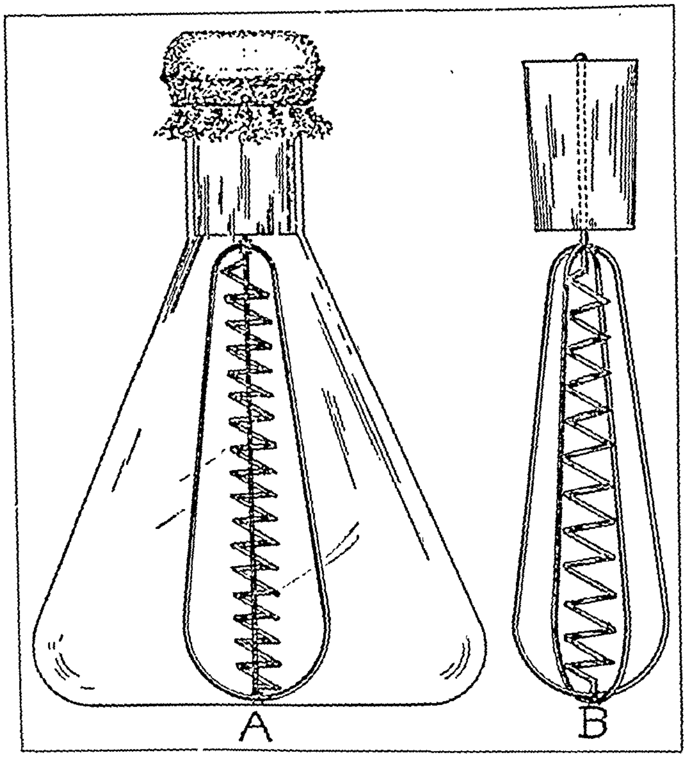
A SIMPLE METHOD FOR THE DEFIBRINATION OF BLOOD

Francois H. K. Reynolds, M.D., Washington, D. C.
Second Lieutenant, V. C., U. S. Army

The great demand, the frequent loss, and the inability to readily procure suitable beads for the defibrination of blood has prompted the designing of this simple apparatus, which has given excellent results, and which may be of interest and value to those engaged in the class of work necessitating such treatment of blood.

The apparatus consists of an ordinary Erlenmeyer flask (*A*) with a cork to fit, and a piece of looped wire, preferably copper, as copper will not rust and is readily cleaned.

The wire (*B*) may be bent into simple loops or, as set forth in the drawing, may be arranged as an elongated spiral with the two outer loops connected therewith at the top and bottom, the spiral being in the center. This tends to impart more or less rigidity to the structure and, the wire being flexible, is easily introduced into the flask. The upper process of wire extends through the cork and is fastened on the upper side.



Apparatus for defibrination of blood: *A*, Erlenmeyer flask, cork and wire complete; *B*, cork and wire.

When it is desired to procure blood aseptically, the stopper may have a glass tube introduced between the center and edge, and a plug to fit.

When the desired quantity of blood is procured, the flask is grasped by the neck, the stopper toward the palm of the hand, and defibrination accomplished by a vigorous motion not unlike ringing a bell.

After sufficient shaking, the wire is removed by withdrawing the stopper, and the fibrin will be found closely adhered to the mesh, leaving the defirinated blood within the flask.

Sickness in Relation to Family Income.—Sydenstricker, Wheeler and Goldberger of the Public Health Service made an investigation into disabling sickness among the population of seven cotton mill villages of South Carolina in relation to family income during May and June, 1916. The study covered 747 households composed of 4,161 persons. They conclude (*Public Health Reports,* Nov. 22, 1918): A higher sickness (involving inability to work) rate and a greater amount of working time lost on account of such sickness were found among members of families whose incomes were low than among members of families with a more favorable economic status. Only when a family income approximated $10 per half month per adult male unit (or about $900 a year for a family of "normal" size in 1916) did the sickness rate appear to be as low as that suggested by similar censuses in a number of localities in the United States as the normal rate. Low economic status appeared to be a more striking concomitant of high sickness rate among females than employment in mill work. A greater proportion of disabling illness, of relatively long duration, appeared among persons whose family income was below the average than among persons with a more favorable economic status. In the analysis of morbidity facts economic status should be given proper emphasis.

"THE NEEDS OF MEDICAL EDUCATION AS REVEALED BY THE WAR"

When the United States entered the great war, the Medical Corps of the Army consisted of less than 450 regular medical officers. When the armistice was signed this body had expanded to more than 32,000 officers; practically all of the increase represented volunteers from the medical profession in civilian life. The views of one of the regular medical officers regarding the great body of civilian physicians with which he came in contact on their entrance into military service appear in this issue.[1] General Munson gives his estimate of the professional qualifications of the medical men from civilian life, as seen and studied in the medical officers' training camps. He indicates that the civilian physicians entering the Army were a selected group and therefore their qualifications averaged higher than the general average of civilian physicians.

Along with General Munson's paper we are also publishing a letter[2] and a reply bearing on the same subject. In his letter Dr. Vaughan asks General Munson for an estimate of the professional qualifications of the Reserve Corps men who entered the service without passing through the medical officers' training camps. Unfortunately, the reply does not contain the information. Altogether, the number of these must have been large. For example, there were (*a*) nearly 1,000 recently graduated men, who represent the latest productions of the best medical schools, and who were sent to the British army during the summer of 1917; (*b*) the personnel of the Red Cross hospitals, who either in the early summer of 1917 or later, went directly to France; (*c*) the large number of casual medical officers who went directly overseas in 1917 or later; (*d*) the large number of reserve officers in various base hospital units in this country, some of which were later sent to France while others remained in the United States, and (*e*) the medical officers in the National Guard divisions.

In his reply, General Munson does, however, make two statements which appear to be fundamental, namely: (*a*) "The general qualifications of the great majority of the medical men entering the services were good," and (*b*) "the examinations [referred to in General Munson's paper] were conducted . . . on a wholly insignificant number of new officers."

These statements should be carefully considered by the reader in connection with General Munson's article, since they are important to any one who attempts to judge the best product of our best medical schools with their modern equipment and methods of instruction. All medical educators will agree with General Munson that perfection in medical teaching has not been reached. Nevertheless all must agree that admission to our better medical schools is now effectively safeguarded; thus preventing at the source the entrance of uneducated men. As a result of the campaign conducted by the American Medical Association, during the last fifteen years, through its Council on Medical Education, aided by the leading medical educators in this country, the requirements for admission to the medical schools of the United States have been greatly advanced, and medical education has been greatly improved in other respects.

General Munson suggests that the Army psychologic tests be applied to those seeking admission to medical schools, and states that these tests are now "employed in the hiring of artisans, clerks, etc." Even though medical officers fell below others in these alleged reliable tests of mental alertness, the training and methods of thought of physicians tend to carefully considered judgment rather than to the quickness of eye or finger that is demanded of the typesetter or artisan. It must be borne in mind that students are not now admitted to our better medical schools unless they have had a preliminary training equivalent to the training received in the first two years of a college course. They are hardly to be compared with artisans and clerks. There is *no question* as to the intelligence of these students when they enter the medical schools. There are, however, other essentials besides intelligence for those who would make a success in the practice of medicine and be an honor to the profession. The second essential is industry, and this can be tested out *only* under at least one semester of strenuous trial. Even then there is no method known by which it can be determined to what extent industry on the part of the individual will be employed in subsequent life. The third essential to an honorable position in the practice of medicine is integrity. This qualification can be determined only after close association extending through a comparatively long period.

There are men in all grades of life and in all professions who will not be industrious except when under immediate stimulation and direction. Failure to continue the industrious pursuit of scientific medicine is the cause of the greater number of lapses of those who during the past ten years have gone out from our medical schools. With this in view, the recommendation made by General Munson in his letter that physicians be encouraged to keep up with medical progress is of the greatest importance and deserves consideration from all who are concerned in medical education.

[2] Needs of Medical Education as Revealed by the War, Correspondence, this issue, p. 1095.

No apology is needed concerning the actual work and results achieved by these volunteer medical officers. They kept the medical quota more than filled without being materially stimulated by the draft. General Crowder has testified not only to the civilian physician's patriotism but also to his efficiency on the more than four thousand draft boards, and he also has disposed of the myths about men with glass eyes and cork legs being accepted for the service by medical men.

Nearly 35,000 physicians donned the khaki and blue of the Army and Navy. We venture the statement, although we have no exact figures on this point, that the volunteer medical officers rendered at least 95 per cent. of the medical service received by our soldiers in hospitals, in camps and in the field, both in this country and in France. We say these things, not boastfully, but truthfully. The medical profession did its full duty—and did it well.

GREEN FOODS AND VITAMINS

The importance of those as yet little understood food factors popularly termed vitamins has become well established in the minds of persons who discuss dietetics from a scientific standpoint. Owing to the historical development, we presume, of our knowledge of the subject, milk and its products have heretofore furnished the chief topic of discussion in relation to vitamins. Thus it is now understood that the secretion of the mammary gland includes, in addition to such excellent nutrients as proteins, fats, sugar, salts of lime and other elements, constituents that promote nutrition and growth and, if properly conserved, suffice to avert scurvy in those individuals that depend on milk as the sole or preponderating source of their nourishment. Dietary analysis, as it is now practiced through actual feeding trials by investigators of nutrition, has assumed the existence of several types of vitamins in milk: the water-soluble, the fat-soluble, and the antiscorbutic vitamins, if they may provisionally be so designated. The lack of any of these "properties" or "potencies" in a dietary during a long period is likely to lead to characteristic pathologic conditions—deficiency diseases, as they have lately been designated. Scurvy, beriberi and pellagra have already been interpreted from this etiologic standpoint.

Fortunately, the vitamins are by no means confined in their occurrence to milk and eggs. They are found widely distributed in different types of food products from animal and vegetable sources, as has been pointed out from time to time in these columns.[1] The demonstration of the existence of antineuritic vitamin in certain parts of the widely used cereals, and the loss of this essential constituent as the result of high milling, have attracted attention to the significance of methods of manipulation in the preparation of foods for human consumption.[2] It has, for example, furnished part of the problem for debate in relation to the relative value of bread made from whole wheat flour or old-fashioned corn meal, in contrast with the modern "white" bread and "highly milled" corn foods.

Although green vegetables have long been popular in the dietary in every part of the world where they are available, the real significance of their inclusion and the almost universal desire for them has been difficult to explain on the basis of the limited conceptions of food values that prevailed a generation ago. Only a few of the vegetables and fruits are especially valuable as "food fuel" or as sources of protein; hence their popularity has primarily been attributed to mineral constituents, the indigestible "roughage" that they afford, and to desired flavor. Latterly, however, a new rôle has been given to many of the vegetables as "protective" foods because of the demonstration that, like milk, they are carriers of indispensable vitamins. Carrots, cabbage, spinach, tomatoes, etc., are thus brought into a new prominence. What is evidently needed in the immediate future for the development of rational dietetics is a widespread survey of the occurrence and distribution of the vitamins in all types of food products that enter into use in the nutrition of both man and the domestic animals on which he is so largely dependent. It is precisely through such laborious studies, in which American physiologists have been conspicuous pioneers, that the danger of identifying certain butter substitutes with butter has been averted and that the necessity of thinking of foods in terms other than calories alone has been emphasized.

What is involved in this newer knowledge may be illustrated by a recent statement of Osborne and Mendel[3] in connection with their studies of vitamins in green leaves. They aver that far less dried spinach supplies sufficient water-soluble vitamin to promote normal growth than do whole wheat, soy beans, dried egg, meat, milk or potatoes. Spinach leaves are much richer in the fat-soluble vitamin than are most of the products used in our ordinary rations. So far as the limited data now available permit deductions of a general nature, it seems, according to Osborne and Mendel,[4] that the green vegetables supply an important addition to the diet of man because the staples, such as cereals, meats, potatoes, fats and sugar, probably furnish too small an amount of either of these vitamins to meet fully the requirements of an adequate dietary. Therefore care should be taken not to reduce greatly the quantity of green vegetables customarily eaten until more is learned about the actual requirements for these food factors and their relative abundance in the commonly used vegetables and green foods. Only then will it be safe to apply the results obtained in the laboratory to attempts to effect economies in the use of these relatively expensive food products. It may be quite possible for a person to omit fruits and vegetables from his diet without running the risk of obtaining enough starch, sugar and protein. But there is in fruits and vegetables an apparent safeguard to health. Their use has long been fostered by dietary tradition and personal preference; and now it is further justified by the discoveries of science.

THE SYNTHESIS OF HIPPURIC ACID IN THE BODY

In clinical discussions on the composition of the urine, one rarely finds any mention of hippuric acid. Presumably this is due to the fact that even marked variations in the content of this compound are not provocative of pathologic manifestations, as are excretory products like uric acid phosphates or oxalates. Furthermore, no abnormalities of nutrition have been associated directly with exceptional appearances of hippuric acid. Nevertheless, this substance represents the result of a highly important protective reaction on the part of the organism, namely, the conjugation of ingested benzoic acid with glycocoll supplied by the organism to detoxicate an otherwise harmful substance. Even with an ordinary mixed diet that includes fruits and vegetables, as much as 1 gm. of hippuric acid a day may be eliminated in the urine.

It is surely not without interest, therefore, to know the details of the origin of an excretory substance like this, which plays an important part in preventing harm from the damaging products to which the organism is continually exposed. As the result of the classic studies of Bunge and Schmiedeberg in Strassburg, the kidney has been regarded as the sole seat of hippuric acid synthesis. The reaction held a unique position for the reason that almost every other product appearing in the urine is brought ready-made to the kidney for elimination. The original experiments were conducted on carnivora. Subsequently it was maintained by Friedmann and Tachau[1] of Berlin that the synthesis in herbivora (rabbits) occurs not only in different organs but also in a different manner than in the carnivora, with which group man has been classed in respect to this problem.

Some time ago we pointed out that, according to observations of Kingsbury and Bell[2] in this country, in carnivora the liver also may take part in the hippuric acid synthesis. They found a relatively large amount of hippuric acid in the liver of a nephrectomized dog after injection of glycocoll and sodium benzoate. At the Michael Reese Hospital in Chicago, Lackner, Levinson and Morse[3] have investigated the problem in a different way in carnivora. They compared the urinary output of hippuric acid in dogs on diets of constant composition before and after poisoning with hydrazin, a substance that causes profound liver involvement while the kidney cells are left intact.[4] There was a reduction in the output of hippuric acid as soon as the liver became seriously involved. The conclusion seems justified, therefore, that the liver participates in the usual synthesis. This is, as the Chicago investigators remark, well in keeping with what is known of the hepatic in contrast with the renal functions. Other protective conjugations, such as those of the sulphates and the glycuronates, are undoubtedly referable to the liver, if not to other organs. The production of hippuric acid apparently forms no exception to this.

Current Comment

DOES THE HEART RESPOND TO FATIGUE?

The phenomena of fatigue in skeletal muscles have been the subject of numerous experimental investigations. They have clearly demonstrated that a decrease in irritability or responsiveness to stimuli is one of the characteristics that develop. Fatigue products, so-called, seem to be produced or liberated as a result of overexertion. If they are discharged into the circulation, they can reach structures other than those immediately concerned in the contractile responses. Even distant muscles may thus give evidence of decreased efficiency, that is, fatigue; and the sensation of weariness that arises through the fatigue of muscles shows that nerve cells too can become affected. On general principles one would expect the heart also to exhibit manifestations attributable to fatigue in the skeletal muscles. However, it is a familiar physiologic fact that the heart cannot be thrown into tetanus or fatigue, as can an ordinary muscle, by repeated stimulation. This is presumably due to the peculiar property known as the refractory period, during which stimuli reaching the organ are ineffective. Nevertheless, Mendenhall[1] has shown in the pharmacologic laboratory of the Dartmouth Medical School that the heart, like other tissues of the body, is affected by the products of fatigue. Unlike skeletal muscle, its irritability is increased rather than decreased. Moderate fatigue, carried to a point possible of attainment by voluntary efforts, causes a marked rise in the irritability of the heart muscle. Mendenhall suggests the possibility that such increase in irritability has an adaptive purpose; thus, with increased activity of the skeletal muscles, the heart muscle is influenced by the increase in fatigue products in the circulation, and more readily responds to stimulation. Finally, Mendenhall adds, the continuation of the rapid beating of the heart following exercise may in part be explained by its increase of irritability, due to the presence of fatigue products It is also conceivable that continued fatigue, as in overwork, may give rise to cardiac disturbances that are the result of increased irritability of the heart muscle.

THE RELATIVE RETURN IN LAW AND MEDICINE

Some years ago a study was made of the average income of Harvard medical graduates by classes and years of experience. A questionnaire was sent to each graduate for the ten-year period of 1900 to 1910. A large number of the questionnaires were returned, and the following table was compiled:

Year in Practice	Classes									
	1901	1902	1903	1904	1905	1906	1907	1908	1909	1910
First	$866	$787	$541	$362	$625	$502	$350	$533	$425	$1,237
Second	827	1,089	790	995	773	826	588	1,250	874	1,083
Third	1,181	1,539	1,412	1,295	995	1,262	1,353	1,025	1,370	1,578
Fourth	1,505	1,694	1,720	1,566	1,559	1,765	1,963	1,575	1,632	1,835
Fifth	2,027	1,556	1,966	1,981	1,818	2,359	2,347	1,847	2,150	
Sixth	2,341	1,837	2,333	2,277	2,347	2,997	3,202	2,360		
Seventh	2,527	2,161	2,654	2,967	3,048	3,650	3,545			
Eighth	3,003	2,491	3,155	3,043	3,337	4,332				
Ninth	3,560	2,900	3,616	3,604	4,500					
Tenth	3,524	2,963	4,135	4,535						
Eleventh	3,885	3,691	4,604							
Twelfth	4,422	4,130								
Thirteenth	4,650									
Maximum number of men	38	39	29	39	33	26	29	29	25	26

In 1912 the secretary of the Harvard law school sent letters to all of the graduates of that school from 1902 to 1911 inclusive, and as a result of that questionnaire the following table was made:

Year	No. of Replies	Average Earnings	Year	No. of Replies	Average Earnings
First	694	$ 664	Sixth	249	$3,118
Second	609	1,110	Seventh	162	3,909
Third	497	1,645	Eighth	112	4,426
Fourth	411	2,150	Ninth	62	5,321
Fifth	317	2,668	Tenth	40	6,825

These tables should, of course, be studied with the thought in mind that only about one half of those written to responded, and that those who did respond probably represented the more successful members of their respective professions. The tables are instructive since they indicate that the returns from these two most important professions cannot begin to compare in actual cash increment with almost any of the ordinary commercial or trade interests. And yet the practice of either law or medicine includes many advantages which assure that the supply will never be far below the demand.

A JURY IN DRY HUMOR

A physician in North Carolina sends us a large advertisement of "Paw Paw Tonic," from which we learn—in 24-point black face capitals—that the "tonic" contains "no alcohol." One gathers from the less prominently featured parts of the advertisement that the preparation does, however, contain port wine! This, in a way, prepares one for the newspaper item which the same correspondent sent in forty-eight hours later, detailing the conviction of a Charlotte, N. C., druggist of selling this nonalcoholic "tonic" to young men who, oddly enough, after partaking of it became drunk and disorderly. Counsel for the druggist maintained that if "Paw Paw Tonic" were taken according to directions the medicine would not produce intoxication. But by an unfortunate *faux pas,* the young men failed to follow directions. Thus far the story is commonplace. The unusual feature in the case is the judge's charge to the jury. He instructed these twelve good men and true to decide whether or not a "patent medicine," which when taken in liberal quantities will produce intoxication, is an intoxicating liquor. The jury decided that such a "patent medicine" *is* an intoxicating liquor! Should this common-sense and rather obvious finding of the jury be held by the courts over the country generally, the large business that purveyors of alcoholic "patent medicines" are expecting to develop after July 1, 1919, will fail to materialize.

CHEAP BUT EFFECTIVE ADVERTISING

"I thought that 'Sal Hepatica' was advertised to the medical profession only," writes a correspondent, "at least I have seen advertisements in medical journals and not in newspapers. But questions put to me by some of my nonprofessional friends make me wonder if it is now advertised to the public." There are two ways of advertising a "patent medicine"—the direct and the indirect. The direct method consists in openly purchasing space in newspapers or on billboards to proclaim the virtues of the panacea. This method is expensive, but has in its favor the probability of quicker returns, and the virtue of an avoidance of commercial hypocrisy. The other method is to call the "patent medicine" an "ethical proprietary," advertise it exclusively in medical journals, circularize the medical profession and send sample packages to physicians. The package should contain one full-sized bottle of the nostrum for the physician himself, and a number of small, single-dose packages for the physician to pass on to his patients. The package, of course, must be distinctive in shape and character, and the name of the preparation duly set forth on the label, with a fairly comprehensive list of pathologic conditions for which the preparation is recommended. It is desirable, also, to have the name blown in the bottle. Disclosure of the formula is entirely unnecessary. There are two advantages in this indirect method. First, cheapness; second, the "patent medicine" goes to the public with the tacit approval of the medical profession. The indirect method takes a little longer to introduce the product, but in the end is just as effective, for enough physicians can always be counted on to act as unpaid agents in its distribution. "Sal Hepatica" is a "patent medicine" advertised by the indirect method.

THE MENACE OF MALARIA

The passing of the winter reminds us that the fly menace and the mosquito pest will soon be with us again. With war time activities almost entirely relegated to the background this season, the people of the United States should take up, with greater vigor than ever before, the great task of eradicating the diseases for which the summer insects are so largely responsible. Foremost stands malaria, which is said to show an incidence of six or seven million cases in this country each year. The difficulties presented are not attributable to ignorance regarding the etiology of the disease or, indeed, to uncertainty regarding the mode of control. Malaria is seven times as prevalent in rural communities as it is in urban centers; hence the large financial outlay involved in essential antimosquito work tends to fall on groups of our population least able to bear the burden. However, it ought to be understood by all parties of our commonwealths that malaria is not only injurious to health but also a business liability. *Public Health Reports,* which has recently disseminated the plea of the United State Public Health Service for renewed vigor in an antimalarial campaign, points out that there is practically no instance known of a white community thriving where malaria seriously prevails. The time for concerted effort has arrived, the possibilities of success have been demonstrated, and the physicians of this country ought to be foremost in the demand for effective preventive measures. We are assured that the Public Health Service will be glad to assist local communities desiring to engage in antimosquito activities. If desired, an experienced sanitary engineer officer will be detailed to advise such communities as to the most practicable measures to be undertaken, and to cooperate in supervising the activities carried on. Requests for such assistance should be made through the state health officer.

---

1. Public Health Reports, **34**: 543 (March 21) 1919, contains a list of publications relating to malaria and mosquito control.

The New Athletics.—The athletics of today must be remolded and their object clearly defined. Athletics can surely have no better purpose than to develop a robust and healthy boy who, though he may not be an interscholastic champion or sought after by the larger colleges as likely to increase their fame, will nevertheless enter upon his life work with a symmetrical, fully developed body, capable of resisting disease and of enduring physical strain. For such a young man the training camp, the transport and the trench will not contain the threat of death from disease before his grapple with the enemy.—Lieut. D. F. Luby, *Naval Medical Bulletin,* October, 1918.

Association News

THE VICTORY MEETING

Committee on Arrangements Opens Office and Will Aid Hotel Reservations

The Local Committee on Arrangements for the "Victory Meeting"—the 1919 annual session to be held at Atlantic City, N. J., June 9-13—requests that all correspondence addressed to the committee or to its subcommittees should be mailed to 1801 Pacific Avenue, Atlantic City, N. J., the office of the Local Committee on Arrangements. The committee has found that certain of the hotels located on the Boardwalk are already filled for the week of the annual session. There are, however, ample and excellent hotel facilities still available for those attending the Victory Meeting. It is advisable that hotel reservations shall be made in advance of the annual session, and the Subcommittee on Hotels, Dr. David B. Allman, chairman, or the Central Local Committee on Arrangements itself, Dr. Emery Marvel, chairman, will gladly put Fellows in communication with the management of accredited hotels, at which accommodations may be reserved.

Foreign Guests at the Victory Meeting

The American Medical Association has been officially advised that the following have been appointed by their respective governments to represent the medical profession of their countries at the Victory Meeting:

Belgium—General Melis, Colonel A. Depage, Dr. P. Nolf and Prof. J. Duesberg.

Cuba—Dr. Juan Guiteras, Director of Public Health.
Dr. Emilio Martinez, Professor in the National University.
Dr. Julio Carrera, Chief Surgeon of the Main Havana Emergency Hospital.

Medical Mobilization and the War

Personnel of the Medical Corps

For the week ending April 4, the Medical Corps contained 19,318 officers, a decrease from the previous week of 337. The Medical Reserve Corps contained 1,460 officers. The total number of medical officers discharged since the beginning of the war is 14,220.

New Chief of Section on Head Surgery

Under date of April 1 Lieut.-Col. Nelson Miles Black, M. C., U. S. Army, was designated as officer in charge of the section of head surgery, Surgeon-General's Office, vice Col. Walter R. Parker.

New Senior Consultant in Neuropsychiatry for A. E. F.

Lieut.-Col. E. G. Zabriskie of New York City has been designated senior consultant in neuropsychiatry for the American Expeditionary Forces, succeeding Col. Thomas W. Salmon, who has returned to the United States for duty in the Surgeon-General's Office. Lieutenant-Colonel Zabriskie went to France as divisional neuropsychiatrist of the fourth division. Subsequently he was consultant in neuropsychiatry to the third and fifth corps and the first army. After the armistice he served as consulting neuropsychiatrist to the Savenay hospital center.

British Greet American Medical Officers

One hundred American medical officers were recently accorded, it is reported, the first official reception ever given by British medical organizations to American physicians. These physicians arrived in London to take up postgraduate work in England. Speakers at the reception included Sir Humphrey D. Rolleston, president of the Royal Society of Medicine, who acted as host; Sir Rickman J. Godlee, president of the Royal College of Surgeons; Sir Norman Moore, president of the Royal College of Physicians, and Sir William Arbuthnot Lane, consulting surgeon to Guy's hospital.

Medical Veterans of World War to Hold Organization Meeting

The acting officers of the Medical Veterans of the World War announce that a meeting for the purpose of effecting a permanent organization will be held Friday evening, June 13, at an hour to be announced in the *Daily Bulletin* issued during the annual session of the American Medical Association. As previously announced Col. F. F. Russell, Army Medical School, Washington, D. C., is secretary of the temporary organization. Those interested should write to him for forms for making application for membership. These applications should be accompanied by a fee of $1 to assist in defraying expenses incident to the organization and in arranging for the Atlantic City meeting. Copies of the constitution and by-laws and application blanks may also be obtained from the headquarters of the American Medical Association. Send stamped addressed envelope.

Army Medical Exhibit

On April 4 there was opened at the Army Medical Museum in Washington an exhibition of the medical activities of the war. The exhibit contains a plan of the proposed medical center at the Walter Reed Hospital, showing the architects' plan and sketches of the medical center, photographs of the present quarters and the military hospital at Fort McDowell, Calif. Another section is devoted to the work of the roentgen-ray department of the Army, showing the different units and apparatus used during the war. A third exhibition concerns infectious diseases and laboratory detail of methods of combating infectious diseases, with a graphic representation of the results. The section on surgery shows, by photographs, methods of removal of wounded, transportation, types of hospitals, wax models showing the effects of mustard gas burns and other injuries and the Carrel-Dakin method of treatment. The section on orthopedic surgery is devoted to orthopedic devices, litters, splints, etc. The division on physical reconstruction illustrates the work of this department in caring for the wounded soldier and developing him so that he may be fit for useful industrial life. The section on neuropsychiatry exhibits by means of charts the work of that department; also by photographs of hospitals and cases displaying clearly some of the difficulties which this department had to overcome. Another section concerns the Army psychologic tests showing the successive steps in testing the mental capacity of officers and soldiers. Section 9 shows by legends and charts the results of physical examinations. Another exhibition is devoted to delousing, showing models of various delousing devices, and especially buildings equipped for this purpose. The food and nutrition division shows the results of the nutritional surveys, and by numerous photographs shows food and mess conditions in the various camps. Other sections display sanitation in the camps and sanitary appliances. The exhibit of the vital statistics division shows the use of the perforated statistical cards by which it is possible to rapidly determine the prevalence of various conditions. The final section, called the war museum of the Army Medical Museum, comprises three sections of materials received from France monthly since the beginning of the war, including weapons, rifles, machine guns, helmets, gas masks, pathologic specimens and wax models.

Weekly Bulletin, A. E. F.

(March 10, 1919)

BLOCKADE EFFECTS IN GERMANY

This number of the *Bulletin* contains extracts from a report of the chief sanitary officer of civilian affairs, advance general headquarters, A. E. F., dealing particularly with undernourishment in Germany. The report points out that the death rate in Hanover has gradually risen from 9.19 per thousand per year in 1913 to 16.40 in 1918; in Berlin, from 13.48 in 1913 to 20.05 in 1918. These figures may be compared with the average death rate of New York state during 1917 of 15.5. It is stated that there were 56,861 deaths from tuberculosis in Prussia in 1913 and 86,217 in 1917, and that the death rate from this disease for Germany has gradually risen from 136.5 in 1913 to 205.7 in 1917.

In other portions of Prussia the death rate has also gradually risen. In the region of Trier it has risen from 102.3 in 1908 to 191.3 in 1918, and in Coblenz from 150 in 1915 to 352 in 1918.

Observers of the population have been led to believe that the war diet has undoubtedly been of advantage to stout, overfed people so that such diseases as diabetes and eclampsia have greatly diminished. No special change has been noted in heart and kidney diseases. Observations of infants lead Dr. V. von Franque to state that the problems, complications and accidents of labor have not increased, but that the average weight of the new-born has decreased from 7 pounds and 4 ounces to about 6 pounds. It is stated, further, that the ability of mothers to nurse infants is decreasing. The minister of the interior states that deaths of children from 1 to 5 years of age increased in Cologne. The report states also that as far as can be ascertained, the entire nation has been rationed since the winter of 1915 and since that time this ration has been under the daily needs of the people and has steadily grown worse. The majority of the people are believed to be far below their normal health weight.

Just how serious the permanent damage will be to each individual or to what proportion of the entire population is impossible to estimate. The shortage of medical and surgical supplies and certain needed drugs has been an unfavorable factor and has led to an increase in the mortality of sick persons.

CONCLUSIONS

Among the conclusions it is stated:

Child Birth. Accidents of labor have not increased. Eclampsia is diminished.

Infants. Children at birth are possibly a little below normal average weight. German authorities state that infant mortality is increasing but there is no evidence to prove it.

Children, 1 to 6 years of age.—The majority of children do fairly well. There is a definite increase in the number of deaths in various localities.

Children of school age—6 to 14 years. These children do badly. There is definite evidence to show that a very large proportion are underfed. They are anemic, poorly nourished and undersized. Children who should be gaining weight each month are losing weight or are remaining stationary. Skin diseases are prevalent. Many children are infested with lice and scabies. Tuberculosis, especially scrofula, is markedly increased.

Adults. Stout persons in good financial condition have lost weight but have been generally benefited. The well-to-do have remained in good condition. The majority of the people are thin, undernourished; their capacity for work and their natural resistance to disease are diminished. The sick in hospitals do badly; resistance is diminished after operations, convalescence retarded. The proportion of cases dying in hospital has markedly increased.

TYPHOID SUSPECTS

With a view to excluding or establishing the diagnosis of typhoid or paratyphoid fever, the chief surgeon has indicated that blood cultures will be taken in the case of all typhoid suspects on admission. If negative, two more blood cultures will be taken at the end of forty-eight and ninety-six hours, respectively, and additional blood cultures will be taken every seven days throughout the course of the illness and on the onset of relapse. In cases of fever of unknown origin three successive blood cultures are to be taken at forty-eight hour intervals, following admission to the hospital. Fecal cultures for typhoid-like organisms are to be made in all cases of typhoid suspects or in fevers of unknown origin of forty-eight hours' duration. Patients in whose stools typhoid-like organisms have been discovered are not to be discharged from the hospital on a duty status until three successive negative fecal and urine cultures have been obtained, the cultures to be taken at weekly intervals. The Widal test is also to be determined at seven-day intervals in each suspected and proved case.

WEEKLY REVIEW

During the past week there have been increases in reported cases of chickenpox (5), diphtheria (13), measles (19), scarlet fever (13) and typhoid fever (30). The reports of typhoid fever totaling 51 cases, include 31 suspects and 3 carriers. Only one case of paratyphoid was reported. Cases of meningococcus meningitis have fallen from 40 to 28 during the past week. The main "foci" of diphtheria are in the army of occupation and in the army troops in and about St. Nazaire. The annual venereal disease rate per thousand strength has risen to 36.69 from 34.20 for the previous week. The cause of the rise in the venereal rate appears to be the greatly increased number of exposures in the leave areas and the high percentage of failure to take prophylaxis after exposure. Medical officers are advised to study the conditions in their own organizations, paying particular attention to the condition of the prophylactic stations and the ratio of exposures to new cases and failure to use prophylaxis.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

ARKANSAS

Personal.—Dr. Wheeler S. McCall, Blytheville, has recently returned after service in France.

Public Health Service Discontinued.—The city council of Little Rock has received notices from the United States Public Health Service that the government will close the station at Little Rock about June 30, on account of there being no funds available for the continuance of the work. The Red Cross activities will also be discontinued on the same date because of the lack of funds. This work has been carried on under the following heads: malaria control, communicable disease control, venereal disease control, school inspection, public health nursing, control over production and sale of milk and milk products, control over preparation and sale of foods and drinks, control over slaughtering and sale of meats, control over barber shops and manicure parlors, sanitary inspection and sanitation, rural sanitation, laboratory, publicity, education, and general health work not included under the foregoing heads.

CALIFORNIA

Physicians Lose Licenses.—The state board of medical examiners, March 21, is reported to have revoked the medical licenses held by Drs. James Ottis, Burnette and George H. Richardson, Los Angeles, charged with having performed illegal operations.

Lane Lecture.—The sixth popular medical lecture under the auspices of the medical faculty of Leland Stanford Junior University, San Francisco, was delivered, March 31, at Lane Hall, by Dr. William C. Hassler, San Francisco, who spoke on "The Control of Epidemics."

Correction.—In the California news which appeared in The Journal, March 22, it was stated that Dr. Slocomb R. Edwards had been appointed chief of the ear, nose and throat department of Leland Stanford Junior University. Dr. Edwards notifies The Journal that this is an error, as his appointment is as assistant to Dr. Edward C. Sewell, San Francisco, chief of the Lane Ear, Nose and Throat Clinic of Stanford University.

Personal.—Dr. Timothy Lyman, Sacramento, has resigned as superintendent of the Sacramento County Hospital, and located in Eau Claire, Wis.——Dr. Thomas B. W. Leland, coroner of San Francisco County, formerly Surgeon, Lieut.-Com., U. S. Navy, and senior medical officer of the Second Division of the Pacific Fleet, has been discharged from the service.——Dr. William J. Galbraith, Burbank, has been appointed district surgeon for the Southern Pacific System.——Dr. George H. Sciaroni, Fresno, has been placed in charge of the social disease clinic to be established at the Fresno City Hospital.

GEORGIA

Healthology.—The bulletin of Georgia State Board of Health has been made a monthly instead of a quarterly publication, and Roy C. Werner, B.S., has been appointed its editor.

Personal.—Dr. Charles R. Bullock, Kirkwood, Capt., M. C., U. S. Army, on duty with the Seventh Division overseas, has been promoted to Major, M. C.——Edwin S. Byrd, Capt., M. C., U. S. Army, Atlanta, who went overseas in September, 1918, has been honorably discharged from the service and has taken up practice in Moultrie.

IDAHO

New Tuberculosis Hospitals.—March 14, Governor Davis signed House Bill No. 117, passed by the legislature, which authorizes a tax levy to provide funds for the establishment of two tuberculosis hospitals in the state.

Personal.—Frederick T. Harris, Capt., M. C., U. S. Army, Lewiston, who has been in France for about eight months, has been promoted to Major, M. C., U. S. Army.——Johan Christian Wilk, Capt., M. C., U. S. Army, Moscow, has been promoted to Major, M. C.——Joseph Aspray, Capt., M. C., U. S. Army, Moscow, who has been serving overseas, has returned, received an honorable discharge, and resumed practice.——Dr. Fred A. Pittenger, Boise, has been appointed physician to the soldiers' home.

ILLINOIS

Full-Time County Superintendent.—The draft of a bill was completed, April 2, under the direction of Dr. C. St. Clair Drake, Springfield, director of health, which provides a full-time health superintendent for each county in Illinois at a salary of not less than $1,800 a year.

Medical Society Reorganized.—Physicians of Williamson County met in Marion, March 13, to reorganize the Williamson County Medical Society, and elected the following officers: president, Dr. Dallas S. Boles, Herrin; vice president, Dr. Edward E. Woodside, Marion, and secretary-treasurer, Dr. Joseph G. Parmley, Marion.

Orthopedic Clinics for Deformed.—Clinics are now being held in sixteen of the principal cities of Illinois for the free relief of children from various deformities and physical defects. The work is being done under the direction of the child hygiene department of the state, of which Dr. Clarence W. East, Springfield, is in charge.

Chiropractors Fined.—Miss Clara Kaep, a chiropractor of Rockford, was arrested by an inspector of the Department of Registration and Education of the State of Illinois for practicing without a license, and was fined $25 and costs.——J. C. Shrock, a chiropractor of Verdun, was arrested by the department of registration and education, and fined $50 for practicing medicine without a license.

Personal.—Dr. James W. MacDonald has been elected first president of the Union League Club, Aurora.——Dr. C. St. Clair Drake, Springfield, director of the state department of public health, delivered an address before the Illinois Academy of Science at Jacksonville on "The Effect of the War on Science, and the Responsibility and Opportunities of Science under the New Order of Things—Medicine and Public Health."——Drs. William Barnes, Clare A. Garber, Charles E. Hildreth and Robert L. Morris have been appointed members of the board of directors of the department of social hygiene of Decatur. This department will have charge of the free venereal clinic which is to be opened at the Decatur and Macon County Hospital.

Chicago

Loyola Faculty Changes.—Dr. Bertha Van Hoosen has been appointed professor and acting head of the department of obstetrics; Dr. Louis D. Moorhead has been appointed secretary of the faculty; Dr. George W. Wilson, of the Rockefeller Institute, professor and head of the department of pathology, bacteriology and preventive medicine; Ruben Myron Strong, Ph.D., formerly professor and head of the department of anatomy at Vanderbilt University, Nashville, Tenn., has accepted a similar position, and Dr. Thesle T. Job, of the University of Iowa, Iowa City, and Dr. Alden B. Dawson, formerly of Harvard, have been appointed assistant professors of anatomy, in Loyola University School of Medicine.

Personal.—Dr. Joseph L. Miller, Lieut.-Col., M. C., U. S. Army, has returned from military service and resumed practice.——Albert B. Yudelson, assigned to duty at the Hôpital La Fouche for a year, has returned and resumed practice.——Dr. Thomas A. Woodruff announces his removal to New London, Conn.——Harry E. Mock, Lieut.-Col., M. C., U. S. Army, has been selected as one of the delegates for the United States at the Interallied Reconstruction Congress to meet in Rome, next month.——Henry F. Lewis, Major, M. C., U. S. Army, has returned to Chicago and resumed practice.——Dr. Ethan A. Gray has been appointed medical member of the District Case Board of the Federal Board for International Education, Eighth District, which comprises Illinois, Wisconsin and Michigan.——J. W. Vanderslice, Capt., M. C., U. S. Army, has returned to Chicago and resumed practice.

Base Hospital Returns.—Under command of Major Payson L. Nusbaum, 146 men of Base Hospital No. 12, the Northwestern University Base Hospital Unit, reached New York on the *Leviathan*, April 2. The unit is to be demobilized at Camp Grant after a short preliminary stay at Camp Mills. Among the officers in the home-coming group are Majors Herbert B. Woodard, Martin R. Chase, Toulon, Walter H. Nadler, Summer L. Koch and Charles W. Freeman; Capts. Joseph J. Lebowitz, John T. B. Bird, Walter L. Stranberg, Hillier L. Baker, Charles E. Lindsay, Willis S. Gibson, Robert W. Eaton, Cyril J. Glaspel, John Henkin, Erying O. Ravn, Lyman A. Copps, Alexander H. Barnett, Edwin Robert Talbot, Willis C. Strange, Stanley W. Clark and Charles A. Short, and Lieuts. Clarence W. Robertson, Walter S. Sieworth, William Henry Johnson and Elmer C. Roberts, M. C., U. S. Army.

INDIANA

Personal.—Dr. George R. Andrews, Muncie, who has been seriously ill, is reported to be improving.——Dr. Arthur F. Fagaly, Lawrenceburg, has been reappointed a member of the Dearborn County Board of Health.

District Society Meeting.—The Thirteenth District Medical Society at its meeting held in Goshen, March 20, reelected Dr. John C. Fleming, Elkhart, president; Dr. Samuel C. Loring, Plymouth, vice president, and Dr. Charles C. Dubois, Warsaw, secretary.

Physicians Convicted.—Dr. George Koons, Indianapolis, is reported to have been found guilty of violation of the Harrison Narcotic Law and to have been fined $25 and costs and given a suspended sentence of ninety days in jail.——Robert Clark, Batesville, who pleaded guilty in Bartholomew Circuit Court to the charges of practicing medicine without a license, is said to have been fined $200 and costs and sentenced to imprisonment at the state farm for 200 days.

IOWA

Children's Hospital Opened.—The new Children's Hospital at the University of Iowa, Iowa City, was informally dedicated, March 23. The building has cost $150,000 and is constructed in pavilion style. The administrative section is two stories in height, the upper rooms being used as quarters for interns, and is connected by corridors with the orthopedic and pediatric wards. The institution will accomodate about 100 patients.

Personal.—Wilbur S. Conkling, Major, M. C., U. S. Army, Des Moines, commanding officer of the 117th Sanitary Train, 42d Division, and stationed at Neuenahr, Germany, has been promoted to lieutenant-colonel, M. C.——Lee E. Shafer, Lieut., M. C., U. S. Army, Walcott, has returned after fifteen months' service with the American Expeditionary Forces in France.——Charles L. Patterson, Capt., M. C., U. S. Army, Westside, has returned after eleven months in France.——Dr. William J. Egloff, Mason City, who has been seriously ill, has recovered.——Dr. Peter E. James, Elk Horn, who has been in ill health for a long time, has left for California.——Dr. Floyd B. Langdon, Des Moines, has resigned as physician of Polk County.

LOUISIANA

Personal.—John B. Elliott, Jr., and J. Birney Guthrie, Capts., M. C., U. S. Army, both of New Orleans, have returned from France.

Hospital Unit Homeward Bound.—The Loyola Hospital Unit, made up of approximately 300 New Orleans men and women, which sailed for France, July 10, 1918, sailed from Genoa for the United States, March 29. The organization is commanded by Joseph A. Danna, Lieut.-Col., M. C., U. S. Army, and William W. Leake, Major, M. C., U. S. Army, is head of the surgical division of the unit.

Medical Staff for Venereal Clinic.—Dr. Oscar Dowling, president of the state board of health, announces the following appointments on the medical staff of the Venereal Hospital and Clinic at Alexandria, which is maintained by the parish of Rapides, and the city of Alexandria, and the United States Public Health Service, under the charge of Dr. Charles

M. Abbott, Ponchatoula: Dr. Mayer A. Newhauser, New Orleans, chief of the clinic; Mr. J. H. O'Neill, sanitary engineer and assistant director for the state board of health, and J. D. Lobanhoffer, chief of the laboratory.

MARYLAND

Personal.—Dr. Martin F. Sloan, superintendent of Eudowood Sanitarium, Towson, has left for his home in San Antonio, Texas.

Lectures on Motherhood.—The first of a series of public lectures on the problems of "Motherhood" was given by Dr. J. Whitridge Williams, Baltimore, of the Johns Hopkins University, in the lecture room of the School of Hygiene and Public Health, April 3. In the lectures, which are for the education, advancement and protection of motherhood, Dr. Williams will deal with marriages, the health of mothers, unwholesome causes affecting the birth rate of the present age, care and health of babies, and educational equipment necessary for handling the problem of motherhood. The lectures, which are free to women of Maryland, are the result of the Child Welfare Drive conducted by the Women's Section of the Maryland Council of Defense, in cooperation with the Children's Bureau of the government.

Appropriation to Take Care of Insane Soldiers.—The problem of taking care of the state's insane soldiers was solved recently by the action of the executive committee of the Maryland Council of Defense in appropriating $25,000 for that purpose. Since all the hospitals for the insane in the state are crowded, the only way accommodations can be provided for soldiers is by equipping the building at the Spring Grove State Hospital, known as the Arthur D. Foster Psychopathic Building. The need of these facilities is urgent; and now that the amount necessary to complete the building has been appropriated, work will be begun immediately and the building will be ready for occupancy by July 1. The government has arranged to pay the maintenance for the patients, provided the state will provide housing accommodations.

MINNESOTA

Personal.—Dr. Ignatius J. Murphy, St. Paul, has resigned as assistant secretary of Minnesota Public Health Association to take up postgraduate work in Boston.——Dr. Bernard J. Gallagher, Lieut., M. C., U. S. Army, Waseca, who was attached to the British army, captured at the Battle of the Somme and imprisoned at Villingen, Germany, delivered an address at the noonday meeting of the Hennepin County Medical Society, April 2.——John C. Staley, Major, M. C., U. S. Army, St. Paul, on duty with Base Hospital No. 25 at Nantes, France, has been promoted to Lieut.-Col., M. C.——Leonard G. Rowntree, Lieut.-Col., M. C., U. S. Army, chief of the Department of Medicine of the University of Minnesota Medical School, has returned from abroad.

MONTANA

Personal.—Ellis A. Johnston, Capt., M. C., U. S. Army, Helena, has returned after a year of service with the American Expeditionary Forces in France.

County Health Officer.—The commissioners of Gallatin County met at Bozeman, March 31, and agreed to cooperate with the local authorities and establish a health organization under the charge of a whole-time health officer. It is understood that Bozeman will pay one third of the expense of the department.

Health Talks to Boys.—Arrangements have been completed with the state board of health in cooperation with the United States Public Health Service working with the Young Men's Christian Association and local speakers to give lectures to boys of 14 years and over in the public schools of the state, on the evils of venereal disease and the importance of keeping fit.

NEW YORK

Clean Up Week.—In a letter to mayors, village presidents and boards of health, Dr. Hermann M. Biggs, state commissioner of health, designates the week beginning April 14 as the annual clean up week. The local authorities are requested to take steps to notify all citizens of the date and the purpose of Clean Up Week, and are also urged to make arrangements for the proper disposal of all refuse collected during the week.

Uniform Budget Systems.—A uniform budget system has been prepared by the state department of health, the state comptroller, the New York State Conference of Mayors and certain other city officials for the use of second and third class cities. This is now being sent to health officers. In addition to the budget there is a uniform departmental accounting system which has been planned for health officers. It is believed that the uniform budget system will not only be useful to the cities for which it is intended but will also be of value to the health officers of consolidated districts as well as of all the larger villages of the state. It is being sent to all such officials.

Amendments to Sanitary Code.—The following amendments to the Sanitary Code, adopted by the Public Health Council of the New York State Department of Health went into effect, March 1:

In regulation 36 of Chapter 11 the following paragraph was inserted: "Typhoid or paratyphoid fever, if the patient's occupation involves the handling of milk, dairy products, or other food, until all signs of the disease, or secondary or complicating infections incited by the agents of these diseases, have disappeared, and until two successive specimens of the intestinal discharges of the patient have been taken at an interval of not less than seven days and have been examined in a laboratory approved by the state commissioner of health and found to be free from typhoid or paratyphoid bacilli."

Regulation 13 relating to the delivery of milk has been amended to read: "Such milk must be delivered within thirty-six hours after pasteurization between April first and November first and within forty-eight hours after pasteurization, between November first and April first, *and such cream within forty-eight hours* after pasteurization, unless a shorter time is prescribed by the local health authorities."

The resolution regarding the qualifications of Public Health Nurses requiring that these nurses be 21 years of age and registered at the time of their appointment has been repealed.

The following regulation on shaving or lather brushes has been added: "No shaving or lather brush shall be manufactured, offered for sale, or used unless the hair or bristles thereof shall have been so treated for the purpose of destroying anthrax germs as to conform with the regulations of the state commissioner of health."

New York City

Personal.—Dr. Royal S. Copeland, commissioner of health, has issued a statement announcing his intention to resign "within a reasonable length of time," that is, after the mayor has had an opportunity to choose a successor for the office.——Dr. Simon Flexner, director of laboratories of the Rockefeller Institute for Medical Research, has been elected an associate member of the Paris Biological Society.

Community Health Committee.—At a meeting of the Community Councils for National Defense held, April 5, under the chairmanship of Dr. Lee K. Frankel, a health community council was appointed to bring health questions clearly before the people. The committee includes Drs. S. Josephine Baker, John W. Brannan, Henry Dwight Chapin, Sigismund S. Goldwater, Louis I. Harris, L. Emmett Holt, E. H. Lewinski-Corwin, Ralph Waldo Lobenstine, Frederick Peterson, Thomas A. Storey, Simon Tannenbaum, Herbert B. Wilcox, and Thomas D. Wood and a number of men and women interested in public health work.

Revision of the Workmen's Compensation Act.—At a special meeting of the executive committee of the Physician's Protective Association at New York, April 2, resolutions were adopted setting forth the fact that the governor has demanded immediate revision of the workmen's compensation act, to protect direct settlement between indigent employees and insurance carriers, and calling the attention of the governor and legislature to a similar condition relating to the payment of physicians' fees by the insurance companies, owing to the impotency of the provisions of the workmen's compensation law either to provide a proper fee for medical service or to compel the payment of the fee awarded by the commission against the insurance companies, and urging that the governor include in his proposed revision of the workmen's compensation law a remedy for this form of injustice to the medical profession.

Report of Public Health Committee.—The report of the principal activities of the Public Health Committee of the New York Academy of Medicine for the year 1918 has been submitted to the academy by the secretary of the committee, Dr. James Alexander Miller. Among the subjects which have engaged the attention of the committee and on which opinions have been expressed and advice offered are included: malnutrition among schoolchildren; drug addiction; industrial diseases; reorganization of the city department of health; chief medical examiner; harbor pollution; nursing problem; dispensaries; influenza, and city budget. A number of miscellaneous subjects were also submitted to the committee for special inquiry and study, among which were ventilation in institutions for children, the mortality of women from puerperal causes, the home hospital experiment for tuberculous families, community councils, the control of venereal diseases, the medical problems of the Home Service Section of the American Red Cross, physical training of schoolchildren, and the situation in reference to garbage removal.

Bill Providing Care for Tuberculous.—A bill introduced into the legislature by Senator Julius Miller, and carrying an initial appropriation of $1,000,000, provides for state and county aid in the treatment of poor persons suffering from tuberculosis. According to the terms of this bill the state should pay one third, the county one third, and the patient himself, or through funds supplied from private sources, one third of the cost of care and treatment. Local health authorities are required to make a survey of their districts and report to the state health department a list of private institutions, boarding houses or dwellings in their districts suitable to receive and care for tuberculous persons. The state health department, after investigation, is to certify a list of such places in different parts of the state and to maintain a system of inspection after these have begun to operate under health department license. The state and county aid would continue as long as the local authorities deem treatment necessary, but in no event more than a year. The plan provides only for patients who are not bedridden or in need of bedside care or nursing. The state department of health is authorized to fix uniform rates for board and lodging in licensed places. A person must be a citizen of the United States and must have resided in New York State for one year to come in under the benefits of this plan.

NEBRASKA

Sectarian Bill Postponed.—The state senate recently postponed indefinitely Senate Bill No. 190, which provided for the establishment of a department of eclectic and a department of homeopathic medicine in the University of Nebraska College of Medicine, Omaha. This bill was fostered by the State Eclectic Medical Society, and this legislature is the third to defeat a measure of like character.

Personal.—Roy Johnson, Lieut., M. C., U. S. Army, Holdrege, returned, March 26, from overseas service.——R. Allyn Moser, Lieut., M. C., U. S. Army, Omaha, who was on duty with the British Army in France and later with the American Expeditionary Forces, has returned from abroad.——Dr. Samuel J. Stewart, Hastings, has been appointed a member of the advisory board to the state board of health, succeeding Dr. William T. Johnson, Pawnee City, deceased.——Dr. Frederick A. Sedlacek, Omaha, is a member of the American Red Cross Commission to Serbia which sailed from San Francisco, March 25.

NORTH CAROLINA

State Society Meeting.—The annual meeting of the Medical Society of the State of North Carolina will be held, April 15-17, at Pinehurst. April 14, the North Carolina Health Association will convene.

Personal.—Joseph H. Way, Major, M. C., U. S. Army, Waynesboro, and president of the North Carolina State Board of Health, who has been for nearly two years in the United States service, has been honorably discharged and has resumed practice.——Charles O'H. Laughinghouse, Lieut.-Col., M. C., U. S. Army, Greenville, a member of the North Carolina State Board of Health, recently returned from overseas, has been discharged and resumed practice.——Dr. C. Curtis Hudson, city health officer of Charlotte, was presented with a silver loving cup by the Rotary Club of that city at a dinner a short time ago.

OHIO

Hospital Opened.—The Greenfield Hospital, Greenfield, was formally opened, March 26. The president of the institution is Dr. Robert J. Jones.

Nonmedical Bill Signed.—The Talley bill which regulates nonmedical practitioners, and which has passed the house and senate, was signed by Governor Cox, March 19.

Personal.—Dr. Aldo V. Sibert has been named physician of the Lima health clinic.——Campbell F. G. Norlin, Cleveland, has been appointed medical superintendent of the Cleveland City Hospital, succeeding Dr. Thomas A. Ellison.——Roland E. Skeel, Major, M.C., U. S. Army, Cleveland, who has just returned from France, delivered an address in Lorain, April 1, on "American Surgeons in the War—A Lesson in Preparedness."——Charles H. MacFarland, Major, M. C., U. S. Army, Cleveland, has been promoted to Lieut.-Col., M. C., U. S. Army, and is now in command of Evacuation Hospital No. 23, Coblenz, Germany.——Dr. Grant S. Van Horn, Batavia, has been appointed physician of Clermont County.——James E. Miller, Capt., M. C., U. S. Army, Steubenville, has returned after nearly a year of service in France.——Benjamin C. Barnard, Major, M. C., U. S. Army, Alliance, in command of Field Hospital 309, American Expeditionary Forces, France, has been cited "For conscientious devotion to duty and untiring energy in caring for sick and wounded under exceptional adverse circumstances, from Nov. 2 to Nov. 20, 1918, following an attack on Nov. 1, 1918."——Dr. Harry L. Rockwood, acting health officer of Cleveland, has resigned and will enter private practice.

Cincinnati

Personal.—J. Louis Ransohoff, Major, M. C., U. S. Army, has returned from abroad.——Charles E. Kiely, Lieut., M. C., U. S. Army, formerly neurologist of Cincinnati Base Hospital No. 25, who has been on duty for nine months at Allery, France, has returned.

PENNSYLVANIA

Society Urges Improvements.—The Allegheny County Medical Society, after an inspection of the Tuberculosis Sanatorium and the Muncipal Hospital, sent a communication to the County Council, May 24, asking that an item for $500,000 be inserted on the proposed bond issue to be voted on by the people, for improvements to these institutions.

Personal.—Dr. Howard L. Hull, Camp Hill, has been appointed chief medical inspector of the state department of health of Pennsylvania.——Dr. Fred H. Bloomhardt, Captain, M. C., U. S. Army, Altoona, on duty with the Three Hundred and Twenty-First Infantry, has been promoted to lieutenant-colonel, and is taking a postgraduate course in medicine at the Sorbonne, Paris.——Dr. Marianna Taylor, Wayne, has been placed in charge of the medical department of the reconstruction work carried on by the Society of Friends in France.

Philadelphia

Mary Scott Newbold Lectures.—The second of the Mary Scott Newbold Lecture Series was given at the College of Physicians of Philadelphia, April 4, by Col. Thomas W. Salmon M. C., U. S. Army, on "War Neuroses and Their Lesson."

Personal.—Dr. Marie K. Formad of the Women's Hospital has returned from France, where she has been the past year doing relief work among the refugee civilians.——Hubley R. Owen, Captain, M. C., U. S. Army, former chief surgeon of the fire and police departments of Philadelphia, arrived in New York, April 5, and will go to Camp Custer, Mich., to be mustered out.——Dr. James R. Bean has been appointed health commissioner and director of the State Cooperative Laboratory, Oshkosh, Wis.

Workmen's Compensation Law Meeting.—At a stated meeting of the Philadelphia County Medical Society held in Thompson Hall, College of Physicians, April 9, amendments to the workmen's compensation law were the subjects of discussion. The speakers were Harry A. Mackey, chairman of the Workmen's Compensation Board of Pennsylvania; Francis H. Bohlen, general council of the workmen's compensation bureau of Pennsylvania; Mr. Charles A. Gill, superintendent of the Germantown Hospital, and Dr. Fred L. Van Sickle, Olyphant, president of the Medical Society of the State of Pennsylvania.

VIRGINIA

Personal.—Stuart McGuire, Lieut.-Col., M. C., U. S. Army, Richmond, director of Base Hospital No. 45, American Expeditionary Forces in France, has returned from overseas, has been elected president of the Medical College of Virginia, and has gone to Florida to take a few weeks of rest.——Dr. William F. Mercer has been elected associate professor of laryngology in the Medical College of Virginia, succeeding Dr. Samuel C. Bowen, deceased.——Dr. Isaac C. Harrison, Danville, qualified, March 14, as a member of the state board of medical examiners, succeeding Dr. Richard S. Martin, Stuart, deceased.——Dr. John L. Nall, Danville, is reported to be ill with smallpox.——James H. Smith, Joseph F. Geisinger and Robert H. Wright, Capts., and Beverley F. Eckels, Lieut., M. C., U. S. Army, all of Richmond, members of the McGuire Base Hospital Unit, have returned from France.

CANADA

Hospital News.—For an emergency hospital for Vancouver, B. C., the British Columbia government will give a donation of $3,000, the city giving a like amount.——The Invalided Soldiers' Commission will establish a new military hospital at Saskatoon, Sask.

Personal. — Dr. Peter V. Faucher, Quebec, has been appointed professor of materia medica of Laval University, Montreal.——Dr. L. G. McCabe, Windsor, fractured his leg recently while playing baseball.——Lieut.-Col. Clifford H. Reason, London, Ont, who is commanding No. 3 Stationary Hospital, Doullans, France, will shortly return to his home.——Dr. Gideo Silverthorn, Toronto, who recently returned from Florida, is ill with double pneumonia.——Dr. Lewis L. Reford is expected home in Montreal next week from overseas.——Sir Thomas G. Roddick has returned to Montreal after spending the winter in Florida.

LATIN AMERICA

Plague in Argentina.—A report from Buenos Aires states that the government has sent a commission into the province of Jujuy for the purpose of fighting an epidemic of bubonic plague which is reported to be serious.——The Santiago dispensary reports 605 cases of typhus fever with thirteen deaths.

Death of Penna.—The sudden death of Dr. José Penna, professor of epidemic diseases at the University of Buenos Aires, known the world around as an authority on epidemiology, and a pioneer in public health matters, is reported. He had long been on the editorial staff of the *Semana Medica,* and was a member of local, national and international scientific associations.

Public Hygiene in Paraguay.—The *Revista Medica del Uruguay* reports that the Departamento Nacional de Higiene and the Asistencia Publica in Paraguay have been consolidated. A number of new decrees have been promulgated, among them some relating to the drinking water, to child labor, to drainage of swamps, hygiene of markets, veterinary inspection, disinfection of vehicles, municipal charities, and the sending of commissions into the interior of the country for purposes of prophylaxis and treatment of diseases.

GENERAL

Debarkation Hospital Abandoned.—It was announced, March 25, that Debarkation Hospital No. 52, Richmond College, Va., had been discontinued, its use being no longer required.

Tri-State Physicians to Meet.—The semiannual meeting of the Northern Tri-State Medical Association will be held at Elkhart, Ind., April 30, under the presidency of Dr. George V. Brown, Detroit.

Bequests and Donations.—The following bequests and donations have recently been announced:

For the continuance and extension of the social service department of Sloan Maternity Home as a memorial to Dr. Edward B. Cragin, voluntary subscription for $50,000.

Harvard University, the income on the residuary estate of Horace Fletcher, to be used to "foster knowledge of healthful nutrition."

St. Joseph's, St. Mary's and St. Agnes' hospitals, Philadelphia, each $1,000 by the will of Charles McElvaney.

Warning.—The readers of The Journal are warned against a man claiming to be J. F. McClure, of the McClure and Freeman Supply Company, Freeman Building, Cincinnati. He claims to represent a cooperative automobile supply company. He is said to have imposed on a number of physicians in different towns in North Carolina. There is no such firm as McClure and Freeman. The man against whom this warning is directed is about 6 feet in height, weighs 170 pounds, has had a left sided facial paralysis, is clean shaven, well dressed, and appears to make a specialty of dealing with physicians.

Armour and Co. to Make Physical Examinations of All Employees.—Armour and Company are planning to renew medical examinations of the 12,900 men and women working in the Chicago plant. This work was discontinued during the war because of the urgency of orders placed to keep the fighting forces supplied with food and the enormous amount of extra labor needed. Dr. Volney S. Cheney and a corps of assistants will have charge of the work. Through their welfare bureau and their staff of doctors the company offers this service free to the workers. In case defects which have interfered with a man's work are brought to light, he is transferred to some other task in the plant which, in the opinion of the medical men, he is better able to perform.

Court Awards Damages for Death Resulting from Anthrax Contracted from a Shaving Brush.—Anthrax contracted from a shaving brush was the cause of a suit recently brought by Mrs. Emma McCarroll Lindsey against the S. H. Kress Company of New Orleans, which was tried in the federal court at Biloxi, Miss. Mrs. Lindsey stated that her husband bought a shaving brush from the Kress Company. While shaving he cut himself slightly and some of the lather from the brush got into the scratch. He soon developed anthrax which caused his death. Evidently the brush was made from the bristles of an animal that had died of the disease, the bristles not having been sterilized and rendered safe before being converted into a shaving brush. Mrs. Lindsey was awarded $6,500 damages.

Aid Asked for Establishment of Siberian University.—In a letter addressed to American and Canadian Men of Science, Prof. W. Boldireff, the distinguished Russian chemist and scientist, appeals for aid in the way of equipment, both scientific and ordinary, including books, funds, instruments, apparatus, furniture, etc., for the establishment of a medical school at Vladivostok to become ultimately a department in a new university in eastern Siberia. He points out that at present science and research have practically been abandoned in Russia except in the Petrograd Military Academy and in the University and Technological Institute at Tomsk. The Petrograd Academy of Science and the Petrograd, Moscow and Kazan universities, with the latter of which Professor Boldireff was connected, have ceased their activities, and their teaching faculties have been scattered. At present there are available for the new school at Vladivostok men sufficient for a teaching staff who have interested themselves with Professor Boldireff in the establishment of an institution for medical and scientific teaching, and it is believed a student body of 250 could be gathered for the opening year, provided the start can be made this year. At present there are neither funds nor equipment of any kind available for the school, and an urgent appeal is made to scientific men of other countries, especially the United States and Canada, to interest themselves without delay in the equipment of the school.

Conference of Red Cross Societies.—With a view of preparing a program to relieve suffering and combat disease in the general interest of humanity, the Committee of Red Cross Societies called a conference of leading medical experts of the world to convene at Cannes, France, April 1. These first conferences at Cannes are preliminary, on the part of the Committee of Red Cross Societies, to formulating and proposing to the Red Cross societies of the world an extended program of Red Cross activities in the interest of humanity. The first conference, according to announcements, undertook to prepare a program dealing with the organization of the International Council and Bureau of Hygiene and Public Health, which will consider the work to be undertaken in connection with the prevention of epidemic disease, tuberculosis, venereal disease and child welfare. Specialists in attendance are the recognized authorities on these subjects. As a result of these conferences a complete program will be made which will deal with the latest and best means to relieve suffering and combat disease. This program will be submitted at a conference of all Red Cross societies to be held in Geneva thirty days after peace is officially declared. The call for this later conference was issued, February 13, by the International Red Cross at Geneva. Announcement of the formation of the Committee of Red Cross Societies was made in Paris about three weeks ago. It has established headquarters at Cannes, with administrative headquarters at 2 Place de Rivoli, Paris. The committee is composed of representatives of Red Cross societies of France, Great Britain, Italy, Japan and the United States, with Henry P. Davison, formerly chairman of the War Council, American Red Cross, as chairman.

FOREIGN

Influenza in Japan.—The statistics at Tokyo show a higher death rate from influenza, according to the *Japan Medical World,* than has been encountered elsewhere. In the last three months there were 5,077 deaths from influenzal pneumonia. This is equivalent to 28.14 per cent. of the total mortality, and 2.16 per thousand inhabitants.

Assassination of Another Physician.—The *Paris Médical* relates that Dr. Kuhne of Geneva, Switzerland, served in a hospital in Serbia during the Balkan wars before and during 1914, and returned with impaired health for which he took a course of treatment at Leysin. Later he gave his services to the Serbian sanatorium at Leysin where he was recently assassinated by an insane Serbian soldier.

Italian Congress for Internal Medicine.—The *Riforma Medica* brings the announcement that the annual meetings of Italian internists, that have been interrupted by the war, are to be resumed. The 1919 meeting is to be held at Trieste, in October, if circumstances permit; if not, it will convene at Rome. Maragliano is president of the executive council for the congress, which is to meet shortly to plan the order of the day for the meeting.

Death of Professor Pel.—For reasons of health, Prof. P. K. Pel recently retired from the chair of clinical medicine at the University of Amsterdam which he has held since 1883. His death is now reported, at the age of 67. He was twice president of the Netherlands Medical Association. His writings on internal medicine have carried his name far and wide, and he has long been a familiar figure at international scientific gatherings.

The Manifesto Signed by German Scientists.—In an editorial in the *Journal de Médecine de Bordeaux*, Cruchet, referring to the famous Manifesto signed by ninety-three leading German scientists, relates that this Manifesto was signed later by hundreds of other scientific professors. By Oct. 16, 1914, it had 3,131 signatures, including twenty from the medical department of the University of Strasbourg, thirty from Heidelberg, and thirty-five from Leipzig. Copies of it were found recently at Strasbourg.

Portugal's Losses During the War.—The *Medicina Contemporanea* of Lisbon quotes some recent statistics, although stating that they are not official, showing that in France 43 officers, 62 noncommissioned officers and 1,236 of the rank and file lost their lives, with a total of 5,626 wounded, 2,982 missing and 7,740 taken prisoner. Portugal lost also on the sea, 28 men, including 4 officers; in Mozambique a total of 2,477, including 25 officers and 1,055 natives; and in Angola a total of 680, including 30 officers and 650 Portuguese soldiers. The medical officers are included in these figures.

Deaths in the Profession Abroad.—Sir **James MacKenzie Davidson,** London, M.B.C.M., Aberdeen, 1882; aged 62; an authority on radiology; consulting radiologist to the military hospitals in London district during the war; inventor of a precise means for the localization by roentgen ray of foreign bodies of the eye, and of the orbit in general; fellow of the Royal Ophthalmological Society; president of the radiological section of the Seventh International Congress of Medicine; died at his home, April 2.——Prof. **Sir William Crookes,** London, one of the most eminent chemists and physicists of the world; aged 86; died at his home in London, April 5. Professor Crookes received his education at the Royal College of Chemistry in London, and in 1861 became assistant professor in that institution. In 1862 he discovered thallium, a new element, and while carrying out investigations of this metal and its properties, utilized a principle thus discovered, in the construction of the radiometer, and this in turn led on to his researches on the phenomena produced by the discharge of electricity through tubes from which air had been exhausted. Later on he conducted researches into the constitution of rare earths with especial reference to radium. He was the author and editor of many works on chemistry and chemical technology, and in later years was much interested in psychic phenomena.

Vaccination Made Compulsory in the Province of Madrid.—The *Siglo Medico* states that a recent decree of the governor of Madrid province makes vaccination against smallpox compulsory throughout the province within thirty days from Jan. 10, 1919. The vaccination will be done free at the seventeen emergency stations and at the municipal laboratory. The alcaldes who fail to organize a vaccination service as ordered will be fined 500 pesetas. No one shall be permitted on the streets and roads of the province without having been vaccinated. They must produce the certificate of vaccination or show the vaccination scar. Pedestrians, persons in vehicles or on horseback who cannot prove that they have been vaccinated must be taken to the vaccinating station. If they resist, a fine of 500 pesetas shall be imposed or a prison term for fifteen days. The alcaldes shall organize a *servicio de vigilancia* in their respective districts. The above fine or arrest shall be enforced also for every private individual or company which admits or retains in its service any employee who cannot show a vaccination certificate. Similar penalties shall be enforced for teachers, heads of societies, hotels, lodging houses, etc., who fail to exact within forty-eight hours a vaccination certificate for all persons in their establishments. The above penalty will be enforced also for forging or fraudulent use of others' certificates. The public health inspector general of the province and his medical subordinates are to visit all the towns to ensure that this decree has been enforced. The only ones exempt from the decree are soldiers and persons presenting a medical certificate to the effect that vaccination is contraindicated in their case.

Reply of the University of Bordeaux to the University of Leipzig.—The University of Leipzig recently sent to the universities of the neutral countries an open letter protesting against the dismissal and banishment within twenty-four hours of the German professors and librarians of the University of Strasbourg. The protest was signed by the dean and senate of the University of Leipzig and bore an endorsement by the University of Heidelberg. It concluded "We beg you to note this open letter and to distribute it to the press of the neutral countries and to send at once a copy to the French, English and American universities and academies of science." The protest was forwarded by the University of Upsala to the University of Bordeaux with the expression of a wish that international relations might soon be resumed between the universities of all countries.

The *Journal de Médecine de Bordeaux* publishes the letter in full, and gives also the reply which the University of Bordeaux sent to the University of Upsala, as follows: "Since you thought it incumbent on you to forward to us the letters from the Universities of Leipzig and Heidelberg, we beg you in turn to give the universities of the neutral countries and the German universities if you think it will serve any purpose (*si vous croyez que cela puisse servir à quelque chose*) an account of the consideration shown by the Germans during their occupation of Lille to the professors, to science and to scientific interests. You will find an account of this in the transactions of our Académie des Sciences. You will find other accounts in the *Revue des Deux Mondes* over the signature of the rector of the University of Lille, as both witness and victim. And you will judge for yourself whether the annoyance of having to move, even rather hastily, is anything to compare with it.

"As to the wish you express in your own name relative to a resumption of relations between universities, we beg all the universities of the neutral countries, and especially the University of Upsala, which has such a high reputation in France, to send delegates to visit the north of France or even just to pass through certain parts of it in the cars. After they have returned from this trip, then you can tell us how long an interval you would allow to elapse before resuming relations with people who had done the same thing to your own country. In our opinion, the generation which has committed these abominations or which, in the Manifesto of which you know, backed up (*s'est solidarisée*) those that did commit them, has cut itself off from humanity. We will talk, if it desires it, with the next generation."

LONDON LETTER

LONDON, March 19, 1918.

Appointment of Whole-Time Physicians at the London Hospital

An entirely new departure in this country is about to be made at the London Hospital by the appointment of whole-time paid physicians. At the quarterly court of the governors, the president, Lord Knutsford, said that the matter had been engaging earnest consideration for a long time. It touched a principle that had governed the work of the sick poor ever since voluntary hospitals existed—the care of the patients by an honorary visiting staff. Under this system, splendid service had been given by the medical and surgical staff, which had spread the reputation of the hospital far and wide; and if medicine and surgery stood today in the position that they did fifty years ago, no improvement could be suggested. Every patient was seen once or twice a week by a man of great experience, and his instructions were carried out by an officer resident in the hospital. That was an ideal arrangement under the conditions that had prevailed. But in the past twenty-five years, discoveries had been made which had revolutionized treatment—the roentgen ray, vaccines and antitoxins, and scientific knowledge had advanced with regard to the chemical processes of the body, the blood and of the blood pressure, the functions of nerves in relation to pain and to the mind, and how these functions were affected by disease. The cure and prevention of disease had become subjects for advanced technical knowledge and of continuous study. There was no question of changing the present honorary staff for a paid and whole-time staff; but two vacancies, due to the retirement of Dr. Head and Dr. F. J. Smith, had occurred. Instead of appointing new members to the honorary staff, whole-time officers would be appointed. Under the new arrangement, the "firm" would consist of a director, three clinical assistants, and laboratory and clerical assistants. All of these would be engaged for the whole of their time and would be paid for their services. It was to be understood that this was not simply a teaching unit. It was a unit which would have to carry out precisely the same work as other members of the hospital staff. The members of this unit would give their whole time to curing disease, research on the causes of disease, and the education of the medical students. A very important part of their duties would be researches into the early causes of disease. If the scheme proved to be advantageous, it might be repeated as vacancies occurred. It might also be that whole-time units of very special departments, such as dermatologic, syphilologic, gynecologic, orthopedic and genito-urinary, might be formed on somewhat similar lines.

The War and Mental Disease

In his annual report on the Royal Edinburgh Mental Hospital, the superintendent, Dr. G. M. Robertson, deals with the mental effects of the war. He says that the public anxieties connected with the varying fortunes of the war have not caused much insanity. The mental breakdowns that were due to these causes have been more than counterbalanced by a diminution in other directions. The war was an event of such absorbing interest that it distracted many from their introspective habits and personal worries, and it thus acted as a protection to them. Even if there was public gloom it did not touch the individual like a private sorrow. for the former is not only more remote, and cuts less deeply but there is an excitement associated with it which acts like a mental stimulant. The effects due to private griefs and losses have been much more serious, and of course the appalling conditions of modern warfare have been a terrific strain on the nerves of the combatants. Dr. Robertson looks forward with great apprehension as to what the effects of these serious recurring outbreaks of influenza will be on the mind and nerves of those who have already suffered much. Short of producing actual mental disorder, the extraordinary economic conditions experienced during the war have had a very unsettling effect on many. A psychologic factor that operates in fomenting the labor unrest that exists has not yet been referred to by any one. It is a remarkable fact how many young men who were exempted from military service, and earned high wages in comfort and safety at home, are taking a leading and active part in these disturbances. They believe that they are actuated by altruistic motives, and are fighting solely for the rights and welfare of the class to which they belong; but how much of their action is really due to the uneasiness and unrest in their own minds? Just as it sometimes happens that a great swindler throws himself into church work to stifle the reproaches of his conscience, so these men who shirked fighting for their country ease their minds of this painful knowledge, and protect their injured feelings of self-respect by the thought that they are nobly doing their bit by now fighting for their fellow workers. This is a mental process for defense purposes known as inversion. How different the state of contentment and the peace of mind of the severely wounded. They know they have done their duty by their country and feel that every one else thinks so too. The hero instincts are distressing the one class while comforting the other.

Vital Statistics: More Deaths than Births

The report of the registrar-general for the last quarter of 1918 is of unusual interest. For the first time since the establishment of registration, the number of deaths exceeded the number of births. The excess was 79,443. The average excess of births over deaths in the fourth quarter of the three preceding years 44,785. This serious condition must be viewed in the light of the influenza epidemic, to which no fewer than 98,998 deaths, or 41 per cent., of the total deaths the the quarter are attributed. Influenza, however, does not becately account for the fact that the relation between the forces rate and the death rate is *not* improving. The birth labor n the last quarter of 1918 was the lowest on record.

will hav

and their

Supply of Medical Students

to the wccs furnishkd by the General Medical Council show a man's workable increase has taken place in the number of other task ihnts. The total number in attendance in January men, he is betris compares with 7,630 in May, 1918; 7,048 in and 6,682 in January, 1917. Further analysis of the figures shows that in January last there were 6,798 men and 2,692 women students. The first year students numbered 2,152 men and 755 women. The contrast of these totals with the numbers of students in the final year of their curriculum is striking. It is due, of course, to the disturbing effect of the war. In the latter category there were only 936 men and 226 women.

Statistics of Venereal Disease

In a popular lecture on venereal diseases at Gresham College, Sir Robert Armstrong Jones, lecturer on psychologic medicine to St. Bartholomew's Hospital, stated that it had been definitely ascertained that 2 per cent. of the army, or over 100,000 men (some said a quarter of a million), were infected with venereal diseases. In the civil population at least 2 per cent. were infected. Out of 800,000 infants born yearly in England and Wales, 100,000 died before the end of the first year. Of these, a very large number died from inherited syphilis. He hoped that the new education act, which carries on compulsory training to the age of 16, would greatly facilitate the understanding of the dangers, and that no boy or girl would leave school without receiving some warning of the great risks of immorality.

PARIS LETTER

Paris, March 9, 1919.

The Radio-Surgical Aeroplane

Speaking of the new use to which the aeroplane has been put, it is suggested that the "Aerochir" might also be used to aid in times of peace in case of catastrophe, railroad accident, or explosion, occurring at remote points and where surgical assistance should be given as soon as possible. This surgical aeroplane was described in The Journal, Oct. 12, 1918, p. 1252. It will find its greatest sphere of usefulness in the colonies or other sparsely settled regions.

The Medal of the Lariboisière Hospital

The city of Paris recently dedicated a tablet commemorative of the medal of honor which the Assistance publique awarded to the Lariboisière Hospital last year. M. Brisac, directeur de l'Assistance et de l'Hygiène Publiques au ministère de l'intérieur, took part in the ceremonies at which were present delegates from all the hospitals of Paris. The medal was awarded in tribute to the courage and the devotion of the physicians, interns and nurses during the catastrophes from bombs and bombardment.

Organized University Rapprochement

The "Rapprochement universitaire," presided over by M. Larnaude, dean of the law department of the University of Paris, recently tendered a reception at its social headquarters to American professors and students now residing in Paris. M. Henri Bergson, speaking in French and in English, welcomed the large number of members of the teaching corps who had responded to the invitation of the "Rapprochement universitaire." He stated that the work accomplished thus far by this organization has been of great value and will prove more so in the future. He extended thanks to the many students of American universities who had fought in France for the cause of right and liberty, many of whom were present at the ceremonies.

Professor Nettleton recalled that fourteen months ago the Comité du rapprochement universitaire had informed the Comité exécutif de l'union universitaire américaine in Europe of its intention to organize at the Sorbonne a gala fête in honor of the students of the American universities who had come to France to fight a common enemy. The German offensive had made it necessary to delay this project until a more favorable time.

State Aid for Sanatoriums

The Chamber of Deputies recently passed a bill which provides for the establishment of special sanatoriums. The object proposed is to associate the government with all the provinces, communities, public and private institutions and associations in the work of establishing sanatoriums for the treatment of pulmonary tuberculosis. The state will share in the cost of construction, equipment and maintenance.

Reorganization of the Medical Service in the Merchant Marine

At the suggestion of M. Bouisson, high commissioner of the transports maritimes et de la marine marchande, the Academy of medicine appointed a committee to investigate the possibilities of the reorganization of maritime medical service. This commission having examined official documents and having been addressed by Dr. Reynès, president of the Syndicat de médecine sanitaire maritime de France, has decided in favor of the autonomy and independence of this service, and has suggested the creation of a new Corps des médecins de la marine marchande, to be appointed by competitive examination and to be paid by the state.

Second Congress of Pediatrics

During the week of April 20 to 27 a congress on pediatrics will be held in Paris. This congress was originally scheduled to take place at Lyons in October, 1914. The committee appointed at that time still has charge of the arrangements for the congress, with Professor Weill of Lyons as chairman.

Military Medal Presented to a Physician

Dr. Jean Meyer, sous-aide-major has been decorated with the military medal because of his devotion, professional ability and military spirit. He had been attached to a combatant unit for thirty-nine months, took part in many large battles, and has received nine citations. He was wounded once.

Personal

The following have been made members of the Commission supérieure de l'enseignement médical: Dr. Hartmann, professor of clinical surgery in the Paris medical faculty; Dr. Arnozan, professor of clinical medicine on the Bordeaux medical faculty; Dr. J. Lépine, associate professor in the Lyons medical faculty, and Dr. Alezais, director of the Marseilles school of medicine and pharmacology.

The Academy of medicine elected Dr. E. C. Achard, professor of pathology and general therapeutics on the medical faculty of Paris, to succeed Dr. Raphael Blanchard in the post of secretary. Dr. Louis Martin, physician in the Pasteur Hospital, was elected a member of the section on therapeutics and natural history, vice the late Dr. Bureau.

Deaths

Dr. Henri Hallopeau, associate professor in the Paris medical faculty and honorary physician to the Saint-Louis Hospital, is dead, aged 78 years. He was born in Paris in 1842 and began his studies at the Bonaparte Lyceum, now known as the Condorcet Lyceum. In 1866 he became a hospital intern, and received his doctorate in 1871. A little later he became medical attendant at the hospital, and then professor agrégé. Dr. Hallopeau specialized in dermatology and syphilography. He contributed much to the reputation of the famous school of the Saint-Louis Hospital, and was among those who revised syphilitic medication. He studied all the forms of dermatoses, notably the tuberculids, lupus, and leprosy, and in 1901 he called attention to the great danger from these diseases to which European countries were exposed, particularly France. In 1904 he published a Treatise on General Pathology and in 1900, in collaboration with Leredde, a Practical Treatise on Dermatology. He had been a member of the Academy of Medicine since 1893.

Dr. Victor Chaput, surgeon at the Lariboisière Hospital, died recently, aged 56 years. A year ago he lost his son, an aviator of repute, who was killed in aerial combat after having brought down his sixteenth enemy aeroplane.

Dr. Beni-Barde, celebrated specialist in hydrotherapy, has just died, aged 83. He was a member of the Société de médecine de Paris and of the Société d'hydrologie, and was the author of numerous works, especially a Treatise on Hydrotherapy, which became an authority.

Marriages

William Barclay Terhune, Jr., Lieut., M. C., U. S. Army, New Orleans, on duty with U. S. Army General Hospital No. 2, Fort McHenry, Md., to Miss Jane Denham of Boyceville, Wis., March 19.

William Barclay Parsons, Jr., Lieut., M. C., U. S. Army, New York City, to Miss Rose Saltonstall Peabody of Groton, Mass., March 22.

Elwyn Dene Price, Silver City, N. M., to Miss Ida Mae Heminger of Fort Madison, Iowa, at Las Vegas, N. M., December 20.

Mary Jane McFall, Somerset, N. S., to Mr. Hugh McKinley Nesbitt of Tompkins, Sask., February 20.

John Bell Matthews, Milwaukee, to Miss Katherine I. Robinson of Terre Haute, Ind., March 8.

Deaths

Daniel Lewis, Alfred, N. Y.; College of Physicians and Surgeons in the City of New York, 1871; aged 73; a member of the Medical Society of the State of New York, and president from 1884 to 1886; vice president of the New York Academy of Medicine in 1896; medical director for New York in the Grand Army of the Republic in 1888; commissioner of health of the state of New York from 1882 to 1894; consulting surgeon to the Dobbs Ferry Hospital, and consulting physician to the Baptist Home, Alfred; a veteran of the Civil War, in which he served in the United States Navy; a specialist in surgery; died at his home, March 22.

Frank Van Fleet ⊕ New York City; Bellevue Hospital Medical College, 1881; aged 58; a member of the New York Academy of Medicine; president of the board of surgeons of the Manhattan Eye, Ear and Throat Hospital, and formerly president of the New York County Medical Society; consulting ophthalmologist to the Park Hospital and the House of the Good Sheperd; consulting ophthalmologist to several government hospitals caring for wounded soldiers; died suddenly in his office, April 5, from heart disease.

Jeremiah E. Finch, Port Rowan, Ont.; Toronto School of Medicine, 1854; aged 89; surgeon of the Seventh Minnesota Volunteer Infantry during the Civil War; president of the Minnesota State Medical Association in 1878; mayor of Hastings, Minn., in 1886, and president of the local board of education from 1871 to 1884; died at his home, March 2, from senile debility.

Charles Nahum Haskell ⊕ Bridgeport, Conn.; University of Vermont, Burlington, 1890; aged 57; attending neurologist and chief of the outpatient clinic of St. Vincent's Hospital, Bridgeport; formerly attending physician at the Emergency Hospital, and city physician of Bridgeport; died in Roosevelt Hospital, New York City; March 5, from angina pectoris.

Chelius S. Pixley, Los Angeles; University of Wooster, Cleveland, 1871; aged 70; demonstrator of anatomy in his alma mater in 1872 and 1873; local surgeon of the Lake Shore and Michigan Southern Railway at Elkhart, Ind., from 1873 to 1890; once president of the Elkhart County (Ind.) Medical Society; died at his home, March 21.

William Cheatham ⊕ Louisville, Ky., 1873; aged 66; professor of the eye, ear, nose and throat in his alma mater for many years and later emeritus professor; physician to the Masonic Home, Episcopal Orphanage, and Presbyterian Orphanage Hospital, Louisville; died at his home, April 3, from angina pectoris.

Frank Finney ⊕ La Junta, Colo.; Georgetown University, Washington, D. C., 1882; Bellevue Hospital Medical College, 1885; aged 50; since 1899 chief surgeon of the Santa Fe Railway Hospital at La Junta; at one time president of the Colorado State Medical Society; died at his home, March 23, from angina pectoris.

James Meek Caldwell, Gastonia, N. C.; Medical College of the State of South Carolina, 1885; aged 57; a member of the Medical Society of the State of North Carolina; for several years a member of the staff of the State Hospital for the Insane, Columbia, S. C.; died at his home, March 2, from heart disease.

James J. Clark, Washington, D. C.; New York Homeopathic Medical College, New York City, 1869; aged 90; inventor of several telegraphic devices, including the closed circuit repeater; a contemporary of Samuel Morse; died at his home, March 21, from pneumonia following influenza.

Newton C. Steele, Chattanooga, Tenn.; University of Nashville, Tenn., 1873; aged 69; a member of the Tennessee State Medical Association; professor of diseases of the eye, ear, nose and throat in the Chattanooga Medical College; died at his home, March 19, from pneumonia.

Wallace Clarke, Utica, N. Y.; McGill University, Montreal, 1871; aged 69; a member of the Medical Society of the State of New York; for several years health officer of Marquette, Mich.; a specialist in diseases of the eye, ear, nose and throat; died at his home, March 16.

Richard D. Shannon, Sedalia, Mo.; Jefferson Medical College, 1868; aged 76; for several years superintendent of schools of Joplin and Lousiana, Mo.; once president of the University of Missouri; died at the home of his daughter in Sedalia, March 18.

⊕ Indicates "Fellow" of the American Medical Association.

Nicholas Emery Soule, Exeter, N. H.; University of Pennsylvania, Philadelphia, 1851; aged 93; a member of the United States Sanitary Commission during the Civil War; for many years a teacher in private schools in Cincinnati; died at his home, March 26.

Edgar Cole, Holmesville, Ohio; Eclectic Medical College of Pennsylvania, Philadelphia, 1872; American University of Pennsylvania (Eclectic), Philadelphia, 1873; aged 76; a member of the Ohio State Medical Association; died at his home, January 10.

George L. Parr, Washington, Ind; University of Louisville, Ky., 1874; aged 71; a member of the Indiana State Medical Association; died in the Good Samaritan Hospital, Vincennes, Ind., March 27, a few hours after a surgical operation.

Frederick Robinson Smith, Rochester, N. Y.; Hahnemann Medical College, Philadelphia, 1893; aged 48; coroner of Monroe County, and president of the New York Motor Federation; died at his home, March 25, from pneumonia.

Frank Thomas McGuinn, Chicago; Northwestern University Medical School, Chicago, 1909; aged 33; was killed by the overturning of his automobile, near the boundary line between Evanston and Chicago, March 29.

Luke P. Davidson, Hollywood, Ark. (license, Arkansas State Eclectic Medical Board of Examiners, 1908); aged 37; died in his room in a hotel in Little Rock, March 23, it is believed, from the effects of poison.

William Chapman, Seattle; Northwestern College of Bio-Chemistry, Spokane, Wash., 1889; aged 83; a member of the city council of Seattle for four years; died at his home in Laurelhurst, Seattle, March 24.

Harold Montgomery Craig ⊕ Capt., M. C., U. S. Army; Detroit College of Medicine and Surgery, 1911; aged 30; on duty at Fort Stevens, Ore.; died at that post, October 8, from pneumonia following influenza.

Harry Gustave Lundgren, Ironwood, Mich.; University of Michigan, Ann Arbor, 1918; aged 25; a member of the staff of the University Hospital, Ann Arbor; died in that place, March 24, from pneumonia.

George Francis Lewis, Collinsville, Conn.; Yale University, New Haven, Conn., 1865; aged 78; a member of the Connecticut State Medical Society; died at his home, February 25.

John G. Walthall, Gas City, Ind.; Medical College of Indiana, Indianapolis, 1885; aged 64; health officer of Gas City; died at his home, March 27, from heart disease.

John M. Rowe, Charleston, Mo.; University of Nashville, Tenn.; 1869; aged 77; a Confederate veteran; died at his home, January 2, from pneumonia following influenza.

Walter H. Kremer ⊕ Germantown, Philadelphia; University of Pennsylvania, Philadelphia, 1894; aged 58; died at his home, March 15, after an operation for appendicitis.

Samuel Ellsworth Bailey, Berkeley, Calif.; University of California, San Francisco, 1912; aged 31; died at his home from the effects of an accidental gunshot wound.

John H. Bowman ⊕ Berwick, Pa.; University of Pennsylvania, Philadelphia, 1888; aged 60; died at his home, March 15, from chronic nephritis.

Daniel H. Braman ⊕ Victoria, Texas; Tulane University, New Orleans, 1890; aged 53; died at his home, March 15, from cerebral embolism.

Robert Francis Gross, Weir, Texas; University of Louisville, Ky., 1906; aged 50; died at his home, January 6, from pneumonia.

Francis H. Sinning, Titusville, Pa.; American Eclectic Medical College, Cincinnati, 1885; aged 63; died at his home, March 15.

Reuben Gross, Eureka, Calif.; University of Glasgow, Scotland, 1862; aged 87; died at his home, March 13, from senile debility.

Asa S. Ashton, Piqua, Ohio; Jefferson Medical College, 1864; aged 86; died at his home, February 21, from senile debility.

Charles Leo Ebnother, Downs, Kan.; State University of Iowa, Iowa City, 1883; aged 65; died at his home, March 12.

John Fitzhugh May ⊕ Waverly, Va.; Jefferson Medical College, 1881; aged 51; died suddenly at his home, March 18.

James C. Ford, Santa Cruz, Calif; Missouri Medical College, St. Louis, 1859; aged 80; died at his home, February 12.

Frank Chester Fowler, New London, Conn. (license, Connecticut, 1893); aged 59; died at his home, March 19.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

COLLOSOL COCAINE NOT ADMITTED TO N. N. R.

Report of the Council on Pharmacy and Chemistry

The report which appears below was adopted by the Council and sent to the Anglo-French Drug Co., Ltd., New York, for comment in December, 1918. No explanation has been received from the manufacturer. For the information of the profession the Council has now authorized publication of the report.

W. A. Puckner, Secretary.

"Collosol Cocaine" was submitted to the Council in October, 1918, by the Anglo-French Drug Co., Ltd., New York, under the claim that it was an "absolute colloid" and that it contained "1 per cent. cocain." The label on the submitted specimen declares:

> "Collosol Cocaine 1-100"
>
> ". . . the Cocaine exists as the pure alkaloid in the Colloidal state—the condition in which it is isomorphic with the protein of the body fluids. The effect is more prolonged than that of a molecular Cocaine Solution and being *non-toxic* absorption presents no practical danger."

The product was assigned to the Committee on Pharmacology for consideration. The following report was submitted and its adoption by the Council recommended by the committee:

> "Collosol Cocaine" is said to be a colloidal form of cocain and is alleged to possess a remarkably low toxicity. The subjoined report of the A. M. A. Chemical Laboratory, however, shows that the preparation does not have the composition claimed for it and it is, in effect, misbranded. In fact the English manufacturers concede that it is not an "absolute colloid" and that the declaration with regard to the percentage of cocain is incorrect.
>
> It is recommended that, without considering other conflicts with the rules of the Council at this time, "Collosol Cocaine" be declared inadmissible to New and Nonofficial Remedies for conflict with Rule 1 which requires that the composition of an article must be correctly declared. The report of the A. M. A. Chemical Laboratory is appended.

REPORT OF THE A. M. A. CHEMICAL LABORATORY

Simpson, Hewlett, and Eyre (*Lancet*, April 28, 1917, p. 600) reported "Collosol Cocaine" to be much less toxic than cocain. These writers, however, did not verify the statements as to composition and in the light of subsequent chemical examination it is not to be wondered at that "Collosol Cocaine 1.0 per cent." was much less toxic than a solution containing 1.0 per cent. of cocain hydrochlorid.

Barger, Dale and Durham report from the Department of Biochemistry and Pharmacology, Medical Research Committee (*Lancet*, Dec. 1, 1917, p. 825), that they examined "Collosol Cocaine" and found it to contain but 0.25 per cent. of cocain. They also found that the cocain was not present in a colloidal form. Discussing the low toxicity claimed by the manufacturers, these investigators state:

> "In the samples which we examined the toxicity was, indeed, much lower than that of an ordinary 1 per cent. solution of a cocain salt; but the local anesthetic action was low to a corresponding degree, and both actions corresponded satisfactorily with the proportion of cocain chemically recoverable from the solution."

Stroud, of the Crookes Laboratory (which manufactures the preparation), who apparently had been informed of this work in advance of publication, admits the correctness of it and states (*British Medical Journal*, Nov. 24, 1918, p. 71) that "whilst the colloidal protective apparently absorbs a portion of the cocain, the remainder is found *not* to exhibit the attributes of a colloid. . . ."

The specimen of "Collosol Cocaine" submitted to the Council and labeled "Collosol Cocaine 1-100" was found to contain at most 0.4 per cent. cocain. The examination was made in accordance with the method used by Barger, Dale and Durham and calculated as cocain. This method, however, probably would not distinguish between cocain and basic decomposition products, but would include all as cocain in the amount found. The specimen of "Collosol Cocaine" examined was neutral or slightly acid, a fact which tends to confirm the conclusion of the British investigators that "Collosol Cocaine" contains cocain in noncolloidal form and precludes an increased physiologic effect due to alkalinity.

The Council adopted both the report submitted by the committee and also that of the A. M. A. Laboratory and declared "Collosol Cocaine" inadmissible to New and Nonofficial Remedies.

CUPRASE NOT ADMITTED TO N. N. R.

Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following report on Cuprase, sold by the Anglo-French Drug Co., Ltd. The Council's criticisms of the advertising claims were sent to the firm, December, 1918. The firm made no reply and essentially the same claims are contained in recent advertisements.

W. A. Puckner, Secretary.

"Cuprase" is now being advertised and sold in the United States by the Anglo-French Drug Co., Ltd., the firm which also markets it in England. It is said to be "prepared in the Laboratories of F. Ducatte, 8 Place de la Madeleine, Paris." According to an advertising circular entitled "The Medical Treatment of Cancer" "Cuprase" is "chemical colloidal copper"; in another place it is "a colloidal copper hydroxid," which is said to be obtained chemically by the reduction of salts of copper in the presence of albumosic acid.

A box (price $8.50 less 10 per cent. discount) of "Cuprase-Doctor Gaube du Gers" was purchased recently from the Anglo-French Drug Co., Ltd. It contained eight ampules each containing approximately 6 c.c. of a brownish fluorescent liquid. No information of composition was given on the box, except the line: "Chaque ampoule contient: 0 gr. .00121 de Cuivre pur" (Each ampule contains 0.00121 gr. of pure copper). The A. M. A. Chemical Laboratory reports that the preparation does contain a small amount of copper, with some protein material and about 1 per cent. sodium chlorid.

The therapeutic claims in the advertising circular are those commonly made for cancer "cures" and are about equally convincing. The publication of such statements and quotations as the following, which appear in a pamphlet "The Medical Treatment in Cancer," cannot be too strongly condemned in a medicament that at best has only an experimental status:

> "A special preparation, Cuprase, has been introduced into therapeutics which has been remarkably successful. In the history of the therapeutics of cancer, nothing has been found which can compare with the effects produced by means of Cuprase. Clinical facts carry greater weight than theoretical deductions. It follows, from the clinical observations which I have collected, that in the large majority of cases Cuprase effects the diminution or disappearance of the pains, an improvement in the general condition, a diminution or arrest of the neoplasms, and finally in certain cases, a cure has been effected. It should be remarked that all or nearly all the observations refer to inoperable cases in which the prognosis was unfavorable at an early date. It is needless to emphasize the practical importance of a preparation capable of yielding such results, even relative, in the worst stages of a disease which has always been regarded as absolutely resisting the action of all internal remedies."
>
> "To sum up, Cuprase has given positive results in about 94 per cent. of the cases in which it has been employed for a sufficiently long period, and some brilliant results in about 20 per cent. of these cases. Therefore, it may be affirmed, that among the internal remedies for cancer, Cuprase is the one which has produced the most successful results, and can, under certain circumstances, compete with surgical methods, even, so far as the rapidity of their results are concerned."
>
> "It is indicated:
>
> (a) apart from all operation, and as a specific and curative remedy;
> (b) before an operation, in order to give tone to the patient, mobilise the tumour, destroy its toxins;
> (c) after the operation, as a tonic and anti-toxic, and in order to avoid frequent relapses which are always possible."

Essentially the same statements are made in the more recent advertisements (f. i. Urological and Cutaneous Review, Feb., 1919). Opposed to these loose statements are the results of Richard Weil (The Journal A. M. A., 1913, Sept. 27, p. 1034; ibid, 1915, April 17, p. 1283). Weil avoided pitfalls of subjective impressions and used as the essential criterion of efficiency "the demonstrable reduction in size of a tumor, of a kind not to be attributed to the natural processes of evolution of that tumor or of its associated lesions" (l.c. 1915, p. 1289).

The available evidence for Cuprase is far from meeting this criterion. That published by the manufacturers and agents presents only vague generalities, and no definite data. The evidence gathered by Weil himself permits an estimate of the value of Cuprase and it is entirely unfavorable. He states (l.c. 1915, p. 1288):

> "Colloidal copper has been used in recent time for the same purpose by Gaube du Gers and by others. I have recently examined the effects of colloidal copper on malignant tumors in man, and have been unable to find that it has any therapeutic value. Furthermore, a study of the distribution of the copper in tumors obtained at operation or by necropsy from individuals so treated failed to show that the copper had been deposited therein."

In view of the extravagant and cruelly misleading therapeutic claims, and the indefinite statements of composition, the Council voted Cuprase ineligible to N. N. R., and authorized the publication of this report.

"THE NEEDS OF MEDICAL EDUCATION AS REVEALED BY THE WAR"

[Note.—See article with this title, this issue, page 1050, and editorial, page 1076.—Ed.]

To the Editor:—At the fifteenth annual conference of the Council on Medical Education of the American Medical Association, convened in Chicago, March 3, 1919, I listened with intense interest to a paper under the title quoted above. This paper was written by Brig.-Gen. Edward L. Munson, M. C., U. S. Army, and was read before the conference by Brig.-Gen. F. A. Winter of the same corps. I presume that this article has official sanction and is an official statement of the experience which the regular medical corps has had with the reserve corps in the war. General Munson's conclusions are based on a large number of examinations carried out in the medical officers' training camps. The men coming from civilian life, according to General Munson, represented the better part of the civilian profession. He says:

"The medical officers who finally reached the medical training camps represented better than the average of the medical profession of the country, for these candidates had been subjected to several processes of elimination:

"(*a*) They had to be invited to appear for examination by the Surgeon-General, and unless they appeared to be probably desirable, this invitation might not be forthcoming.

"(*b*) They had to be graduates of reputable medical colleges, which ordinarily eliminated men coming from institutions of poor character.

"(*c*) They had to be licensed to practice in the state in which they lived, which would exclude medical graduates who had been found later to be not thoroughly qualified.

"(*d*) They had to be in the active practice of their profession, thereby excluding the failures in medical practice who were making their living by some other vocation.

"(*e*) They had to pass an examination before a local board, which had to be satisfied with their professional, physical and moral qualifications. Here occurred the greater number of rejections, for the local board not only was in a position to test out qualifications by examination, but in many instances it knew the candidate personally or by reputation, and was well informed as to his antecedent activities and conduct.

"(*f*) Before they were commissioned, the American Medical Association investigated and reported on their cases, to make sure that there was nothing in their career that should render undesirable their appointment as medical officers.

"(*g*) Finally, the Surgeon-General had the right of rejection, which was exercised in the case of men who ultimately appeared from their papers to be not qualified for the service.

"Thus a large proportion of the undesirables were excluded from service, and never reached a medical training camp which dealt with an already selected class. That this selected class presented still further professional deficiencies invites reflection on the part of all those in charge of medical education."

As one who has given the greater part of his life to medical education, I have been deeply impressed by General Munson's paper, and especially by the last sentence in the quotation given above, and the purpose of this letter is to induce General Munson to give further information concerning his experience with the reserve medical officers. If the best medical schools in this country are turning out the poor product indicated in General Munson's paper, it is high time that those responsibly connected with these schools should recognize it. For the results reached by General Munson after his experience with this hand-picked body of civilian doctors, the reader is referred to a full abstract of General Munson's paper, published in The Journal, March 15, 1919, p. 822.

Suffice it to state here that General Munson found such a large percentage of these selected civilian physicians unfit, not for merely military duty, but for professional service, that the result is quite discouraging to medical educators who have labored under the delusion that competent practitioners predominated among their graduates. Will General Munson give us further information, in order that medical teachers may profit by his criticism, and make an honest endeavor to remedy some of the most glaring deficiencies? I am asking General Munson to answer the following questions, with such elaboration on each as he may choose to make, for the benefit of myself and others engaged in teaching medicine:

1. What was the percentage of reserve medical officers who served as chiefs of the professional services in the base hospitals in this country and in France? In what respects did these chiefs of service fail professionally?

2. What was the percentage of reserve medical officers in the staffs of the base hospitals in this country and France, below the grades of chief of service? How many of the total serving in this capacity were regular, and how many reserve officers? Wherein did the reserve officers show their professional inferiority to regular officers?

3. What was the percentage of reserve medical officers, compared with total medical officers, who served in the field, especially on the active battle fields of France? What was the proportion of reserve medical officers killed and wounded on the battle fields of France, compared with total medical officers killed and wounded?

4. What was the percentage of the total medical service rendered our soldiers, which was performed by reserve corps men, and wherein did reserve officers show their inferiority to regular medical officers in this service?

As I read General Munson's paper, it is an official condemnation of the professional attainments of the hand-picked civilian medical men. He painstakingly points out that the men, on an examination of whom his opinion is based, were selected and represented the best in the civilian profession. I am not questioning the fairness of General Munson's statements, or the correctness of his conclusions. As the dean of a medical school which furnished from its graduates hundreds of medical men to the reserve corps, I would like to know more fully wherein, and in what particulars, my former students have failed: not as military men, because they have had no training along this line, but in their professional attainments. The purpose in asking for this information is that it may enable me and other medical educators to either attempt to make a radical improvement in the methods and scope of medical education, or to give it up altogether in despair. I am sure that General Munson can render medical educators in this country, and the profession in general, a great service by pointing out wherein our medical education is deficient, and suggesting methods by means of which it may be improved.

Victor C. Vaughan, M.D., Ann Arbor, Mich.

The letter of Dr. Vaughan was submitted to Colonel Munson who replies:

To the Editor:—Relative to the letter by Colonel Vaughan, referring to a paper by me on "The Needs of Medical Education as Revealed by the War" based on the abstract of the original paper (The Journal, March 15, 1919, p. 822), it is believed that the paper itself, in full, will probably give the further information desired by him and perhaps others. However, certain points may here be briefly touched on for further clearness.

In the first place, the general qualifications of the great majority of medical men entering the service were good. To say that all were good would be untrue. To enumerate merely the good qualities would avoid the requirements of the above mentioned subject, assigned me. The paper does not represent criticism. It is an effort to make a diagnosis of a symptom-complex apparently presented by the professional body and to suggest a remedy. Possibly both the interpretation of the symptoms and the remedy are faulty; but the paper serves its purpose if it draws the attention of such sound thinkers as Colonel Vaughan to what may be opportunities of further usefulness in the betterment of the profession.

In replying to his letter, a copy of which he kindly sent me, it may be well to state that the examinations were conducted, except perhaps for the brief period of a very few weeks at the outset of the war, and on a wholly insignificant number of new officers, entirely by temporary officers of the Medical Corps. In the examinations held by them in camps, the examining boards were composed of experts in the civil life from which they came and to which probably most or all have already returned. Any findings they made are thus the findings of the civil profession in uniform in respect to its own members. I myself found no one unfit, as might be inferred from Colonel Vaughan's letter, but merely happened to be asked to express the conclusions reached by the representatives of the profession above mentioned.

It would seem that some of the categorical questions propounded by Colonel Vaughan do not relate to the subject of the paper. I can only say that when the vast majority of medical officers of all services demonstrated their efficiency and patriotism in whatever fields of duty fell to their lot, comparison is unnecessary. There is glory enough for all in the achievements of those who composed the Medical Service of the Army.

I am afraid that Colonel Vaughan tends to reason from the particular to the general when he says that he interprets my paper as "an official condemnation of the professional attainments of the hand picked civilian medical men." Such, of course, was neither possible nor intended. But its purpose was to point out the possible nature and location of the scattered sources of what appears to be professional weakness, so that the eminent leaders of professional education and thought in this country, of which Colonel Vaughan is such a distinguished exponent, may, as they see fit, institute inquiry of their own into the matter of fact and remedy. Sometimes the impersonal point of view of an outside observer affords another opportunity for estimate.

Of course, it is not possible at this time for me to comply with Colonel Vaughan's request to state explicitly wherein the former students of his school have failed. I do not know that any have failed. In a school of the high standards which have been set by him, the proportion of men found not well qualified by the military examining boards would presumably be relatively very small. That a certain few of such graduates, even though originally qualified, may have later lacked such ambition or opportunity as might cause them to lag in the march of progress is perhaps also true.

That the medical profession still has its imperfections will be admitted by all conversant with the matter. During the last fifteen years a professional house clearing has been carried out in respect to medical educational institutions, and professional standards have been elevated. Some of the faults mentioned in my paper, especially of the more elderly men, are relics of this darker professional era. Time will solve this phase of the problem.

But there are other points in which defect would seem to be apparent. These defects are those recognized by every physician who attends medical society meetings. He recognizes that there is a certain proportion of their membership that does not come up to desirable professional standards. The war, by stripping away individual environment and placing all on the general level, has more clearly revealed these professional inequalities. The examining boards in the training camps brought them into strong relief.

Colonel Vaughan asks for information as to how these inequalities may be remedied. He and the other eminent medical men who have made such matters their life study are far better qualified than I am to work out the answer sought. But if there are divergences, and some tend to dip below the proper standards of professional competence, recognition of this fact necessarily implies the duty of attempting betterment by all interested.

Accordingly there are certain matters of such general nature that even I might venture an opinion on them. All are touched on in the original paper, and the following is merely a summary. It is therefore suggested:

(*a*) That all candidates for matriculation for the degree of Doctor of Medicine be given psychologic tests to determine their possession of mental qualities suitable for effectively taking up such an exacting science. These tests are now being employed in the hiring of artisans, clerks, etc., with a view to determining probable efficiency in their less scientific vocations.

(*b*) That medical schools whose curriculums still appear substandard or imperfect institute proper remedy.

(*c*) That such measures be taken as may be possible to insure that practitioners shall not unduly retrograde professionally after graduation. Some influences operating to interfere with keeping up with professional progress are personal problems, relating to initiative, finance, environment or other matters. Others may be favorably affected through medical societies, meetings, etc. The encouragement of the profession, and especially of the less well equipped type, to take postgraduate courses of study at periodic intervals would be very valuable.

(*d*) That more exact standards of qualification in certain important specialties be required, and that those be recognized by special degrees or certificates, as is now the case, for example, with the Doctor of Public Health degree.

These suggestions do not imply anything impracticable. No one knows the mental attainments of the medical profession better than Colonel Vaughan, and I am sure that the matter of the acceptance of such suggestions, in whole or in part, may be safely left to him and his distinguished colleagues in medical education in this country.

EDWARD L. MUNSON, M.D., Washington, D. C.
Brig.-Gen., M. C., U. S. Army.

PROTEST INCREASE IN TAX UNDER NARCOTIC LAW

To the Editor:—It seems that another outrage is about to be perpetrated on the medical profession of this country. I am in receipt of a demand from the collector of internal revenue for this district for the payment of $1.50 for a narcotic license for the period from Jan. 1 to June 1, 1919. I have already paid for and secured a license covering the same period, and would like to know what power and authority they have to demand the payment of an additional tax. I have written the Internal Revenue Office propounding the following queries:

1. Is this license canceled by the act of Congress assessing the additional tax?

2. If so canceled should I not receive credit for the amount of tax already paid?

3. If not canceled, why the demand for the purchase of an additional license?

Something should be done to protect the interests of those who responded to the call to assist the nation in her hour of need and who are now compelled to start anew in the practice of their profession.

O. F. MILLER, M.D., Byesville, Ohio.

To the Editor:—The recent increase in the tax required of physicians under the Harrison act is simply another example of what the profession has submitted to in the last few years. It is presumed that when a man is given a license to practice medicine he is competent to do so. The Harrison act practically denies that inference and imposes on the profession a tax before we can use certain drugs. Foolishly and tamely we submitted to this injustice, and now we are having further evidence in the increase of amount required to allow us to practice and use our judgment as to what drugs we shall employ. . . . The Harrison act may be the correct solution of the narcotic problem. I have positive doubts on that question; and if the profession is now going to sit quietly and allow the latest imposition to pass without protest, you can rest assured that something else will come up before long. . . .

We allowed ourselves to be imposed on to the extent of paying for the carrying out of the Harrison act. The American Medical Association, while not a political organization, should at its next meeting send a message to Congress that will not leave a doubt in the minds of that eminent body as to our feelings on the matter.

F. H. JACKSON, M.D., Houlton, Maine.

To the Editor:—Under the Harrison act we paid the required $1 license. Nine months later we are informed that Congress has increased the tax to $3 per annum and that we remit to the collector of internal revenues $1.50 for the first half of 1919. What puzzles me, and I suppose a number of other men, is what became of our tax money previously paid, and why were we not credited with the difference? It is not the amount but the principle of the thing we do not like. I suppose it is like the army game. You do what you are told and ask no questions.

ERWIN C. CARY, M.D., Reedsville, Wis.

To the Editor:—I am writing to get information that you may have in regard to the new law affecting the Harrison Narcotic Law. We have all no doubt paid our $1 which gives us a license up to July 1, 1919. Now are we to pay an extra $1.50 from Jan. 1, 1919, to July 1, 1919, or the balance due between the old and new fee?

K. E. B.

To the Editor:—Probably every practicing physician in the United States received notice to remit $1.50 to the internal revenue collector of his district to pay for a special tax stamp in accordance with the law passed in 1918 and effective Jan. 1, 1919. Every practicing physician at this time has conspicuously posted in his office a special tax stamp which attests that he has paid his fee until June 30, 1919, regardless of what new law may have been passed. Admitting that the raise in rate during the life of the 1918-1919 tax stamp is legal and nullifies the internal revenue collector's receipt, it is still odd that we are not credited with the 50 cents that undoubtedly was paid in 1918 and applies to the 1919 period from January 1 to June 30. The collector, however, overlooks this credit and asks for the entire $1.50.

In order to pay this little tax it is necessary for a great many physicians, in small towns, to secure a money order for the amount, the fee for this being 3 cents, and also to supply a stamp, another 3 cents, making 6 per cent. on the dollar paid to the government for the sending of the tax to the government.

Why not take steps toward inducing the collectors to at least furnish franked envelops to those paying the revenue tax? I respectfully suggest to physicians that each person sending a remittance for the revenue tax drop the letter containing the remittance into the postoffice without a stamp thereon. The collector will be duly notified, and he will be required to expend 3 cents to send a 3 cent stamp to obtain the remittance. A concerted action by physicians would make the revenue department take notice, and try to save the 6 cents.

B. B. S

[Comment.—The original Harrison law, approved Dec. 17, 1914, provided that "every person, partnership, association, company or corporation importing, manufacturing, producing, compounding, selling, dealing in, dispensing or giving away opium or coca leaves or any of their compounds or derivatives" must register on or before the first day of July annually and pay a special tax of $1 per annum. Under this provision, physicians as well as others were required to register and pay the tax. The registration and the tax paid in June, 1918, covered the period to July 1, 1919. The Revenue Act of 1918, approved Feb. 24, 1919, provides in addition to requiring annual registration on or before the first of July of each year that "every person who on Jan. 1, 1919, is engaged in any of the activities above enumerated (this enumeration being the same as in the original act) shall within thirty days after the passage of the act make like registration and pay the proportionate part of the tax for the period ending June 30, 1919." The act then provides for the following special tax in place of the old general tax of $1: "Importers, manufacturers, producers and compounders, $24 per annum; wholesale dealers, $12 per annum; retail dealers, $6 per annum; physicians, dentists, veterinary surgeons, and other practictioners lawfully entitled to distribute, dispense, give away, or administer any of the aforesaid drugs to patients upon whom they in the course of their professional practice are in attendance, shall pay $3 per annum." There is no provision for deduction or credit for the remaining portion of the tax paid under the old law. This would amount to 50 cents for the period from Jan. 1, 1919, to July 1, 1919. Internal revenue collectors for the various districts are now sending out notices and blanks to physicians directing them to return the registration blank with the proportionate tax of $1.50 before April 25, 1919. District internal revenue collectors are acting under instructions from the commissioner of internal revenue at Washington, and have no option regarding the amount collected or the time when it is due. Congress is responsible for the law, and the commissioner of internal revenue and the secretary of the treasury are responsible for its interpretation and administration. In regard to the suggestion of B. B. S., the district collectors would have no authority to furnish franked envelops and could not do so without instructions from the Treasury Department at Washington.—Ed.]

GREETINGS FROM ROUMANIA

To the Editor:—More than 250 English, French and Roumanian physicians, at a fraternal banquet on the occasion of the Allied victory and the delivery of Roumania by the Allied army, send to the American Society of Medicine their warm and enthusiastic homage of admiration and profound esteem. The United States of America may be proud of the medical men who have accomplished wonders of devotion and self-abnegation. On this day of triumph our thoughts go with infinite thankfulness to the United States of America, glorious and victorious protector of the right and liberty of the people.

Long Live the United States of America, forever glorious and favoring the emancipation of nations.

Asociatiunea Generala a Medicilor din Romania,
Dr. Mirinesco, President,
Dr. Jean Jiano, Secretary.

MEDICAL COLLEGE FUND NOT REDUCED

To the Editor:—A news item published in The Journal recently indicated that the appropriations for the College of Medicine of the University of Nebraska had suffered considerably at the hands of the legislature. I am pleased to report that the reductions proposed by the house committee were not permitted to stand, and a slight change in the wording of the bill gives the College of Medicine the entire amount requested by the board of regents. A total of $380,000 for the ensuing biennium is provided by the bill for the College of Medicine and University Hospital of the University of Nebraska at Omaha. Irving S. Cutter, M.D., Omaha.

Dean, University of Nebraska College of Medicine.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SPALTEHOLZ METHOD OF CLEARING SPECIMENS

To the Editor:—Please inform me where I may obtain detailed information concerning the Spalteholz method of clearing tissues.

A. Poska, M.D., Seattle.

Answer.—We quote the following from an article by Sabin in Contributions to Embryology, 3, No. 7, Carnegie Institution of Washington, 1915, which contains the chief features of Spalteholz' method, with modifications by Sabin and others:

> In general the essentials of the method are, first, fixation in formaldehyd; second, a thorough bleaching of the tissues with hydrogen peroxid to remove the hemoglobin and other pigments; third, dehydration; and, fourth, clearing the specimens in an oil which has the same index of refraction as the tissues. As applied to embryonic tissues, the method, developed by Professor Spalteholz, is as follows: The specimens, which have been injected with India ink, are fixed for from twenty-four to forty-eight hours in 5 and 10 per cent. liquor formaldehydi. Commercial formaldehyd solution is slightly acid, which is an advantage for the India ink injections, since the ink diffuses in an alkaline solution. Specimens which have been injected with silver nitrate are ruined by fixation in formaldehyd, because the silver salt is changed to a white precipitate which obscures the vessels. If injections of bone are desired, the formaldehyd solution may be made slightly alkaline and the diffusion of the ink prevented as much as possible by tying off all vessels before fixation. For large fetuses, which are to be cleared in toto, Dr. P. G. Shipley has found that the subsequent bleaching is made easier by washing the specimen in running water before fixation, thus removing much of the hemoglobin. After fixation, the specimens are washed in running tap water from twelve to twenty-four hours, followed by distilled water to remove the formaldehyd. The bleaching is done in hydrogen peroxid. Spalteholz adds a few drops of ammonia to precipitate the barium salts. This is not necessary with barium-free oxid. For adult tissues, Spalteholz uses undiluted peroxid; for the embryonic tissues about 2 to 3 per cent. is the best strength. The small embryos with ink injections take about twenty minutes to bleach; for the silver specimens, from two to three minutes suffice, and they must be watched constantly and the bleaching stopped before the silver is affected. Following the bleaching, the specimens must be washed thoroughly in running water and in distilled water. The dehydration may be begun with 50 per cent. alcohol and the percentage increased successively by five points or less. After two changes of a good grade of absolute alcohol, the specimens are passed through changes of benzene into the synthetic oil of wintergreen. The small amount of benzene which is carried over evaporates quickly, and the few bubbles which develop in the bleaching process can be removed with needles. The specimens may be made permanent in balsam.

Spalteholz' method is described by him in his book, "Ueber das Durchsichtigmachen von menschlichen und tierschen Präparaten, Ed. 2, Leipzig, S. Hirzel, 1914.

For this and additional methods of clearing tissues, reference may be made also to Guyer, M. F.: Animal Micrology, University of Chicago Press. 1917, p. 102.

NUMBER OF DEATHS AMONG PHYSICIANS IN THE UNITED STATES AND CANADA FROM 1915 TO 1919

To the Editor:—Please inform me how many physicians died and how many medical students graduated in the years 1915, 1916, 1917 and 1918. Henry S. Murray, Jr., M.D., New York City.

Answer.—The approximate number of deaths among physicians of the United States and Canada during the four years were: 1915, 2,818; 1916, 2,524; 1917, 2,645, and 1918, 3,003. During the same four years the number of medical students gratuating were: 3,854, 3,724, 3,694 and 3,077.

REJECTIONS IN THE DRAFT AND THEIR CAUSES

To the Editor:—1. Has the United States government published any statistics relating to the proportion of rejections in the late draft to those who passed successfully?

2. Has it published anything relating to the cause of these rejections?

Charles J. Foote, M.D., New Haven, Conn.

Answer.—1. According to the first and second reports of the Provost Marshal-General, the total number of registrants under the first draft was 9,586,508, of which 2,510,706 were given physical examinations, 1,779,950, or 70.89 per cent., were accepted, and 730,756, or 29.11 per cent., were rejected. In the second draft, the total number of registrants was 9,952,735, of which 3,208,446 were examined. Of these, 2,259,027, or 70.41 per cent., were accepted, and 949,419, or 29.59 per cent., were rejected. In the two drafts, therefore, 19,539,243 men were registered. Of these, 5,719,152 were examined, of whom 4,038,977, or 70.65 per cent., were accepted, and 1,680,175, or 29.35 per cent., were rejected for physical reasons.

2. No complete tabulation has as yet been published regarding the causes for rejection. Partial reports on small groups of rejections show that out of 10,000 rejections, 2,224, or 21.68 per cent., were for defective vision; 871, or 8.5 per cent., for defective teeth; 766, or 7.47 per cent., for hernia; 609, or 5.94 per cent., for defective ears; 602, or 5.87 per cent., for heart disease; 551, or 5.37 per cent., for tuberculosis; 465, or 4.53 per cent., for mental defects; 438, or 4.37 per cent., for venereal diseases; 416, or 4.06 per cent., for physical underdevelopment, and 387, or 3.77 per cent., for nervous diseases, with numerous other defects contributing from 1 to 2 per cent.

PROFLAVINE OLEATE

To the Editor:—In The Journal, March 15, 1919, p. 830, is an abstract of an article on proflavine oleate. I have the latest edition of the U. S. Dispensatory and can find nothing in reference thereto. Would you kindly give me some information about the preparation and where it can be obtained? Howard Lankester, M.D., St. Paul.

Answer.—Nothing appears to have been published with regard to the preparation of proflavine oleate except the statement that it is the oleic acid salt of the base proflavine. Proflavine is the soluble sulphate of 3,6-diaminoacridine. As far as we know, proflavine oleate is not obtainable in the United States.

Proflavine has been proposed in England for use as a wound antiseptic, based on the work chiefly of C. H. Browning and his associates, but its usefulness has been seriously questioned in the British medical journals. Recently, Browning has proposed the use of proflavine oleate; he states that it is comparatively insoluble in water; but when it, or the ointment containing it, is shaken with serum, the latter dissolves sufficient of the compound to acquire antiseptic properties. The ointment used by Berkeley and Bonney (reported in The Journal's abstract) contained 1 per cent. proflavine oleate in a base of equal parts by weight of petrolatum and calcium carbonate.

BUTTERMILK THERAPY

To the Editor:—1. Please state where I can get reliable information on buttermilk therapy. Is it possible for me to get tablets which I can add to sweet milk which will make it a good substitute for buttermilk when buttermilk is not obtainable?

2. What is it in buttermilk that makes it "agree so well" with so many people?

Please do not use my name. M.D., Wyoming.

Answer.—1. For reliable information with regard to new therapeutic measures and reliable brands of drugs proposed for them, consult New and Nonofficial Remedies. As regards sour milk therapy, this book contains a chapter which discusses the probable value of the Metchnikoff sour milk therapy. The book also describes those brands of tablets which the Council on Pharmacy and Chemistry has found to be reliable and exploited decently.

2. Probably a number of causes contribute to the fact that buttermilk is well borne in certain cases of indigestion. Among these are the beneficial effect resulting from the change of diet, and the fact that the protein of milk is partially digested in the process of souring.

CARBON TETRACHLORID AS A FIRE EXTINGUISHER

To the Editor:—I am anxious to ascertain the nature of the substance or compound used in automobile fire extinguishers (mine is a Pyrene). The fluid is highly volatile, with an odor much like carbon bisulphid; but it is not inflammable or a supporter of combustion. Possibly you know or could learn what it is composed of. I shall be pleased to send a sample if you desire.

Joseph Marple, M.D., Los Angeles.

Answer.—According to the United States Dispensatory, "Pyrene" is the trade name for carbon tetrachlorid, when sold as a fire extinguisher. The odor mentioned is probably due in part to some carbon disulphid; this impurity is present in certain commercial grades of carbon tetrachlorid.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Arkansas: Little Rock, May 13. Sec. Eclectic Bd., Dr. C. E. Laws, 803½ Garrison Ave., Ft. Smith; Sec. Regular Bd., Dr. T. J. Stout, Brinkley.

National Board of Medical Examiners: Philadelphia, June 2-7. Sec., Dr. J. S. Rodman, 1310 Medical Arts Bldg., Philadelphia.

Nevada: Carson City, May 5. Sec., Dr. S. L. Lee, Carson City.

New Mexico: Sante Fe, April 14-15. Sec., Dr. W. E. Kaser, East Las Vegas.

New York: Albany, Buffalo, New York and Syracuse, May 20-23. Mr. George M. Wiley, director, Exam. and Inspections Div., State Edu. Bldg., Albany.

New York September Examination

Mr. George M. Wiley, director, Examinations and Inspections Division, reports the written examination held at Albany, Buffalo, New York and Syracuse, Sept. 24-27, 1918. The examination covered 8 subjects and included 80 questions. An average of 75 per cent. was required to pass. Of the 91 candidates examined, 61 passed and 30 failed. The following colleges were represented:

College	Year Grad.	No. Licensed
PASSED		
Chicago Homeopathic Medical College	(1896)	1
Boston University	(1912)	1
Harvard University	(1914) (1918)	2

Book Notices

Practical Physiological Chemistry. A Book Designed for Use in Courses in Practical Physiological Chemistry in Schools of Medicine and of Science. By Philip B. Hawk, M.S., Ph.D., Professor of Physiological Chemistry and Toxicology in the Jefferson Medical College of Philadelphia. Sixth edition. Cloth. Price, $3.50 net. Pp. 661, with illustration. Philadelphia: P. Blakiston's Son & Co., 1918.

The most important feature of this book is the attention it gives to the methods of determination of different substances, particularly the more important ones, from a clinical point of view. The chapter on acidosis is of distinct value. As the volume deals primarily with physiologic chemistry, the space devoted to the description and enumeration of blood corpuscles or to the description of the morphologic elements of pathologic urine might better be devoted to matters more germane to the subject. If it is the intention of the author to include the excretion of drugs, the chapters on arsenic and mercury are not sufficient; if not, they are out of place. The illustration of the Berthelot-Atwater calorimeter, which could be clearer, should be supplemented by a description of its use or be left out entirely. The space given to the subjects mentioned might be devoted to some such purpose as the methods of quantitative determination of lactic acid. *d*-ribose deserves to be mentioned by name at least. On page 64 it is stated that "the nitrogen in the protein molecule occurs in at least four different forms as follows: I Monamino acid nitrogen, II Diamino acid nitrogen or basic nitrogen, III Amide nitrogen, IV A guanidine residue." No doubt the amid under III is a misprint and should read imid. But the statement is confusing. The nitrogen in I and II occurs in the same form. What is meant is that the protein molecule is made up of various nitrogen-containing components, which may be classified in the manner indicated: I, monamino acids; II, diamino acids; III, substances containing nitrogen in imid form, and IV, substances containing nitrogen as in guanidin. These remarks are not intended to detract from the value of the book as a practical physiologic chemistry; as such it serves a useful purpose in an admirable manner.

Estudio Clínico de la Litiasis Urinaria: Casuística. Cálculos del Riñón, del Uréter, de la Vejiga y de la Uretra. Por el Doctor Angel Pulido Martin, Cirujano del Hospital de San Juan de Dios. Paper. Pp. 238, with illustrations. Madrid: Imprenta del Sucesor de Enrique Teodoro, 1918.

Pulido here reviews the clinical histories of the varied cases of stones of the urinary system, of which he has long made a specialty. He admits at the outset that we still have much to learn in regard to the causes that underlie the formation of calculi, passing then to enumerate the different explanations that have been advanced so far for this condition. The author discusses the various types of calculi, considering in detail symptomatology, diagnosis and treatment. In the chapter on diagnosis, he takes up in succession and at some length the assistance that may be derived from palpation, various types of sounds and explorers, the Bigelow aspirator, the cystoscope, the roentgen rays, the application of anesthesia, and the diagnostic value of the location and character of the pains that may be present.

A Handbook of Colloid-Chemistry: The Recognition of Colloids, the Theory of Colloids, and Their General Physico-Chemical Properties. By Dr. Wolfgang Ostwald, Privatdozent in the University of Leipzig. Second English Edition. Translated from the Third German Edition by Dr. Martin H. Fischer, Professor of Physiology in the University of Cincinnati; with Numerous Notes Added by Emil Hatschek, Cass Institute. Cloth. Price, $3.50 net. Pp. 284, with 63 illustrations. Philadelphia: P. Blakiston's Son & Co., 1919.

The original translation has been revised and brought up to date by the translators. Colloid chemistry as a separate field of investigation is a relatively recent offspring of physical chemistry. Not many books are in existence which attempt to treat the subject comprehensively. The "practical introduction" gives an elementary general and special colloid analysis, that is, the elementary means of recognizing matter in colloidal state from matter not in colloidal state, and the manner of differentiating between various colloidal systems. Part I treats of general colloid chemistry. Paragraph 17 is captioned "The Concept of Colloid-Chemistry," and defines its field thus: "Colloid-Chemistry deals with the relations of the surface energies to other kinds of energy as shown in an especially characteristic way in dispersed heterogeneous systems." Part II treats of the mechanical properties of colloid systems. The book is apparently not intended as an easy introduction for the beginner in colloidal chemistry. It cannot fail to impress the reader with the far-reaching importance of the study of matter in the colloidal state.

War Story of the Canadian Army Medical Corps. By J. George Adami, M.D., F.R.S., A.D.M.S., in Charge of Records, Office of Director General Medical Services, O. M. F. C. Volume 1. Published for the Canadian War Records Office. Cloth. Price 5 shillings net. Pp. 288, with illustrations. London: Colour Ltd., 1918.

Dr. Adami needs no introduction to the medical profession as a writer either on scientific or on literary subjects. He wields a trenchant pen and guides it with a carefully accurate, far-seeing mind. In this instance, he approaches his subject with deep personal sympathy and feeling; the Canadian Army Medical Corps is fortunate in its present historian. This first volume concerns the rise of the C. A. M. C., its assembly, the second battle of Ypres, with the introduction of poison gas, and the establishment of hospital units in France, and other medical units on the line of communication. The next volume is to take up the work of the sanitary section of the first Canadian division, and continue the history of the Canadian Army Medical Corps during 1916. The story is enlivened by many personal notes from the diaries of officers intimately connected with the work. Numerous well drawn maps make clear the descriptions of action in the field. All who took even a remote part in the great conflict will find this a most interesting work.

Medicolegal

Standards for Treatment with Roentgen Rays

(Hunter v. Burroughs (Va.), 96 S. E. R. 360)

The Supreme Court of Appeals of Virginia, in a lengthy opinion, affirms a judgment in favor of plaintiff Burroughs for damages alleged to have been occasioned to him by the alleged malpractice of the defendant, a physician, in the treatment with roentgen rays of eczema with which the legs and ankles of the plaintiff were affected. The court says that it should be borne in mind that the case involved two standards of professional skill and care by which the evidence as to the competency and the conduct of the defendant was to be measured: one standard having reference to the technic or mechanical operation of the roentgen-ray apparatus, and the other standard having reference to the possession and use of the professional skill and care incumbent on the defendant with respect to the diagnosis and treatment of the disease of the plaintiff in matters other than the mere mechanical operation of the apparatus.

The two standards mentioned both involved, in this case, the highly specialized art of the treatment of the disease of the plaintiff by roentgen rays; and, so far as they did so, expert testimony before the jury fixing such standards was essential to the support of the verdict of the jury, since otherwise the jury, to the extent of the questions involving such specialized art, would have had no standard in mind by which to measure the other facts proved in the case. Now, as to the mechanical standard of skill and care, there was no expert evidence in the case except the testimony of the defendant and of other expert witnesses for the defendant; but there was sufficient evidence in the case, when measured by the mechanical standard fixed by the testimony of the defendant, to support the verdict of the jury. It is deemed sufficient to mention only the following details of such evidence: There was evidence in the case to the effect that the defendant did not keep an accurate record of the roentgen-ray treatment or any record of the exact "dose" of roentgen rays applied in the several treatments therewith; that if only the standard "dose" had been applied, it was extremely improbable that any bad result would have been caused. The cross-examination of the defendant tended to show that his memory of the "dose" applied by him in the several treatments was not to be relied on. There were inconsistent statements made by the defendant at different times as to his opinion of the causes of the bad result; and there was other evidence to support a conclusion of the jury that the "dose" in fact applied was not in accordance with the mechanical standard fixed by the expert testimony of the defendant himself. It was true that such testimony did not show that the bad result might not have happened without fault of the defendant; but there was sufficient of such evidence, the credibility and weight of which was for the jury, tending to show that the bad result was more probably due to lack of skill or negligence of the defendant as charged. This degree of proof is all that is required of a plaintiff in a civil case. He is not required to exclude by his proof the possibility of the result complained of having been due to causes for which the defendant is not responsible.

The cause of the injury being the roentgen rays was, however, but one element of fact in the case. As the jury was properly instructed, if the defendant exercised ordinary care and skill in the premises, the plaintiff was not entitled to recover damages, although the injuries complained of were caused by the roentgen-ray treatment; and the question still remained whether the defendant did or did not exercise such care and skill. The court thinks there was sufficient evidence in the case, when measured by the general professional standard, as well as by the mechanical standard of skill and care, to support the verdict of the jury.

It was correct to say that the standard by which the duty of the defendant to make the preliminary tests and examination of the patient before subjecting him to the roentgen-ray treatment had to be tested was whether other like specialists in good standing, in the same or similar localities as the defendant, would have been guilty of the omission to make such preliminary tests and examination, which test had to be applied by measuring the evidence, as it might be introduced on the trial, by the standard fixed by the testimony of experts on the subject. Failure to warn of danger in the treatment was not necessarily negligence, unless there was an assurance of a cure.

Waiver of Privilege by Implied Consent

(Dahlquist v. Denver & R. G. R. Co. (Utah), 174 Pac. R. 833)

The Supreme Court of Utah reverses a judgment obtained by the plaintiff, with direction to grant a new trial, in this personal injury case, on account of the erroneous exclusion of the testimony of a physician as privileged. On his direct examination, the plaintiff himself had testified somewhat in detail concerning the character and extent of his injuries, the pain and suffering endured, and his physical condition before and after the accident. He had also testified concerning the mode of treatment of his injuries and their character as described to him by the physician whose competency to testify was challenged by the plaintiff under the provisions of the Utah statute that:

> A physician or surgeon cannot, without the consent of his patient, be examined in a civil action, as to any information acquired in attending the patient which was necessary to enable him to prescribe or act for the patient.

The court says, on an application for rehearing which it denies, that a majority of the court agreed that where a party voluntarily, in a trial of his own cause, states what his physician did and said respecting the injuries which are the subject of litigation, he should not be permitted to close the mouth of the physician when offered as a witness by his adversary solely on the ground of privilege. That was the question here involved, and the only question intended to be determined. It was not intended to hold that the waiver of privilege opens the door for immaterial or irrelevant questions. The question as to whether or not the plaintiff was afflicted with syphilis was wholly immaterial in this particular case. The plaintiff was in the employment of the defendant as an able-bodied man at the regular wages usual in such employment. This was substantially admitted in the pleadings. If he was injured by the negligence of the defendant, and his permanent recovery rendered more precarious and doubtful by reason of such disease, the court knows of no authority or legal principle under which the defendant could claim immunity either wholly or in part on that account. The questions were therefore immaterial and were objectionable on that ground, but not on the ground of privilege.

It was contended that there is a vital distinction between the terms "waiver" and "consent" in the statutes pertaining to privilege; that where the word "consent" is used it means express consent, and not consent by implication. But counsel did not furnish the court with any authority on the subject supporting such distinction, nor has the court been able to find any. On the contrary, it appeared from their own argument that some statutes relating to privilege render a witness incompetent to testify in such cases and make no provision whatever for a surrender of the privilege either by waiver or consent. Notwithstanding this, the courts in those jurisdictions recognize the doctrine of waiver and find it by implication from the conduct of the party. Certainly, if waiver or consent may be implied under statutes which do not expressly provide for either, it ought not to be considered revolutionary to deduce it from a statute like that of Utah which expressly provides for it. The court is of the opinion that an examination of the several statutes of other states, and the decisions of the courts construing them, will disclose no warrant whatever for the distinction relied on by the defendant.

It was contended that statutes pertaining to privilege should be strictly construed. The court believes the statute should receive a reasonable construction. It does not believe that a statute which excludes testimony calculated to disclose the truth in the trial of a case should receive a rigidly strict construction in favor of the exclusion unless the terms of the statute are such as to leave no doubt that such was the intention of the lawmaking body. The statute of Utah provides that the privilege may be surrendered by consent, and the court is of the opinion that the consent may be implied from the patient's conduct.

The court believes that when a patient, who afterward becomes a party in court, is sworn as a witness in his own behalf and details the treatment applied by his physician, and states what his physician said concerning the injury or disease and its probable effects and consequences, he thereby consents to the physician testifying to the same extent that any other witness might testify if sworn in the case. And the court is convinced that its position is sustained by the great weight of authority.

*Function of Nucleus of Living Cell. V. Lynch, Baltimore.—p. 258.

Specific Dynamic Action of Protein.—Evidence is presented by Burge to show that the amino (NH_2) group in the protein molecule renders protein, or meat, a more effective stimulant to catalase production and hence to heat production than fat, and that the glycerin radical in the fat molecule renders fat more effective in this respect than sugar.

Effect of Gland Extracts on Bile Secretion.—Downs and Eddy found that the amount of bile secreted is increased by secretin, and decreased by epinephrin and by mammary, orchic, ovarian, pancreatic and thymic gland substances. The bile secretion is not affected in a constant or definite manner by the substance of the spleen and thyroid.

Bakers' Yeast as Food for Man.—The metabolism of six men was studied by Hawk and others. Four of the six showed an improved nitrogen balance when fed the yeast diet. Moreover, the yeast diet produced an average daily gain of about 0.4 gm. of nitrogen per man above that noted before yeast was fed. The only interpretation is that these men found yeast a satisfactory article of diet. The yeast may be incorporated with meats, such as hamburg steak, and yields a preparation of very satisfactory taste. If the yeast is dried in a current of air at 105 C. and pulverized it may be substituted for 20 per cent. of the wheat flour used in bread making and yields a product which is very nutritious and of an attractive flavor. The average individual may ingest yeast sufficient to yield from 1 to 2 gm. of nitrogen per day, without securing any laxative effect. When as high as 4 gm. of yeast nitrogen are eaten, a laxative effect is generally observed and in some cases soft diarrheal stools result. It is suggested that this laxative action of yeast may be put to good use in overcoming constipation.

Compressed Yeast as Food for Growing Organism.—The results of these experiments made on rats show that the ordinary household compressed yeast has very important growth-promoting properties.

Function of Nucleus of Living Cell.—The experiments reported by Lynch offer support to the theory that the nucleus is the organ of synthesis. The enucleated cell may move, respire, digest, respond to stimuli and exhibit any activity which is dependent solely on catabolic or destructive processes of protoplasm. The group of phenomena which it never shows are those of growth and of regeneration and division. The phenomena of growth are essentially phenomena of organic synthesis, and the dependence of growth on the nucleus implies the dependence of organic synthesis on the nucleus.

Influenza Epidemic in Tuberculosis Hospital.—The influenza bacillus was found by Corper and Downing in the nose and throat of a fairly large percentage (14 per cent.) of apparently normal individuals, without symptoms of influenza, at the United States General Hospital No. 16, during the 1918 influenza pandemic. The organism was, however, isolated from a larger percentage (28.5 per cent.) of patients presenting symptoms of influenza. The influenza bacillus was isolated from the nose and throat of 24 per cent. of consumptives who were free from symptoms of acute disease, while in those presenting such symptoms the bacillus was obtained in 62 per cent. of the cases. In cases of typical uncomplicated influenza, the influenza bacillus was obtained in the sputum from 75 per cent. of the cases, while in patients presenting a bronchopneumonia, the organism was obtained in 100 per cent. of the cases. The influenza bacillus was not the only organism obtained from the sputum of influenza patients, but was commonly accompanied by some other organism, most frequently the pneumococcus (Type I, II, III or IV) or streptococcus. The latter organisms did not, however, occur as consistently as the influenza bacillus. Blood cultures in cases of influenza were uniformly negative for the influenza bacillus. Necropsy findings on eleven cases of influenza bronchopneumonia (seven of which presented pulmonary tuberculosis in some form; four active and three healed cases) revealed the influenza bacillus in the lungs in ten cases and the pneumococcus in eight. Influenza bacilli were never found in the blood, but pneumococci were found in three of the seven cases examined. The presence of the influenza bacillus in the sputum, during influenza epidemics, seems to be of definite diagnostic value, especially when taken in conjunction with clinical and roentgenologic findings.

Tuberculin in Treatment of Pulmonary Tuberculosis.—All things considered, this study by Waters and Peters does not furnish very impressive evidence of the value of tuberculin as a therapeutic agent in pulmonary tuberculosis. Its influence, if any, was in all probability extremely limited.

*Renal Function Influenced by Proteose Intoxication. I. McQuarrie and G. H. Whipple, San Francisco.—p. 421.

Cultivation of Meningococcus.—The experiments reported by Gates are the outcome of observations made in applying the recommendation of Cohen and his associates that meningococci be grown at a partial oxygen tension, obtained by substituting carbon dioxid for approximately 10 per cent. of the air in a closed container. Gates found that the meningococcus is not a "micro-aerophil." It grows equally well in atmospheres containing from 15 to 40 per cent. oxygen. If small amounts of carbon dioxid affect the growth of the meningococcus on an artificial medium it is by changing the reaction of the medium, not by slightly reducing the oxygen tension of the surrounding air. The fallibility of titrating the total acidity of a medium is again clearly demonstrated. A reaction favorable to the meningococcus cannot be determined from the total titratable acidity, but depends solely on the hydrogen *ion concentration of the medium.* The optimum for the meningococcus is approximately at p_H 7.4. The value of a moist chamber in the cultivation of the meningococcus is shown by unusually luxuriant growth when other conditions are also favorable.

Wassermann Reaction.—The question of the Wassermann reaction as practically applied was reviewed by Lewis and Newcomer with the purposes of (1) reconsidering the suitability of the cholesterolized antigen, and (2) examining the merits of the newer Noguchi system. They found that the Wassermann reaction carried out according to the method of McIntosh and Fildes, with cholesterolized antigen and with certain allowances for the presence of native antisheep amboceptor, leads to about the same result as when it is done according to the recent proposal of Noguchi, with the native human complement and acetone-insoluble lipoids as antigen. The differences are such as to suggest that from the point of view of diagnosis the Noguchi method is the more conservative but that there is definite advantage in using two methods as distinct in origin of materials as these, partly for the purpose of control and partly in hope of acquiring new information of importance. As a measure of control of treatment, the cholesterol antigen appears to the authors to be the more valuable. The Wassermann reaction alone, by whatever method it may be done, can only be used in the diagnosis of syphilis in conjunction with presumption based on other grounds. That it fails to appear in a considerable percentage of syphilitics is well known. That the reaction is positive in other conditions is not so generally recognized. Fresh instances of this in certain febrile cases are here recorded.

Estivo-Autumnal Malarial Infections.—The anemia in malarial infections, in Lawson's opinion, is explained by the fact that each parasite destroys several red corpuscles. Reduction of hemoglobin out of proportion to the loss of red corpuscles is explained by the fact that there is always a partial loss of hemoglobin in certain of the surviving corpuscles due to parasitic action. Migration of parasites occurs in all estivo-autumnal infections.

Newly Formed Connective Tissue.—The tensile strength of newly formed connective tissue was thus evaluated by Lewis and Newcomer: Adult rabbits were anesthetized with ether. With various degrees of aseptic precaution the Achilles tendon was exposed and sectioned. At various intervals thereafter the animal was killed and the leg amputated at the hip and suspended by the knee through a strong wire loop as an intermediary to a stout chain hung from the ceiling. With a similar wire loop a pail was suspended from the hock. Into this pail clean sand was run from a funnel at a uniform rate and from a uniform height. When a break occurred the flow of sand was stopped, the pail, its contained sand, and all the apparatus coming away with the foot were weighed, the result being recorded in grams as the tensile strength of the newly formed tissue.

Virus of Poliomyelitis in Nasopharynx.—The results of the experiments reported by Flexner and Amoss conform closely with clinical experience in the United States, at least, and especially with the observations made by epidemiologists in the course of the wide epidemic in New York state and elsewhere during the summer and autumn of 1916. The conclusion reached at that time was to the effect that the communicability of the disease was a phenomenon chiefly of the early stages, while the frankly paralyzed person and the convalescent were to be feared much less. In the authors' experiments, infection was secured with tissues obtained during the first week, approximately, of the disease but not at the later periods. The deduction from the experiments reported is to the effect that the virus is regularly present in the nasopharynx in cases of poliomyelitis in the first days of illness, and especially in fatal cases; that it diminishes relatively quickly as the disease progresses, except in rare instances; and that it is unusual for a carrier state to be developed. Hence the period of greatest infectivity of patients would appear to be early in the disease, which is probably the time at which communication of the virus from person to person takes place. Available evidence proves that healthy carriers of the virus occur. The authors do not, however, possess data which indicate the frequency with which carriage arises. The fact that even after a severe and wide epidemic, such as occurred in the United States in 1916, the disease may virtually disappear within two or three years, points to the probability that enduring carriers of the active virus, whether healthy or chronic, are of exceptional occurrence.

Renal Function in Intestinal Obstruction.—The eliminative function of the kidneys during periods of intoxication due to intestinal obstruction was investigated by McQuarrie and Whipple. Associated with the intoxication of intestinal obstruction there exists a definite impairment of the excretory function of the kidneys. The degree of functional depression corresponds roughly with the intensity of the clinical intoxication. The decrease in the uria ratio and in the capacity of the kidneys to excrete sodium chlorid is more marked than is the percentage decease of phenolsulphonephthalein elimination. The great increase in the nonprotein nitrogen of the blood usually observed in acute intestinal obstruction, which has hitherto been explained as being due entirely to an increased rate of protein catabolism, is due in part to retention of the products released from the injured cell protein. The authors suggest that it is probable that the impaired renal function is due to direct action of the toxic substances on the renal epithelium. The actual demonstration of this renal injury is perhaps the strongest evidence so far obtained to prove the presence of an actual toxic substance in the blood during intestinal obstruction. This obscure disability of the kidneys during the height of the intoxication of acute ileus should always be considered in the clinical management of this condition. It may also serve as a guide to indicate the degree of intoxication.

Renal Function in Proteose Intoxication.—The outstanding fact presented by McQuarrie and Whipple is that the injection of the toxic proteose obtained from the contents of the obstructed small intestine causes a definite impairment of the eliminative function of the kidneys as shown by a decreased capacity to excrete urea, sodium chlorid, and phenolsulphonephthalein. This involvement of the renal function is similar to that shown by the preceding report to accompany the intoxication of intestinal obstruction. The observed depression of function is readily demonstrable even when large amounts of fluid and urea, dye, or salt are injected directly into the blood stream. There is in all probability a temporary injury of the kidney cells, since the most important extrarenal factors have been largely eliminated in the experiments. There is no appreciable impairment of the renal function following the injection of a number of other proteose preparations from a variety of sources. This study affords new evidence in favor of the view that the function of an organ can be profoundly disturbed for a time without any demonstrable anatomic lesions. The repair of this type of injury promptly follows the disappearance of the intoxication, and is functionally and anatomically perfect.

Bacteriologic Analysis of Milk.—One hundred and thirty-six milks, varying in bacterial content from 50 to 160,000,000 per cubic centimeter, have been analyzed by Simmons by five different methods: direct microscopic, standard plate, lactose plate, little plate (Frost), and reduction test. In milks containing less than 1,000,000 bacteria per cubic centimeter, the three methods—standard plate, lactose plate and little plate—gave closely comparable results. The lactose plates on the whole gave results slightly higher than the plain agar plates, and these results seemed to follow the trend of the little plate counts somewhat more closely than the standard plates. The direct microscopic count was less reliable with milks having a low bacterial content than it was with poor milks. In milks containing upward of 1,000,000 bacteria per cubic centimeter, the lactose plates were found to be considerably higher (50 per cent.) than the standard plates, the little plates tended to run somewhat lower, while the direct microscopic count gave highly satisfactory results. The time of the reduction test varied from one-half hour to thirty hours. Occasionally inexplicable variations occurred in the different classes of milks, but when these were smoothed out by applying a "moving average," a curve was obtained which closely approximates those obtained by the other methods.

Specificity and Formation of Proteolytic Enzymes.—The work done by Diehl suggests that differences in the chemical constituents of mediums may account for many of the unverified "new strains" of bacteria, the differentiation of which is based on some minor phase of their action on culture mediums. For instance, on a medium containing no organic nitrogen, no proteolytic enzymes are formed by bacteria. On gelatin, casein, broth, agar and peptone, enzymes are formed which will digest both gelatin and casein. Proteolytic enzymes are apparently formed to correspond to the different amino-acids present in the medium and will then attack these acids whether combined or free. These enzymes are not preformed in the bacterial cell but are dependent on the content of the medium on which it grows.

Rat-Bite Fever Spirochete.—In the infected wild rat, white rat and guinea-pig, the spirochete of rat-bite fever, in the early stages of the infection, was detected by Kusama and others principally in the blood; but after two weeks a large number appeared in the connective tissues, and as time went on this number was gradually increased. That is, this spirochete was always distributed numerously in the subcutaneous and submucous tissues of the eyelids, lips, bridge of the nose and tongue, and was especially abundant in the reticular connective tissue of the vascular sinus surrounding the follicle of the tactile hair of the upper eyelids and lips. It was also usually, if not always, found abundantly in the capsules of the salivary and lymph glands, in the heart wall, in the adventitia of the aorta and large arteries within the visceral organs, and sometimes in the endocardium of the heart. It could also be detected in the spleen, the liver, the suprarenal glands, the kidneys, the parenchyma of the salivary and lymph glands, etc. The spirochete was neither excreted through the saliva from the salivary gland nor mixed into the saliva through the normal mucous membrane of the mouth cavity from its submucous source. The excretion of the organism in the urine was comparatively rare. It is transmitted to a healthy animal through a wound caused by the bite of an infected animal, and the authors believe that in order to be transmitted it passes from the submucous source or from the circulating blood through an abrasion in the mouth, such as frequently occurs in the wild rat at the time of the bite. By keeping the infected and healthy animals in the same cage, they found no positive case among eleven guinea-pigs, and only two positive cases among twenty-nine mice. By feeding experiments they could find only two positive cases among fourteen guinea-pigs, and four among twenty-nine mice, so that it is natural to suppose that the infection in the positive cases resulted from an injured surface in the alimentary canal rather than by transmission through the normal mucous membrane. By instillation of the infected blood into the eye, they proved only one positive case among nineteen mice, and four among fourteen guinea-pigs. Thus, it seems hardly possible that this organism enters the animal body through the normal conjunctiva, at least, in the case of the mouse. The monkey inoculated with human or wild rat strain shows the pyrexia of relapsing type, but if the field vole strain is used, there is no fever.

The immune serum of the Japonese monkey treated with the human or wild rat strain exerts a spirocheticidal action on all three strains, while the field vole serum has only a slight action on the field vole strain, but none on the other two. The Japanese monkey, recovered from the infection, even if it be caused by the field vole strain, does not show any further symptoms after being reinoculated with human strain. The spirochete under discussion does not undergo any considerable variation in virulence and immunizing power, in passing through the body of the human being, monkey, guinea-pig, wild rat, white rate, mouse, etc., but in passing through the body of the field vole it seems to decrease its toxophore and haptophore groups quantitatively.

Exclusion of Air in Cultivation of Gonococcus.—Cultures of gram-negative diplococci have been obtained by Ruediger from gonorrheal material on medium composed of veal broth, made neutral to phenolphthalein, agar, salt, peptone and 10 per cent. human blood which had been heated to 56 C. for thirty minutes. Little or no growth was obtained on medium containing unheated human blood. On medium without salt, the diplococci grew about as well as on the medium with salt. The addition of glycerol or glucose seemed to be unfavorable as was also the omission of peptone. The culture tubes had to be stoppered air-tight. The growth obtained was nearly as luxuriant as that of *B. typhosus* on ordinary nutrient agar, and so far has been uniformly successful.

Germicidal Power of Oils and Oil-Dissolved Substances.—The typhoid bacillus was used by McMaster in his work. About twenty tubes of each type were planted on nutrient agar, and after from twenty-four to forty-eight hours' growth the tubes were filled with liquid petrolatum containing various percentages of phenol. Of the forty-eight-hour cultures, none were killed by 0.2 per cent., but all were killed by 0.6 per cent. phenol. In about half of the tubes 0.4 per cent. killed. The most resistant cultures were those in which the surface had been intentionally wounded, the growth being therefore rather deep and presumably protected from the action of the disinfectant. The minimal killing concentration of paracresol was from 0.2 to 0.3 per cent. and of guaiacol from 0.8 to 1 per cent. The particular brand of oil used did not change the results in any way. The action of phenol in all oils is the same. Experiments with menthol, camphor and turpentine resin showed that these did not kill in the highest concentrations that could be obtained. A series of tests were also made of dichloramin-T, eucalyptol, chlorinated liquid petrolatum and chlorinated eucalyptol. McMaster believes that his method may provisionally be regarded as satisfactory for determining quantitatively the germicidal power of antiseptic oils and substances dissolved in oil.

Hemolytic Streptococci in Tonsils as Secondary Invaders.—Hemolytic streptococci were recovered by Pilot and Davis by swab cultures in sparse numbers from the pharynx and tonsillar surfaces in 61 per cent. of 100 throats, chiefly children with hyperplastic tonsils; and from the crypts of the excised tonsils of the same individuals in 97 per cent., usually in predominating numbers. Swab cultures are, therefore, unreliable in determining the incidence of this organism in the respiratory tract. The frequency of hemolytic streptococci is decidedly less in the throats of persons whose tonsils have been extirpated than in the throats of persons with normal tonsils. The authors suggest that hemolytic streptococci from the crypts of tonsils are probably the most important source of the streptococcus complications of the various acute infectious diseases, and of the terminal infections.

Double Sugar Medium.—The double sugar medium used by Kendall and Ryan contains saccharose, 1 per cent., and mannitol, 0.1 per cent. It distinguishes between the various saccharose acid and gas, and the mannitol acid and gas producers, thus materially increasing the definiteness of cultural diagnosis and reducing somewhat the necessity for final agglutination with specific or polyvalent serum.

Prepuce as Grafting Material.—A case is cited by Eisenberg in which the patient, a boy, 16 years of age, lost the last phalanx, part of the periosteum of the second phalanx, and the skin down to the lower third of the first phalanx of one of his fingers. A plastic operation was done, using the prepuce for grafts. On the thirty-eighth day after the accident, Eisenberg performed circumcision; then, after having the prepuce emptied of blood, he made a few buttonholes to allow free escape of serum and underlying air, pressed the graft firmly in place, all in one piece (like a finger stall), in order to remove the blood, bulbs of air, and as much moisture as possible. It was then dressed with neutral solution of chlorinated soda, a cotton wool bandage being applied firmly to insure close adaptation of the graft to the granular surface of the finger. In sixty days, cicatrization was complete.

Prevention of Influenza.—This report details the measures in use during the recent epidemic. Nothing new is added.

*New Technic for Suspension of Kidney. R. M. Penick, Shreveport, La.—p. 444.

New Technic for Suspension of Kidney.—Penick uses the Kelly incision, approaching the kidney through the superior lumbar trigonum, only he makes the incision a little larger, if necessary. When the deep lumbar fascia is reached it is opened with a clean cut, and beginning at the lower angle of the wound a ribbon of fascia is dissected about two-thirds inch wide. The end is secured with a hemostat and laid aside for the present, and the operator proceeds to deliver the kidney up into the wound as usual. The perirenal fat is stripped to the hilum and the capsule incised and dissected, the sutures introduced, two on each side. These sutures are caught in hemostats and laid aside while the perirenal fat is gathered by a circumferential large suture, forming a cup-shaped support under the kidney, and the ends are left long for later attachment at the lower angle of the wound in the musculature. The ribbon of fascia is now picked up and a large chromic gut suture threaded into the end to prolong it; it is then fitted around the lower pole of the kidney, just below the hilum, and a stitch securing it to the capsule of the kidney near the front is introduced to prevent slipping. The ends of the suture, prolonging the ribbon of the fascia, are left in the hemostat while the kidney is being replaced, and the sutures of the capsule are secured in the adjacent musculature, as usual in this procedure. When this stage is reached the kidney is placed in the position desired and the suture prolonging the ribbon of fascia threaded on a carrier or large needle and fixed in the muscles of the back, at the most convenient point, fitting snugly around the kidney and holding it securely while the denuded surface on the kidney forms adhesions. The large sutures in the subphrenic fat securing a support under the kidney are now drawn sufficiently taut, forming a cup-shaped support. This last procedure closes the loose space under the kidney. The wound is then closed in the usual way, layer by layer.

Pneumothorax in Tuberculosis.—For the past six years, Peters has been treating suitable cases of tuberculosis by means of compression and with good results. He has seen apparently hopeless cases cured, and has seen the last days of the dying consumptive made easier by a relief of distressing symptoms. Peters gives facts based on a large experience, and a careful study of the literature, with the hope that more physicians will be induced to use a real means of aiding the tuberculous patients. The next paper will give details of the observations made by Peters.

Bacteriology of Pneumonia.—One hundred and twenty-four cases that came to necropsy and from which cultures were obtained are analyzed, as to their bacterial findings, by Birge and Havens. Of these, sixty cases were typed antemortem. In a strikingly large number of cases, *Streptococcus hemolyticus* was the predominating organism, and relatively a large number of cases in which it was the predominating organism antemortem. The relatively large number of Type III pneumococci recovered at necropsy coupled with the relatively small number found antemortem is accounted for by the fact that a large number of specimens of sputum were poor when submitted for examination. The numbers of Type III pneumonias, confirmed by necropsy, was practically the same as the numbers of Type IV. A search was made for healthy carriers of Type III pneumococci in an attempt to explain the cases found. Among the 600 men examined, 2 per cent. were found to harbor this type. These men gave no history of their association with pneumonia, and were possibly the source of the cases entering the hospital. The cases which showed *Streptococcus hemolyticus* both antemortem and postmortem occurred early in the epidemic, when there were a large number of healthy carriers of this organism in the camp and most of the admissions to the hospital showed a pedominance of this organism in the throat cultures. It is considered, in these cases at least, as being the cause of the infection and death. *Bacillus influenzae* was isolated from only one case during the epidemic in which this organism might possibly be considered as the etiologic factor. *Bacillus influenzae* was isolated both from the sputum and at necropsy in eleven other cases, but only in connection with other organisms which were more virulent and which could account for the pathologic changes found at necropsy. Of the twenty-eight cases of Type IV pneumococcus found in the sputum antemortem only nine were confirmed by the necropsy findings.

Endemic Malaria as Military Problem.—Haughwout calls attention to the fact that the recruiting of large bodies of men destined to form army units, from areas in tropical countries where malaria is known to be endemic, is certain to bring together many men, who, apparently healthy, are yet carriers of the malarial parasite and are capable of conveying it to healthy persons. These carriers, in the presence of anopheline mosquitoes, are a source of peril to any community that is comparatively free from the malarial fevers. They are likewise a peril in their own garrison, and great care should be exercised in the selection of a site on which to establish a training camp. Such men, on undergoing the heavy work of military training, with its attendant fatigue and exposure, are extremely likely to develop the disease in its active form with the consequence that the effective strength of their unit will be reduced.

Streptococcus Infections of Lungs.—During the investigation of a severe epidemic of diarrheal diseases, a group of cases was encountered by Wilson which presented relatively unusual features: first, in that the degree of anemia was quite out of proportion to the amount of blood present in the first few days in the feces, and second, in that the patient frequently developed the physical signs of pneumonia, a pneumonia which ran a prolonged course, was accompanied by citron-colored sputum, and terminated by lysis. The examination of the feces microscopically and culturally brought out the fact that in all the cases there were very large numbers of streptococci, and that in those cases passing almost pure blood they were present in a great state of purity. The sputum of twenty-three cases of secondary pneumonia was examined. The microscopic appearances were uniform. In the early stages the cellular elements were few, but by the third day of the pneumonic symptoms there was a large increase consisting mainly of polymorphonuclear and endothelial cells. The organisms were mainly of the streptococcal type; sometimes they were present in practically pure culture. Blood cultures also were made in twenty out of the twenty-three cases; streptococci were obtained from the blood culture. It could, as a rule, be recovered up till the sixth day of the illness. All the patients gave a history of having drunk shell-hole water, the diarrheal symptoms ensuing from one to five hours later. In an inquiry into the bacteriologic flora of such waters it was found that in twenty-eight out of forty-two specimens examined, streptococci were present in large numbers.

Susceptibility of Convalescents from Measles.—Of the 388 cases of measles analyzed by Levy, 119 had complications, a number of patients suffering from more than one. The complications of measles occurred almost exclusively among streptococcus carriers, the incidence in this group being 36.8 per cent. as contrasted with 6.4 per cent. in "clean" cases. Furthermore, the four complications noted among the noncarriers were of distinctly minor nature—two instances of acute bronchitis, one acute tonsillitis, and one cervical adenitis. Bronchopneumonia occurred forty-seven times, or in 12.1 per cent. of all cases. Fifteen, or 34 per cent., of the bronchopneumonias developed empyema. On culture, thirteen pleural fluids showed *S. hemolyticus*, one pneumococcus. From eleven specimens of pus obtained from cases of acute otitis media, *S. hemolyticus* was grown 9 times; *Staphylococcus aureus* twice. Of 326 carriers, either entering the hospital as such, or becoming infected after admission, 211, or 63.2 per cent., had no complications.

*Spread and Incidence of Intestinal Protozoal Infections in Population of Great Britain. J. R. Matthews and A. M. Smith.—pp. 349 and 361.

Quinin in Malaria.—The authors experimented with the administration of 30 and 90 grains of quinin per week, given in equal doses daily for six days and in two doses, one on each of two consecutive days. They found that, given a total weekly dose of quinin, it is better as a palliative to divide it into two equal parts and administer one on each of two consecutive days, than to divide it into six equal parts and administer one on each of six consecutive days; in other words, as a palliative, interrupted is preferable to continuous quinin treatment in simple tertian malaria.

Intramuscular Injections of Collosol Manganese in Malaria.—This preparation was tried in fifteen cases. The drug was injected intramuscularly, 1 c.c. on each of two consecutive days in fourteen cases and 1 c.c. on each of three consecutive days in one case. The drug was of no value.

Arsenic in Malaria.—The authors have found that the daily administration of arsenic, or of arsenic and strychnin, in small doses (15 minims) in combination with quinin (5 grains) is not more effective than the same dose of quinin alone. As a palliative, liquor arsenicalis (B. P.) 30 minims daily, appeared to exert a definite control of the temperature, the average weekly number of cases in which there were parasitic febrile relapses being only 3.8 per cent. of cases treated; on the contrary, however, it failed in many cases to keep the cutaneous blood free from parasites, the average weekly number of cases in which there were parasitic relapses (febrile and nonfebrile) being 28.1 per cent. of cases treated. As a curative, the treatment was practically valueless, being followed by 85 per cent. of relapses. The same treatment, however, with two initial injections of quinin dihydrochlorid, 15 grains, gave very different results. The average weekly number of cases in which there were parasitic febrile relapses was 2.7 per cent. of cases treated; but in contradistinction to the previous treatment, the average weekly number of cases in which there were parasitic relapses (febrile and nonfebrile) was only 3.9 per cent. of cases treated. Furthermore, as a curative, the result of this treatment presented a striking contrast to that of the previous one, only 12.5 per cent. of cases relapsing within the observation period of sixty days after treatment.

Intestinal Protozoal Infections in Population of Great Britain.—Among 450 civilians (men, women and children) examined by Matthews and Smith, seven, or 1.5 per cent., were found by one examination per case to be carriers of

Endameba histolytica. Among 1,098 healthy young recruits, one examination revealed sixty-two, or 5.6 per cent., to be infected with *E. histolytica.* The nonpathogenic intestinal protozoa (*E. coli, E. nana, Giardia* and *Chilomastix*) are commonly distributed in the population of Great Britain. Stools were examined by Matthews and Smith for intestinal protozoa from 548 children under 12 years of age. *E. histolytica* was found in 1.8 per cent., and the commonest protozoon was *G. intestinalis,* found in 14 per cent. Children become infected soon after they are 1 year old and from this age onward all the common intestinal protozoa are found, irrespective of age or sex. The results have been compared with those from a similar population of adults and it has been observed that *G. intestinalis* in particular is much more common among children. Investigations of whole families of which one member was known to be infected showed that in certain families infections were much more common than in the general population.

National Medical Treatment. W. J. Howarth and B. A. Richmond.—p. 274.

Hyperglycemia and Glycosuria.—Primarily Hamburger's work was done to ascertain whether or not the kidney allowed free glucose to pass through. He found that the glomerular membrane has the power of retaining free glucose, and that this power is governed by the influence of the chemical composition of the perfusion liquid on the glomerular epithelium. If this is the usual Ringer's solution, composed of sodium chlorid, 0.6 per cent.; calcium chlorid, 0.0075 per cent.; potassium chlorid, 0.01 per cent., and sodium bicarbonate, 0.02 per cent., and to it has been added 0.1 per cent. glucose, then a urine containing 0.07 per cent. glucose is excreted, 0.03 per cent. thus being retained. In the perfusion liquid the quantities of potassium and calcium with respect to each other can be altered in such a way that the retentive power need not be influenced by it. In such a case they balance each other. Instead of using potassium, this balancing can also be effected by means of radium and uranium, with doses which are determined not by equivalence in a chemical sense, but by the degree of radioactivity. The subjection of the kidney to mesothorium rays can be substituted for potassium. If the concentration of sodium bicarbonate in the Ringer's solution is raised from 0.02 to 0.285 per cent., the quantity which is present in the frog's serum, then the kidney can retain from the sugar-holding perfusion liquid more than 0.03 per cent. The artificial "urine" becomes totally free from sugar.

The results lay bare a new form of permeability—one, namely, in which cells under physiologic conditions, although quite permeable to salts, are yet impermeable to glucose, which like these is also a crystalline. The structure or configuration of the glucose molecule is responsible. The isomeric fructose and the stereo-isomeric mannose and galactose, and even the levorotary glucose (*l*-glucose) pass through the glomerular membrane. Thus the living glomerular membrane is able to distinguish normal glucose from other sugars. When, besides glucose (dextrose), fructose (levulose) occurs in the perfusion liquid, only the levulose is let through. The two sugars are separated as by a filter. What is true for a mixture of levulose and dextrose applies also to a mixture of dextrose and lactose. The lactose passes completely into the urine, the glucose is retained by the glomerular epithelium as though there were no lactose present.

Regarding the relation between glycosuria and hyperglycemia, the experiments have made clear the following: If there is a hyperglycemia of a certain degree, then the glomerular epithelium sickens and allows the glucose to pass through. The higher the degree of hyperglycemia, the stronger the permeability becomes. The toleration of the glomerular membrane for the sugar concentrations lying above the normal appears to be different for different individuals.

Febrile Acidosis in Scarlet Fever.—Thomas examined daily the urine of seven consecutive cases of moderate attacks of scarlet fever, estimating the acidity, the proportion of urea and ammonia-amido nitrogen and testing for acetones and diacetic acid, with the following results: (1) acidosis lasting from three to twelve days, reaching its maximum on the third to fifth day of the disease; (2) acetone and diacetic acid not always, though generally present; (3) urine not alkaline during administration of sodium bicarbonate from 10 to 15 grains every four hours; (4) one return of acetone, increase in ammonia nitrogen from 1.7 to 6.3 per cent., and rise in acidity from 2 to 78 per cent. tenth-normal acid, after halving the dose of soda; (5) development of nephritis later in the two patients who showed the most severe acidosis. As sodium bicarbonate did good in moderate and severe cases, Thomas has made it a routine for all with satisfactory results. It is given for a week to ten days to all children who have scarlet fever, the dose being regulated by the reaction of the urine.

Heart Massage for Resuscitation.—Bost makes an abdominal incision 4 inches long in the median line, extending from above the umbilicus well up into the xiphosternal notch. The left costal cartilages are well retracted, bringing the anterior diaphragmatic insertion will into view. A 2-inch incision, beginning 1 inch to the left of the median line carried outward behind the costal margin, cuts the fibers of the diaphragm near their insertion. A blunt instrument pushed in opens the pleural cavity, and the opening is rapidly dilated with two or three fingers of the right hand, so that the whole hand can then be passed into the thoracic cavity anterior to the pericardium. The hand is passed upward, the thumb behind the sternum and the fingers embracing the entire organ in the pericardium. The thumb compresses the right auricle and ventricle, and the base of the heart is effectively massaged. No vessels are injured in this incision, as the superior epigastric artery is internal to the incision and passes into the rectus muscle, and the musculophrenic branch enters the diaphragm through the cellular tissue behind the eighth or ninth costal cartilages and passes backward, deeper than the incision. The liver and stomach, even if prominent, offer no obstruction to this route, nor is the pericardium in danger of being opened. During the massage the parts can be pressed round the wrist of the operator so that air is not sucked in, and there is no tendency to collapse of the lung.

Heart Massage in Chloroform Poisoning.—The patient collapsed before the operation—a laparotomy—was begun. The anesthesia was complete. The heart had ceased beating. A 3-inch median incision was made above the umbilicus.

Then, with the left hand over the cardiac area externally, and the right on the under surface of the cardiac portion of the diaphragm, Harries submitted the heart to a series of rapid squeezes between the two hands at the rate of about fifty to sixty a minute. After the tenth compression the heart started beating. It went on for thirty beats at the rate of 90 to 100 a minute and then stopped. The squeezing was repeated, and after the fourth compression the heart again started beating—at first very irregularly, and stopping at intervals for two to three seconds. After about ten minutes of this irregularity, the heart beats and pulse started alternating, and the alternation continued until the onset of the final collapse preceding the patient's death sixteen hours later. During these procedures, Harries was impressed by the fact that the heart could not be felt through the diaphragm when it was not beating; but as soon as it commenced to beat, the cardiac impulse was much more distinctly felt than the apex beat on the chest wall. The color of the mucous membrane of the lips was restored after three to four beats of the heart, whereas the color of the peritoneum returned only after a dozen beats.

*Treatment of Leprosy. A. Connal.—p. 37.

Treatment of Leprosy.—In the treatment of leprosy at the Yaba Leper Asylum, Lagos, Nigeria, chaulmoogra oil has been in constant use; nastin has been employed for four years; Heiser's combination of chaulmoogra oil with camphorated oil and resorcin is given in certain cases, and sodium gynocardate was tried, the latter half of 1917. Connal says that it is difficult to reach a true estimate of the value of any one drug in the treatment of leprosy. A perusal of the case books leaves the impression that none of the four named methods of treatment is specific. Relapses have occurred in treated and untreated cases. Definite improvement has been noted in the entire absence of drug administration. The negro leper is prone to alternating optimism and pessimism. He eagerly welcomes a new therapeutic measure and tends to exaggerate any beneficial results, but despondency sets in sooner or later, when he may refuse further dosage. A history of twenty patients is given to demonstrate the results of the various forms of treatment.

Hysterical Hiccup.—The case cited by Hurst was of thirteen months' duration. It was associated with hysterical monoplegia and talipes of twenty months' duration, and was cured by suggestion during intoxication with bromid.

Hysterical Left Facial Paralysis, etc.—All of the symptoms in this case were rapidly cured by persuasion and reeducation. Hurst mentions the fact that this case is of special interest as two of the hysterical symptoms showed signs which are generally supposed to indicate organic disease, the facial paralysis involving the platysma muscle and the left-sided ptosis being accompanied by overaction of the frontalis. Any doubt which their presence may have raised in the diagnosis at once disappeared when rapid recovery occurred by pure psychotherapy.

*Peptic Ulcer after Gastro-Enterostomy. Carnot, Froussard and de Martel.—p. 1173.

Induced Convergence of Eyeball After Aerial Shock.—The uncontrollable adduction of one or both eyeballs during rotation tests is frequently associated with relics of paresis of the sixth pair. It may also be observed with injury of the eighth pair. Four cases are described with evident lesions in the vestibular or cochlear domain. The convergence of the eyeballs can thus be regarded as an indirect sign of a lesion in the apparatus of hearing, as also of injury of the oculomotor centers or of the centrifugal branch of the reflex arc affecting the motor nerves of the eye. It is a phenomenon that interests not only the neurologist but also eye and ear specialists.

Tuberculous Endocarditis.—In Barbier's case, the girl of 13 had presented severe asystole. The first signs of trouble had been noted five or six months before the fatal termination. There was no history of rheumatism, but necropsy revealed a fibrous process in the endocardium that had entailed mitral insufficiency. Other valves were also involved. The assumed tuberculous nature of the disease was confirmed only by discovery of a tubercle in the liver. Asystole develops early with tuberculous endocarditis, and death generally occurs within the year. This is the second case he had encountered within a year.

Meningeal Hemorrhage in Typhoid.—Sergent and Bertrand report a case of typhoid in a woman of 35 in which intense headache from the first was explained by the hemorrhagic character of the cerebrospinal fluid on lumbar puncture the fourteenth day, and again the nineteenth day. The fluid seemed otherwise normal and smooth recovery followed. They have not found any cases resembling this on record. Meningitis is comparatively common in typhoid, but simple hemorrhage seems to be exceptional.

Parotitis in Soldiers.—Railliet quotes certain physicians, in charge of wards to which men with mumps are sent, to the effect that many of the mumps suspects do not have mumps in fact, but acquire it in the mumps ward. The differential diagnosis is sometimes extremely difficult, as chronic or acute enlargement of the parotid glands is common, and is liable to be mistaken for mumps. Some of the men in this group say that the other members of their family have the same "large cheeks." Among the forty-three men with habitually large parotid glands, three had actually enormous enlargements; fifteen were farm workers and in about 16 per cent. there was a suspicion of lead poisoning.

During an epidemic of mumps the troops were gassed repeatedly with mustard gas, and this in 4 or 5 per cent. of the cases caused the parotid glands to become enlarged and tender. The physicians were unable to distinguish between the mumps cases and the "yperitic parotitis" except by the absence of contagion from the latter and the absence of orchitis, along with the other lesions from the mustard gas. The yperitic parotitis passed off harmlessly in about eight days.

Peptic Ulcer After Gastro-Enterostomy.—Carnot and his co-workers operated in a case of fecaloid vomiting in a man who had had a gastro-enterostomy done two years before. The laparotomy revealed a peptic ulcer with a fistula between the jejunum and the colon, close to the gastro-enterostomy opening. The ulcer had bored a communication between the small and the large intestine, and the whole mass of the adherent stomach and small and large intestine was resected in one block. The findings in this case, as they explain, confirm the peptic nature of ulcer in stomach, jejunum or duodenum, from lack of the physiologic immediate saturation of the gastric juice. In every case of fecaloid vomiting an abnormal communication between the stomach and the colon should be suspected; diarrhea favors the fecaloid vomiting. This case teaches anew the importance of keeping medical oversight of gastro-enterostomy patients as the abnormal passage of gastric juice directly into the jejunum is liable to set up ulceration at any time.

Feb. 28, 1919, **90**, No. 4

*Infant Morbidity at Bordeaux. A. Moussous.—p. 67.
*Physiotherapy of Sciatica. A. Fraikin.—p. 70.

Infant Morbidity During the War.—In resuming his course in pediatrics after the interruption of the war, Moussous comments on the effects of war deprivations on infants and those to be born soon. Among other points he emphasizes is that chilling of a new-born infant damages the fragile red corpuscles, and the laking of the blood may become manifest in the form of jaundice. Other injuries from cold explain the high mortality among young infants this last year owing to the lack of adequate heating of the homes, especially of the working classes. A good supply of milk has been available for infants at Paris all through the war, as the authorities in preparing for a siege provided an ample dairy herd. At Bordeaux the death rate among infants has been so high that for the last few months the authorities have admitted the mothers to the hospitals when nurslings have to be taken there.

Physiotherapy of Sciatica.—Fraikin reports the application of electricity, superheated air and massage, mechanotherapy and retraining of the limb in seventy-six cases of sciatic neuralgia. Three are still under treatment; forty-four were cured and eleven very much improved, while all were improved to some extent. He urges application of physiotherapy from the start instead of wasting time on drugs alone. This would prevent the sciatica from becoming so firmly established and tenacious, and would ward off neuritis and atrophy.

Correspondenz-Blatt für Schweizer Aerzte, Basel

Feb. 15, 1919, **49**, No. 7

*Influenza. II. H. Sahli.—p. 193.

Influenza.—Sahli describes the experiences with prophylactic measures at Berne. There are so many objections to masks that he does not regard them as feasible. One reason is that the conjunctiva may be a portal of entry for the germs, and another reason is that the air being forced in and out makes strong currents which sweep the bacteria along. None of the commercial masks tested were found impervious to microbes. It would be more effectual to have the influenza patient wear the mask, to protect others against him, but he would suffer more from it than others, as his respiration is already hampered by the disease. Sahli remarks, however, that the physician can protect himself against the coughing patient by having the attendant cover the patient's face with a towel or the drawn up flap of the shirt while he is examining the chest. Actual tests have shown that this precaution protects against droplet infection as effectually as the usual mask. In examining the throat, protecting goggles are worn as for diphtheria patients, and the mouth and nose are protected by the hand. All these measures have an educative influence on the patient, without frightening him as would a masked physician. By the force of example, the importance of care to prevent infection in expectoration and coughing is impressed on him. Sahli's assumption of a complex virus has already been mentioned in these columns, March 1, 1919, p. 687.

He declares that all the testimony speaks in favor of the production of immunity by an attack of influenza, especially the frequent drop of the temperature and the accompanying arrest of the lung or bronchial process. This indicates the sudden production of combative forces which annul the toxins. The fact that immunization is not absolute in every one has its counterpart in other infectious diseases. The flaring up of the influenza again when it had apparently just subsided is a further convincing proof of the influence of the immunization, as it demonstrates that the active virus was still present in the body before the relapse, but that it had been kept under control by antibodies for a time, but had finally escaped from under this control. The whole epidemiology of influenza speaks for at least partial immunization by the pandemics and the growing up of a new and susceptible generation. Between the pandemics, the influenza bacillus lives as a saprophyte, waiting for its hour to strike again. It perishes rapidly in the external world, as also apparently the *pneumococcus* and the streptococcus which form with it the complex virus. Age in itself, in addition, may protect against influenza; the elderly and infants seem to escape. Sahli adds that the cases of catarrhal fever, etc., falsely labeled "grippe," have contributed to prevent the due realization of the actual immunity conferred by influenza. It is possible that those who escape influenza during a pandemic have been imperceptibly "vaccinated" during the epidemic by inhalation of minute doses of the virus, and thus have become relatively immunized by this "inhalation vaccine."

Policlinico, Rome

Feb. 9, 1919, **26**, No. 6

*Nervous Manifestations of Influenza. G. Dragotti.—p. 161.
*Treatment of Influenza. C. Bassoni.—p. 167.
*Quinin in Prevention of Influenza. G. Betti.—p. 169.
A. Benedictus, Venice, ? -1512. G. Bilancioni.—p. 173.
*Latent Cysticercosis. P. De Tommasi.—p. 174.

Nervous Manifestations of Influenza.—Dragotti reviews the multiform organic and functional central and peripheral nervous manifestations of influenza, a long list, to which he adds epilepsy, chorea, hysteria and neurasthenia as sequelae that have been observed. Cases are known also in which exophthalmic goiter, myxedema or *delirium tremens* have followed on influenza. The influenzal psychoses of the acute period are generally of the amentia type, and as a rule subside in two or three weeks. The psychosis, however, may pass into a state of mental collapse, with stupor which may persist and become actual dementia. In other cases a neurasthenic condition, with depression and restlessness, sets up a vicious circle as the appetite is lost and the nutrition suffers. This state may keep up a longer or shorter time or even terminate in dementia. It is to this class of cases that can be attributed the large number of suicides during the pandemic of influenza. Mania developing during convalescence, about a week after defervescence, generally has a favorable prognosis. A latent tendency to progressive paralysis, dementia praecox, or a manic-depressive psychosis may be roused to activity by intercurrent influenza, or an existent phase aggravated.

Influenza.—Bassoni remarks that influenza is still present in many Italian cities, still claiming numerous victims. In the cases with complications in lungs and bronchi which do not clear up rapidly, he has found very useful injections of 2 c.c. of 10 per cent. camphorated oil with addition of 0.10 gm. guaiacol, one at 10 a. m. and one at 5 p. m. Several case reports show the prompt benefit even when the bronchopneumonia was due to secondary infection, or the case was simple influenza. The effect in his cases was so good that he is inclined to assume a specific action on the disease. The fever drops and all the symptoms abate. He supplements the injections with revulsion to the chest, proctoclysis, digitalis, or other measures as indicated. The diuretic action of the proctoclysis aids in clearing out toxins. On account of the minute doses, this treatment is absolutely harmless, he declares, and he knows of no contraindications.

Quinin in Prophylaxis of Influenza.—Betti relates that among the 1,100 malarial soldiers taking treatment at the malaria hospital on Lake Como, only five contracted influenza and they had it in a mild form.

Cysticercosis in Young Girl.—De Tommasi reports that an apparently healthy girl required amputation on account of a traumatic fracture which had refused to heal and the temperature kept high. At the amputation the subcutaneous tissue was found studded with vesicles of *Tenia solium.* There had been no symptoms at any time indicating the presence of the tenia or cysticercus.

February, 1919, **26**, Medical Section No. 2

*Adiposis Dolorosa. E. Mingazzini.—p. 49.
*Non-Nephritic Albuminurias. I. Romanelli.—p. 62.

Adiposis Dolorosa.—Mingazzini reports the case of a man of 29 who in the course of a thyroid adenoma developed painful lipomatous nodules at various points, along with slight asthenia, irritability and depression. After excision of the tumor in the thyroid, these symptoms materially retrogressed. In the 100 cases of adiposis dolorosa in women on record the thyroid was incriminated in 19, the pituitary in 5, and the ovaries in 5. No appreciable cause could be detected in 70 cases. In the 21 cases on record in men, the thyroid was incriminated in only 2, the pituitary in 4, both together in 3 and the testicle in one. No cause was apparent in 11. In the case here reported, there was a limited zone of cells in the thyroid with a chromaffin character, the altered secretion of which has been regarded as one of the contributing causes of the disease. Three pages of closely printed bibliography conclude this review of the connection between the endocrine system and adiposis dolorosa.

Non-Nephritic Albuminuria.—Romanelli emphasizes the importance of ascertaining the exact cause of the albuminuria. When the patient is restricted to a milk diet, he warns that it should never be kept up longer than two or three weeks. Bed rest is indispensable in some cases, but Teissier found in one case that even four months of bed rest failed to modify the orthostatic albuminuria. Moderate exercise and hygiene, avoidance of constricting belts, garters or corset are necessary and studying may have to be stopped on account of the mental strain and fatigue. Tonics, out of door life or hydrotherapy may be indicated, but in any event medical supervision must be maintained. The prognosis of albuminuria accompanying nervous and mental disease or emotional stress depends on the fundamental disturbance. When it is due to functional nervous disturbance it may readily subside but may reappear with equal readiness. This form of albuminuria should not be accepted in the diagnosis until all other causes for it have been eliminated. A candidate for life insurance can be accepted, but the extra risk from the lesser resisting power of the kidneys must be borne in mind. Among 308 obese persons he found albuminuria in 20 per cent. Traces of albumin up to 0.5 per thousand are common in the obese, even in those apparently free from gout, arteriosclerosis, alcoholism and hypothyroidism. In a group of 407 insured persons weighing 10 kg. or more above normal and with girth over six tenths of the height, the average age at death was 47 years and 10 months, while the other insured died at the average age of 50 years and 1 month. The proportional mortality from kidney disease in all the insured averaged 9 while it was 13.8 among the obese. He analyzes conditions further with albuminuria in the various constitutional and infectious diseases and intoxications, acute and chronic, and in the pregnant, and discusses the various views as to acceptance for life insurance. A questionnaire was sent to fifty different life insurance companies, and thirty-one described their practice. Romanelli's extensive experience in this line has convinced him that candidates with albuminuria can be accepted, as he explains, with an extra premium varying with the type of the albuminuria. This extra premium can be very small with the albuminuria of puberty, after muscular exertion, the orthostatic, and the lordotic forms, with the maximal premium for albuminuria from arteriosclerosis. The family history, longevity, kidney disease, the personal history, constitution (obesity, extreme thinness), and the blood pressure are all important. In 295 fatal cases of nephritis among the insured in one company, 54 died between 50 and 55; 40 between 61 and 65, and 20 between 66 and 70, with 4 over 75 and 4 under 30. In 99 cases the policy had run from one to five years; in 68 from ten to fifteen years; in 63 from sixteen to thirty, and in 4 for over thirty years. The general statistics give the age of the greatest mortality from kidney disease as between 51 and 55.

*Influenza at Parma. E. Ruggeri.—p. 126.
*Referendum on Influenza. P. Guizzetti.—p. 132.
The Latin Spirit and the Art of Surgery. J. L. Faure.—p. 140.
Some of the Problems of the Day. A. Ferrannini.—p. 141.

Influenza.—Ruggeri concludes his long study of influenza by emphasizing the rarity of the influenza bacillus and the frequency of a mixed virus. This association of bacteria explains the proteiform set of symptoms, the bronchorrhagia and characteristic changes in the physicochemical properties of the blood which he describes in detail. The cases with the diplococcus and staphylococcus were the graver forms, and it was in these cases that the antihemolytic power of the serum was lowest, as also the sensibility of the corpuscles.

Influenza.—In continuing this referendum, Guizzetti, describing the epidemic at Parma, states that the influenza bacillus was found in the bronchi in fourteen of twenty-seven cadavers, but none could be detected anywhere in eleven. In some cases he found an infarct in one lung, evidently from thrombosis, the result of secondary infections, to which also most of the pulmonary lesions can be ascribed. In contrast to the 1890 epidemic, he was impressed with the present marked tendency to hemorrhages in the air passages and the comparative rarity of nervous prostration following the disease.

*Typhoid Spondylitis. V. Zerbino.—p. 442.
Subacute Meningitis. J. Bonaba.—p. 450.
Acquired Syphilis in Child of Two. C. Pelford.—p. 452.

Child Welfare Work in Brazil.—Ferreira's article is the official report for 1917 of the section for protection of young children in the public health service of the state of S. Paulo, Brazil. He laments that there is only one *consultorio* for nurslings while Montevideo has seven, although the population is smaller. S. Paulo has a high birth rate, 36 per thousand, and it should have a *consultorio* for each 100,000, which would give it five. He expatiates on the fine results attained with the prizes given for the most robust children and for attendance at the infant consultations. Prizes to nursing mothers are particularly useful, and should form part of the routine of every infants' dispensary or *consultorio*.

Ataxia with Spasmophilia.—The boy of 3 had been having for nearly a month from one to thirteen attacks daily of clonic convulsions beginning in the face and extending to the extremities. The speech was peculiar, resembling the slow scanning speech of sclerosis in patches, and the incoordination in the voluntary movements was extreme. Treatment was begun in March, 1916, with 20 per cent. magnesium sulphate by subcutaneous injection, with chloral by the mouth and in enemas. In the first two weeks the convulsions became more numerous, up to thirty a day. Then they gradually declined and he has had none since May, 1916, and has seemed normal, even robust, during the years since. No details as to dosage or length of course of treatment are

hoid Spondylitis.—Zerbino remarks that the rarity of oid spondylitis confirms the truth of the saying that we find only what we look for, and we look for only what we know about. This typhoid spondylitis is encountered usually in mild or moderate cases of typhoid. The onset is sudden and the course rapidly progressive. The predominant symptom is the acute, violent pain, continuous, with paroxysmal exacerbations, generally localized in the lumbar regions, radiating to the abdominal wall and legs. It is often ascribed to overexertion or chilling during convalescence. It develops during the typhoid or convalescence or a few weeks or months after recovery. Pressure on the vertebrae, especially on the sides and front, brings on the pain. There may be a swelling in the lumbar region and even suppuration. In some cases girdle pains, sciatic neuralgia and muscular paresis complicate the clinical picture, with incontinence. The Kernig and Lasègue signs are common but not the Babinski. The course is slow but progressive. Repose for two or three months generally brings the subsidence of the symptoms, although the affection may keep up for a year or more with intervals of latency. Lumbar puncture shows the fluid under high tension but it is limpid, with high albumin content but no or very slight lymphocytosis during the acute phase. His patient was a girl of 12 who had had typhoid two months before and complained of pains and inability to use her legs. The lumbar pains developed early in convalescence. The pain kept her awake at night and there was soon incontinence of urine. No treatment was given but bed rest, and complete recovery ensued. On getting up the twentieth day, the pain returned but subsided under two more days of bed rest. After the end of the month she was allowed to get up for a time every day, and the ninth week was up all the time as the spine was apparently normal. The diagnosis was confirmed by the history of typhoid, the positive seroreaction and the favorable course.

*Acquired Feeblemindedness. H. de B. B. Roxo.—p. 17. Conc'n.
*Syphilitic Trigeminal Neuralgia. Brito e Silva.—p. 19.
Sputum-Vaccine Therapy of Influenza. U. Paranhos.—p. 20.

Acquired Mental Impairment.—Roxo declares that the symptoms of dementia praecox are liable to subside under treatment but the mind is left impaired, and he always warns the family of this contingency. Infectious diseases may leave the patient less intelligent than he was before. In some cases of postpuerperal psychoses the patients themselves realize that their mental capacity is somewhat reduced. In another case this mental impairment followed whooping cough. Under treatment for syphilis, certain cases of delirium which seemed to be permanent have retrogressed but some mental impairment is always left. Small doses of neoarsphenamin have proved exceptionally useful in these conditions. It seems to free the nerve cells from the toxin and tone them up. Sodium nucleinate and sodium arseniate seem to have a similar action, combating the toxic disturbance in the metabolism of the nerve cells. These or their equivalent or an organ extract should be tried in all cases of acquired mental impairment, from the toxic products resulting from some upset in the balance of the endocrine system or toxi-infection of other nature.

Syphilitic Trigeminal Neuralgia, etc.—Brito e Silva discusses the various manifestations from the fifth nerve for which syphilis may be responsible. The neuralgia grows worse at night, and this, in connection with the inefficacy of drugs which usually relieve neuralgia, point to syphilis, and this presumption is confirmed by the rapid cure under specific treatment.

Gaceta Medica de Caracas

Jan. 15, 1919, 26, No. 1

*Oxytocic Action of *Quinin.* L. Razetti and others.—p. 1.

Oxytocic Action of Quinin.—Razetti publishes an appeal to physicians practicing in malarial regions asking whether they have given quinin to pregnant women, and whether they had noted any oxytocic action from it during parturition, and whether they attribute any abortions or premature deliveries which they may have observed to the malaria or to the quinin. Ayala says that during his sixteen years of practice in a malarial region he gave quinin to pregnant women and never noted any elective action on the quiescent uterus. When the uterus is already contracting, he thinks that quinin tends to make the contractions more vigorous. Razetti is an obstetrician in a malarial region, and his experience is against the assumption of any oxytocic action by quinin at any time. He is convinced that others who state the contrary have mistaken the abortive influence of the malarial, typhoid or influenza infection for the action of the quinin. When there are signs of impending abortion from the influence of malaria he gives quinin freely, as this as yet is the only means to dominate the malaria, the true cause of the abortion. Ruiz is convinced that nothing but the quinin was responsible for the abortion in a case he describes in which a young and robust woman, four or five months pregnant, contracted malaria on a trip, but the fever was not high, and treatment was begun at once. A few hours after she had been given one or two large doses of quinin, labor pains and vaginal hemorrhage indicated impending abortion. Abortion is comparatively common in malaria, typhoid, etc., when the disease is well under way, but never in the incipiency of the disease. Hence he reiterates that we must accept a possible oxytocic action in this case and in certain women. Machado, on the other hand, from fifty years of practice, including fifteen in a hotbed of malaria, insists that it is impossible for quinin to have any oxytocic action as he always gave it freely regardless of pregnancy and impending abortions, and never had to regret having done so.

*Influenza at Caracas. F. A. Risquez.—p. 13.
*Influenza at Barlovento. E. P. de Bellard.—p. 18.

Influenza in Venezuela.—Risquez relates that fully 75 per cent. of the 100,000 inhabitants of Caracas developed influenza in October and November. The death rate was higher than elsewhere, compared with the population, but much lower than in many places in comparison to the numbers attacked. The corresponding figures in the American army, he says, were 1.3 and 6.3 per cent., while at Caracas they were 1.4 and 1.9 per cent. He was impressed with the number of cases of relapse, the symptoms returning after three or five days of apparent recovery. These relapses occurred only in those who had got up out of bed and become chilled. He never witnessed any pulmonary complications in patients who stayed in bed three, four or five days after defervescence. He adds that as 80 or 90 per cent. of the cases run a mild course of only three days, and as the disease seems to confer immunity, and as public and individual prophylaxis is scarcely realizable, the attention must be focussed on warding off grave complications.

In de Bellard's experience in the Paez district, 63 per cent. of the inhabitants had the disease and 15 per cent. of the cases involved the lungs, with a mortality of 25 per cent. in this group. In one town, 2.31 per cent. of the inhabitants died. About 78 per cent. of the deaths were in persons under 30. The pulse in the grave cases suggested suprarenal insufficiency or resembled that of traumatic shock. An intestinal choleriform type was comparatively common. It did not respond to emetin.

*Acute Nephritis. S. Pascual.—p. 49. Cont'n.
*Influenza. IV. R. Velasco.—p. 54.
Is Vision Possible Without Eyes? G. Beritens.—p. 55.

Acute Nephritis.—Pascual passes in review the whole field of acute nephritis from the brief and curable form manifested by albuminuria, tube casts and oliguria, as in typhoid, and the nephritis that speedily kills from anuria, as with mercuric chlorid poisoning. Tuberculous nephritis may begin with the usual onset of acute nephritis but the polyuria up to 2 or 3 liters is characteristic, and inoculation of guinea-pigs clears up all doubt. Syphilitic nephritis is distinguished by the intense albuminuria, the extensive edema and the retrogression under specific treatment. Nephritis in scarlet fever may first manifest itself with convulsions, or with intense edema or albuminuria. In a recent case of mercuric chlorid poisoning, the anuria was accompanied by coma alternating with delirium, and there was 0.3 gm. of urea per thousand in the blood. Death occurred the fifth day without edema or uremic symptoms.

Influenza.—Velasco states that metrorrhagia was noted in 62 per cent. of his cases of influenza in women. Abortion or premature delivery was common and often fatal, but the fetus was living when born. The congestion in the uterus entailed hemorrhage which acted like a foreign body, leading to contraction and expulsion of the uterus contents. He comments on the exceptionally high death rate of physicians from influenza. They come in contact with the graver cases, with the more virulent germs, and are more exposed to secondary infection than other people.

*Epitheliomas of the Hand. A. Piga and A. Ferrán.—p. 5.
*Oxaluria and Effects on the Nervous System. C. Juarros.—p. 21.
Vacuum Extraction of Cataract. J. S. Fernández.—p. 35.
*Induced Diplopia. J. S. Fernández.—p. 37.
Cervical Ribs. A. Perera.—p. 40.
*Eclampsia and Venesection. V. Aza.—p. 44.

Epitheliomas of the Hand.—Piga and Ferrán declare that radiotherapy has been too long neglected in treatment of epitheliomas of the hand. Surgical measures are generally advocated, but they insist that radiotherapy should be given the preference in certain cases. They review the history of such lesions from 1757 to date, and the anatomic and histologic findings, with illustrations of the normal and the pathologic details. Epithelioma is more common in men than in women, and on the back of the hand rather than on the palm. They have encountered about three in 125 cases of superficial cancer, but as a rule they are observed only in about 1 or 2 per cent. In treatment, a combination of roentgen and radium exposures and surgery has given good results in some cases. With melanic epitheliomas they advise to abstain from radiotherapy, although Béclère has reported the cure under it of a melanic sarcoma. The consensus of opinion, however, is against it. If the cancer does not show prompt improvement under the radiotherapy, they advise recourse at once to surgical measures. Electrocoagulation is contraindicated for these lesions as there is very little soft tissue in the region, and the tendons resist the procedure as they determined on the cadaver. It is also liable to make too much demands on the patients as they are usually elderly and debilitated. For this reason, also, great care must be taken not to allow the dressing to compress or constrict the parts too much. They warn further that every suspicious wart on the hands should be submitted to radiotherapy. They append considerable bibliography.

Oxaluria.—Juarros describes ten cases in which neurasthenia or other nervous symptoms accompanied oxaluria. The latter may be of alimentary origin, or may be a consequence of hyperchlorhydria or intestinal autointoxication or diabetes, or there may be a constitutional tendency to neuroses, aggravated by the oxaluria, or the latter can be traced to the endocrine system. His cases are examples of these different types. In the cases with hyperchlorhydria, correction of this banishes the oxaluria, and with this the nervous disturbances for which it was responsible, but nervous disturbance from other causes persists unmodified. Regulation of the diet will reveal and cure alimentary oxaluria. In two of the cases the oxaluria aggravated preexisting nervous disturbance, and these became attenuated but did not disappear altogether under treatment of the oxaluria. In one group of cases, the oxaluria induced phosphaturia. Treatment of the latter alone is futile as the oxaluria is solely to blame; it may even aggravate the oxaluria and its resulting disturbances. In treatment, foods liable to produce oxalic acid should be avoided; this includes gelatinous meats, pigs' feet, giblets and shell fish; stimulants, acids and liquor, and foods rich in oxalic acid, spinach, cress, peppers and prunes. Lime salts, he continues, promote the formation in the intestines of an insoluble calcium oxalate, while magnesium salts neutralize gastric acidity and help to keep the oxalic acid dissolved in the urine. Sodium, potassium and magnesium citrates form a double salt with calcium. He adds that acid sodium phosphate in large doses may help to dissolve oxalate calculi.

Diplopia as Optical Illusion.—Santos Fernández calls attention, with illustrations, to the peculiar illusion noticed when the tips of the fingers are touched together, held about 30 or 40 cm. from the face, and then they are gradually drawn apart a few centimeters. Between the tips there appears a mirage of the tips, partly bridging the space, and remarkable in that the tips point in opposite directions from the nearest tips.

Eclampsia and Venesection.—Aza warns that venesection is called for in eclampsia only when the blood pressure is abnormally high. Enough blood should be drawn to reduce the pressure to normal, and the physician should always consider the advisability of saline infusion afterward.

*False Cancers in Stomach and Rectum. J. Blanc Fortacin.—p. 65.
**Analgesia for Inoperable Cancer.* J. Blanc Fortacin.—p. 70.

False Cancer in Stomach and Rectum.—The symptoms and roentgen findings in Blanc Fortacin's case indicated a cancer in the lesser curvature of the man of 44. Gastrectomy was contemplated, but then the man's child was seen for the first time. The evident signs of inherited syphilis gave the clue to the father's lesion, and under specific treatment the supposed cancer disappeared completely. The Wassermann reaction confirmed the diagnosis. In another case the stenosis from a severe presumably cancerous ulcerative process in the rectum compelled an artificial anus. This relieved the rectum and it began to heal, but further symptoms seemed to show that the rectal process had invaded the adjoining abdomen. A tumor and enlarged glands could be palpated and the debility was extreme. Vigorous treatment as for syphilis gave no relief, and as a last resort heliotherapy was applied to the abdomen as this could do no harm although no benefit was anticipated from it. The tumefaction in the abdomen subsided under it while the rectal lesion continued a progressively favorable course. The abdominal tumor must have been an isolated connective tissue lesion, secondary to the rectal lesion, which probably was of tuberculous nature. The heliotherapy modified favorably the abdominal lesion by direct action and, indirectly, the rectal lesion by the tonic and antiseptic influence from the actinic rays. These assumptions were confirmed by the course of the case. The heliotherapy could not have exerted such a beneficial influence, however, if it had not been for the preceding operation to divert the feces and give the rectum a chance to heal.

Analgesia for Inoperable Cancer.—Blanc Fortacin reports prompt and durable relief of the unbearable neuralgic pains accompanying extensive pelvic cancer. He accomplished this by intraspinal injection of 2 c.c. of a 10 per cent. solution of quinin and urea hydrochlorid. During the twelve days to date of writing the relief from pains has been so great that morphin has not been required. Before this the woman had required repeated injections of morphin. The intraspinal injection induced a transient febrile reaction, with headache and vomiting, but there were no motor or vasomotor by-effects.

*The Oculocardiac and the Nasocardiac Reflexes. M. Bañuelos and R. A. Ortiz.—p. 97.

The Oculocardiac and Nasocardiac Reflexes.—Bañuelos and Ortiz report the results of testing fourteen persons repeatedly for the oculocardiac and the nasocardiac reflexes. They found them both inconstant in the same person at different times, but the nasocardiac reflex was more constant and more pronounced than the other.

Revista Medica del Uruguay, Montevideo

November, 1918, **21**, No. 11

*Sarcoma of the Middle Ear. E. Regules (hijo) and J. M. Alonso.—p. 665.

*Paroxysmal Tachycardia and Menstruation. F. B. Del Pino.—p. 674.

Generalized Trychophytosis in Three Months Babe. J. May.—p. 680.

*Trichinosis in Man. T. Regules.—p. 681.

Coincidence of Nodose and Polymorphous Erythema. B. Vignale.—p. 693.

Sarcoma of the Middle Ear.—Regules and Alonso say that the case they report is the first case of sarcoma on record in which the diagnosis of cancer of the middle ear was made before the tumor had invaded the auditory canal or the external portion of the mastoid. With Grasser's case of endothelioma and Neumann's of metastatic adenocarcinoma, it forms a group of three cases in which the membrane was intact. Their patient was a woman of 35 with left peripheral facial paralysis and trigeminal neuralgia with total deafness on that side. There was nothing to suggest an intracranial tumor. The tympanum was red but there was no discharge. Paracentesis caused profuse hemorrhage and gave the sensation of a tumor mass filling the tympanum. The operation showed that the very small vascular tumor penetrated a dehiscence in the bone but the walls and ossicles were otherwise apparently normal. The wound was left open for the purpose of applying radium treatment. The case is compared with 38 on record, including 19 of epithelioma, 14 of sarcoma, and 2 of malignant cystadenoma. The tendency to metastasis is slight, and the lymph glands are seldom involved. Only 4 of the above cases presented manifest metastasis in cerebellum, lung or ribs or involvement of the glands.

Paroxysmal Tachycardia.—Del Pino's patient is a woman of 48 who had always been healthy until six years ago when a child in her arms was killed by a stray bullet during an Easter celebration. Soon after this, she noticed occasional attacks of tachycardia with fatigue and sense of oppression in the chest. Finally they returned regularly at each menstruation. The symptoms disappeared with the menstruation but returned each month with it. There was no fever, no tendency to goiter, but the pulse was uncountable and the heart beat 170. Treatment consisted of rest in bed during the paroxysms with digitalis to ward off dilatation of the heart during the tachycardia, supplemented with ovarian treatment.

Trichinosis.—Regules describes a case in a man of 43, healthy until recently, with seven healthy children. It is the first case recorded in Uruguay although the disease has long been known in swine there. Probably certain human cases have been labeled typhoid; the diazo reaction is positive; the spleen may or may not be enlarged, and Stäubli has reported cases with rose spots suggesting typhoid. Differential points are the edema in the face, especially in the eyelids, and the pains and intense and persisting rigidity of the muscles, the abolition of the knee-jerk, Kernig's sign, and leukocytosis, but eosinophilia of from 20 to 60 or even 80 per cent. is the most characteristic sign. Serum diagnostic tests with an alcoholic extract of trichinae from the muscles have also proved instructive.

*The Electrocardiogram After Heart has Stopped Beating. W. Einthoven and F. W. N. Hugenholtz.—p. 310.

*Epidemic Typhus on Island. Aldershoff and Broers.—p. 319.

*Multiple Cases of Mongoloid Idiocy in Family. W. M. van der Scheer.—p. 328.

Paratyphoid B or Colon Bacillus? J. S. Rudelsheim.—p. 336.

Poisoning from Homeopathic Remedy. B. D. De Haas.—p. 338.

The Electrocardiogram After the Heart Stops Beating.—Einthoven and Hugenholtz have confirmed the statement of Mines, Noyons and others to the effect that the electrocardiogram record keeps on long after the index has stopped recording any muscular contraction in the heart. This is generally accepted as testifying to the mutual independence of the muscular contraction and the electric waves, but later research here reported apparently disproves this. The electrocardiograph is extremely sensitive, while the contrivances hitherto used for recording the muscular contractions are much less sensitive, and the impulse of the heart beat is not enough to overcome the friction and inertia of the comparatively clumsy recording instrument. They give an illustrated description of a simple apparatus in which a long index is held in a copper cap soldered to a fine wire stretched taut between two thumbscrews in a small open frame. By turning the thumbscrews the index is raised or lowered, and this tightens a thread which is tied to the index, the other end of the thread fastened to the ventricle or auricle. The whole is extremely light and sensitive, with the minimum of friction and inertia. With this delicate instrument the contractions of the heart are recorded. They keep pace step by step with the electrocardiogram record, rising and falling synchronously, and with parallel intensity throughout. The research was done on the isolated frog heart under the action of different poisons or other influences. The tracings reproduced demonstrate that the mechanogram and the cardiogram are indissolubly connected with each other. A factor that may have contributed to the hitherto prevailing erroneous interpretation of the apparent arrest of the heart beat, while the electric phenomena kept on, is that, under the influence of the drugs used in the research, both the heart beat and the electric waves may have been modified so that one or the other or both may have presented an abnormal course.

Epidemic Typhus on Island.—Aldershoff describes a small epidemic of typhus on the island of Urk for which no source of infection could be discovered except that a similar epidemic had occurred on the island thirty years before, with occasional cases since. He remarks that pediculosis is universal among the 3,000 inhabitants of the island, and the small spread of the epidemic suggests immunization from previous attacks. He was impressed by the large proportion of mild ambulatory cases, but a few very severe cases testified that the virulence of the germ was not always attenuated, as in Brill's disease. Another peculiar feature of the epidemic was that the agglutination with the Weil-Felix proteus bacillus strain was constant and pronounced, but it was almost paralleled by the agglutination of an old strain of what was supposed to be paratyphoid A.

Familial Mongoloid Idiocy.—Van der Scheer has been able to find on record only eleven families in which more than one of the children presented mongoloid idiocy. But the Holland town of Lisse has two families in which there are two or three mongoloid idiots. In one of the families two idiot girls were born and then three normal sons. The parents were young and healthy, but the woman had been severely frightened by a dog at the third month of her first pregnancy, and another fright was experienced at the sixth month of her second pregnancy. In the other family, two boys and one girl are mongoloid idiots while two other boys are normal, one the first born and the other the last born in the family. The mother's father had been a habitual drunkard and her grandmother and an uncle had been mentally deranged. No instances of multiple occurrence of idiocy are known in the families of eight idiots in the Netherlands State Institution for the feebleminded. The article is illustrated, and Van der Scheer urges examination with special care of the stillborn children and miscarriages in families with a mongoloid idiot; also research on the influence of emotional stress on the course of a pregnancy.

Mededeelingen v. d. Burg. Geneesk. Dienst, Batavia

1919, No. 1

*Hygienic Conditions in United States, Panama and Cuba. C. W. F. Winckel.—p. 1.

Hygiene in Panama, Cuba and the United States.—Winckel is a health officer in the Netherlands East Indies, and the Netherlands minister for colonial affairs sent him to this country to study conditions here. His illustrated official report deals mainly with measures for prophylaxis of malaria, plague, hookworm and typhoid fever, besides the eradication of yellow fever in Cuba and Panama, and the general hygiene of the Canal Zone. The trip was made in the first half of 1917 on a year's leave of absence. The daily papers in this country mentioned at the time his presence at different points, conferring with the public health authorities and investigating their methods. His report fills eighty-four pages, written in parallel columns of Dutch and English. He remarks of the public health service in Cuba that possibly it owes its model efficiency to the fact that the chief of the service is a member of the cabinet, and hence a person of authority, entirely free from municipal and communal jurisdiction. Panama and Colon are likwise managed from the central administration office of the Canal Zone.

*Japanese River Fever. T. Kitashima and M. Miyajima.—p. 237. In German. Conc'n.
Bacteriology of Influenza. I. Okawara, T. Tanaka, Y. Watanabe, R. Koyama and T. Sato.—p. 335. In English.

Tsutsugamushi Fever.—This concluding instalment of this monograph by Kitashima and Miyajima is accompanied by eight plates, most of them colored, showing the acaris responsible for Japanese river fever, its habitat, etc. The extensive research on the therapeutic aspect gave constantly negative results. Hence attention must be centered on individual prophylaxis to protect against the bites of the mite. They expatiate on the resemblance between exanthematous typhus, Rocky Mountain spotted fever and this tsutsugamushi disease: The type of the fever is similar, keeping on a high level when the maximum of 40 or 41 C. is reached; the eruption; the character of the virus which has little resisting power against physical and chemical actions, and cannot be filtered through porcelain; also in the nature of the causal agent, which is found in abundance in the blood, on the blood cells, especially the leukocytes; also in the mode of infection, the virus being inoculated by the bite of an insect or mite which must be regarded as the intermediate host. On the other hand, monkeys that have had tsutsugamushi disease contract typical typhus when inoculated, and vice versa. They add that although the virus cannot be filtered through porcelain yet it evidently belongs in the same group with the filtrate virus of yellow fever, dengue, etc. They cite seventy-three articles that have been published in Japan on the subject, and others published elsewhere on this group of diseases in reference to the etiology—a total of 165 articles. They have been studying the problem of the germ of this disease for fourteen years. The field mouse seems to be the natural host of the mite in question, but the spirochetes cultivated from the field mice do not seem to be pathogenic for other mice or for guinea-pigs. They add that the ultramicroscopic causal agent is still as much of a mystery as ever, leaving a wide field open for experimental medicine.

Mitteilungen a. d. med. Fakultät. d. k. Univ. Tokyo

Nov. 26, 1917, **18**, No. 3, German Edition

*Lipoid Cleavage Products in Spinal Cord. F. Shionoya.—p. 285.
*The Donath-Landsteiner Reaction. Y. Nakamura and S. Yabe.—p. 302.
*Japanese Drugs. W. Sakai.—p. 317.
*Acromegaly without Pituitary Tumor. S. Yamada.—p. 411.

This issue of the *Mitteilungen* was not received until March 7, 1919. A number of fine plates accompany Yamada's article and one Shionoya's.

Lipoid Cleavage Products in Spinal Cord.—Shionoya refers to the lipoid cleavage products in the secondary degeneration of fibers in the human spinal cord, giving a colored plate of the findings in one of eleven cases described. The patient in this case was a man of 32 with amyotrophic lateral sclerosis.

The Donath-Landsteiner Reaction.—Nakamura and Yabe report the findings with this reaction in relapsing fever, malaria, paroxysmal hemoglobinuria and syphilitic affections. The "cold hemolysis" was found in tabes, in relapsing fever and in progressive paralysis, so it is not peculiar to paroxysmal hemoglobinuria as hitherto accepted, and it may occur without the latter.

Japanese and Chinese Drugs.—Sakai relates the outcome of pharmacologic and experimental tests of four drugs that have been in use in Japan and China for centuries, ginseng, cnidium, ligusticum acutilobum and the root of the angelica anomala L.

Acromegaly Without Pituitary Tumor.—Yamada's patient was a young merchant, robust until at 17 he noticed that hands and feet were growing larger. On several occasions he presented edema, hypoesthesia of the calves and finally lassitude and fatigue, with death at 21 from acute beriberi. The pituitary was found apparently normal. Probably the entire polyglandular system was involved in the production of the acromegaly.

Influenza.—Ustvedt relates his experiences at the Ullevaal Hospital up to September, 1918. There were 197 cases of influenza pneumonia, with 32.5 per cent. mortality. He reviews further the previous epidemics of influenza, beginning with the first in 1173. Since 1890 there have been cases reported every year from the 10,461 cases in Christiania in 1890 and 5,278 in 1901 to the lowest figure, 138 in 1906. The cases listed as influenza in the last few years may have been merely a catarrhal fever. This is the more probable as the cases were restricted to the winter months while influenza usually occurs at other seasons. The elderly in his district seemed to escape the disease in 1918.

Necropsy Findings in Influenza.—Hansteen relates from the same hospital that Pfeiffer's bacillus was very rarely encountered but a streptococcus was found very common, in some cases in pure culture in the lungs, in others in the heart or spleen. In many cases it was found in the lungs associated with staphylococci, pneumococci or other bacteria. Suppurative meningitis was found in some of the cadavers, hemorrhagic encephalitis in one, and acute verrucous endocarditis in four.

Streptococci in Influenza.—Schønfelder describes the streptococcus found in many of the cases at the Ullevaal Hospital. It was found often nearly in pure culture in the influenza lung, in the spinal fluid with influenza meningitis, in the blood, and in the pleural effusions. It was only slightly pathogenic for animals, which was also the case with Pfeiffer's bacillus.

Complications of Pseudo-Influenza.—Keyser has had 308 cases since last June of what he calls false influenza. He says that it resembles true influenza except for the bacteriologic findings. Among the complications encountered were pneumonia in two cases, conjunctivitis in fifteen; tuberculous epididymitis, herpes zoster and acute meningitis in one case each. One previously healthy man complained of trigeminal neuralgia and tenderness and swelling of large numbers of glands at different points.

Hypersusceptibility to Certain Drugs.—Schiøtz gives an illustrated description of a case of lymphosarcoma in a young woman in which, the day after beginning to take potassium iodid, a severe pemphigus developed on hands and face, the vesicles suppurating. He theorizes to explain such an idiosyncrasy as an explosive catalytic process induced by the action of normal chemical organ products on the nervous system, the process started by the presence of some exogenous catalyzer, in this case potassium iodid. Waetzold has demonstrated that epinephrin and faradization have a much stronger effect after iodin than otherwise. Schiøtz recalls that the symptoms with such an idiosyncrasy differ entirely from those with an intoxication. Notwithstanding the variety of the symptoms induced by hypersusceptibility to a drug or food, they all fit into the frame of disturbances resulting from an upset in the balance of the vegetative nervous system, as he explains in detail. Either the sympathetic or the autonomous system becomes impaired under the influence of the drug or food in question, and then the other system gets the upper hand and the symptoms follow. Persons with an unstable nervous system are peculiarly liable to develop these idiosyncrasies. Research in hospitals, etc., might reveal that women were more inclined to them than men. He has noticed further that there may be periods in which the vegetative nervous system is more unstable than at other times. A drug may be taken over a long period without intolerance, and then suddenly, if its administration coincides with some transient period of extra instability, the idiosyncrasy may become manifest. Menstruation eruptions and menstruation idiosyncrasies have been recorded. Anaphylaxis is an acquired specific hypersusceptibility, and the symptoms with an idiosyncrasy resemble in many points the clinical picture of anaphylaxis, and suggest that the same measures might prove effectual in each. Atropin has proved effectual in the heart and respiratory disturbances from morphin poisoning, and atropin has also been found to cure urticaria in some cases. Lewin asserted long ago that belladonna may enable persons to take potassium iodid who under other conditions are unable to tolerate it, but his statement was not confirmed by others. Nägeli has recently reported a case in which injection of an arsphenamin preparation was always followed by an eruption, but a preliminary injection of epinephrin warded this off. The analogy with anaphylaxis here is most striking, Schiøtz remarks. He discusses further the differential diagnosis of hysteria from idiosyncrasy, declaring that the latter is only one link in a long chain which includes asthma, serum sickness, acute circumscribed edema, certain forms of purpura, hay-fever and periodical vomiting with acetonemia. There is a wide field for research here. Cases should be studied by analysis of the urine (acetone), the blood should be examined for eosinophilia, leukopenia; noting the sex and the age as predisposing factors.

Drugs to Aid Delivery.—Benestad discusses quinin and pituitary extracts, with ten pages of bibliography, giving the details of 111 cases in which one or more of these drugs were applied. The maximal dose of pituitary extract, he reiterates, must never be higher than twice the ordinary therapeutic dose. As a rule, one injection during the dilating phase and one during the phase of expulsion are all that should be used. The therapeutic dose of pituitary extract should correspond to not more than 0.10 gm. of the gland substance. In 71 per cent. of his cases delivery proceeded spontaneously after a single injection of the pituitary extract. The failures were due to causes which the drug could not influence, extra large size of the fetus, rigid parts, etc. He advises operative delivery if the birth does not progress during the hour following the injection in the second stage of labor when the labor contractions are growing weaker. The effect seemed the same in primiparas and multiparas.

*Deafmutism in Sweden. E. Bergh.—p. 507.

Deafmutism in Sweden.—Bergh's extensive investigation of deafmutism in the Malmöhus district revealed 383 deaf mutes, that is, about 8.4 per ten thousand inhabitants of that region. The proportion was 10.9 in the towns and only 6.8 in the rural districts. Only 28.2 per cent. of all were known to be congenitally deaf. Six pages of literature are appended and all this material is discussed from the economic, national, etiologic and social standpoints, as well as prophylaxis and treatment, the whole filling nearly 200 pages. In the district investigated, direct transmission of congenital deafmutism to the offspring does not seem to be much of a factor in deafmutism. On the other hand, deafmute marriages result in few offspring. Prohibition of consanguineous marriages would not accomplish much as the parties could get married in other countries or cohabit without marriage. The most important factor in deafmutism is seen by these researches to be infectious diseases, and it is against these that prophylactic measures should be directed.

*Habitual Constipation. VIII, T. E. H. Thaysen.—p. 91. Conc'n.

Habitual Constipation.—Thaysen calls his method of treating habitual constipation the alaxative method. It is based to a certain extent on Dubois' principle but he does not accept Dubois' assumption that the constipation is the result of psychic inhibiting processes. The principle of treatment is absolute abstention from laxatives and training the bowels to move at a certain hour every day. Dubois advises suppressing the desire for defecation at any other time than the appointed hour, but Thaysen advocates heeding it and yielding to it whenever it may occur, but always going to stool regularly, at the appointed time every day, regardless of whether there is a desire or not. The idea that it is impossible for one to have a normal passage certainly aids in maintaining the constipation, and emotional stress might check bowel functioning for a brief time, but otherwise he does not believe in a psychic etiology for habitual constipation. Some even regard the matter from the opposite point of view, maintaining that habitual constipation is the cause of psychic disturbance, neurasthenia, etc. His distinction between what he calls habitual constipation and ordinary constipation was outlined in the summary in The Journal, March 15, 1919, page 838, of an earlier instalment of his article. He emphasizes that the danger from going a long time without defecation is not so great as generally supposed. He never witnessed any signs of inflammation even when a patient went up to fourteen days without stool.

He gives the patient a card with printed directions to rise, for instance, at 8; at 8:15 drink a glass of tepid boiled water; at 8:30 a light breakfast; at 9 go to the W. C. and strive to have a passage, devoting fifteen minutes to it if necessary. At 9 p. m. eat some stewed fruit; retire at 10. Of course these hours can be altered to suit the patient's habits, but always having the meals regular and ensuring plenty of sleep. If there is a desire for defecation during the day it is to be yielded to. This aids in recalling to life the torpid defecation impulse. If the main defecation impulse is found to come at some other hour than in the morning, this hour can be appointed for the regular time and everything done to make this the center of the training of the bowel. With this alaxative treatment, natural movements usually begin by the third or fourth day. If the feces are very hard at first, a small oil enema or cocobutter suppository will remedy this.

When dyspepsia accompanies habitual constipation it generally develops several years after the onset of the latter; the pain at the cardia comes on soon after or during the meal, and the position, secretion and motor functioning of the stomach seem to be normal, or there is some slight secretory anomaly (mainly in men), or motor disturbance (mainly in women). The constipation further is of the habitual type, that is, it became a settled habit before the age of 26 in women and of 31 in men. The dyspepsia depresses the vitality and this sets up a vicious circle. Anorexia in these cases is usually of psychic origin, and the patient must have his interest in food aroused. Psychotherapy here may prove more successful than the most skilful dietetics. If the alaxative treatment fails completely, the next best treatment is with rectal injection of warm oil, 250 c.c. to be retained over night. The introduction of this method has wrought a revolution in the treatment of constipation, he adds, but it has the disadvantage of being more symptomatic than causal.

NONSPECIFIC PROTEIN THERAPY IN INFLUENZAL PNEUMONIA

A CONSIDERATION OF THE ACTION OF TYPHOID PROTEIN *

DAVID MURRAY COWIE, M.D.

AND

PAUL WEBLEY BEAVEN, M.D.

ANN ARBOR, MICH.

Because of our experience with the treatment of arthritis and other infections by the intravenous injection of typhoid protein,[1] our attention was drawn to the possible value of this method of treatment in influenzal pneumonia, particularly from the point of view of stimulating polymorphonuclear leukocyte production. We had not, however, had any experience with superimposing an increased temperature on an already febrile condition. For this reason and because of our lack of definite knowledge of what was to us a new pneumonia, we hesitated to try so drastic a measure in the early part of the epidemic. The present report records the treatment of nine cases; a small number, but sufficient to afford some trustworthy knowledge.

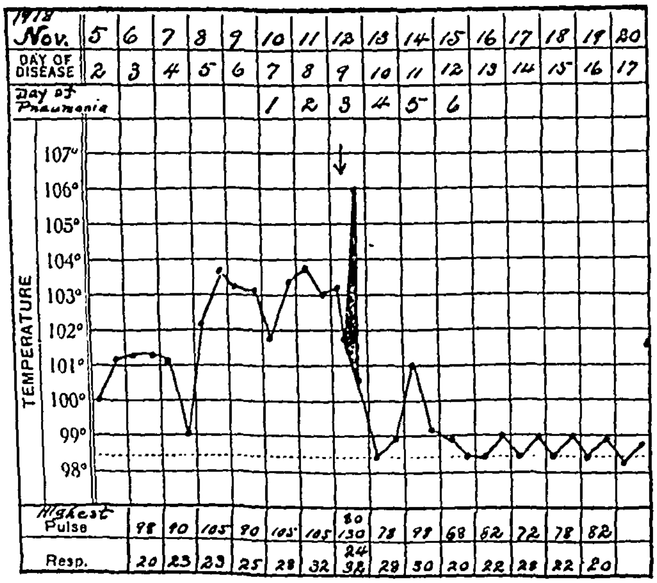

Chart 1.—Temperature, pulse and respiration in Case 1.

REPORT OF CASES

Case 1 (4385).—Dr. H. entered the contagious hospital, Nov. 5, 1918, with influenza, the second day of the disease. He developed pneumonia on the seventh day of the disease. Five hundred million dead typhoid bacilli were given intravenously, November 12, the third day of the pneumonia. The reaction is shown in Chart 1. In forty-five minutes the patient reacted with a severe chill. The temperature reached 106 F. Previous to the injection the temperature was 101.8. The following morning the temperature was 98.6, and remained normal except for one day, when it reached 101, promptly returning to normal. The signs in the chest gradually cleared up, but the spoken voice was still exaggerated over the right base on discharge.

This patient had a frank pneumonia of the lower right base. The urine showed albumin and casts. The leukocytes were as indicated in Table 1.

Case 2 (4388).—Harold F. entered the contagious hospital with influenza, Nov. 7, 1918, on the fourth day of the disease. The first signs of pneumonia were discovered, November 11, the eighth day of the disease. Five hundred million dead typhoid bacilli (typhoid vaccine) were given intravenously at 10:30 a. m. A typical protein paroxysm followed. At the time of the injection, the temperature was 102.8. Half an hour later (11 a. m.), it was 100; at noon, 102; at 4 p. m., 98.8; at 6 p. m., 98.6—seven and a half hours after the injection. On the 13th at 8 a. m. the temperature had reached 103. A second intravenous injection of 500 million was given at 10:45 a. m., at which time the temperature had reached 99 F. A typical reaction followed, but the temperature did not go above 101.4. The chill began in thirty minutes and continued thirty minutes. Seven and a half hours after the injection, the temperature had reached 95.9, and it did not go above normal thereafter.

This patient had a well-marked double pneumonia, the right side being mostly involved. The urine never showed albumin or casts. The leukocyte counts are given in Table 2.

November 13, two days after the second intravenous injection, consolidation of the left base was the same as before the injection. There was now a slight patch on the right side below the angle of the scapula which we had not discovered before. November 25, physical signs were still present but were diminished. The patient was discharged. He was seen again two weeks later, and there was still evidence of the previous consolidation in the left base. He was feeling perfectly well and had been so since the second injection. It was difficult to keep this patient in bed after the second injection.

TABLE 1.—LEUKOCYTE COUNTS IN CASE 1

Nov. 12, 1918, first and only injection, 500 million dead typhoid bacilli:	Leukocytes	Polys. %	Total Lymph. %
Control 24 hours before injectiton	3,600	57	43
Control 12 hours before injection	3,300	55	45
Control 3 hours before injection	3,000	58	42
½ hour after injection	4,200	53	47
4 hours after injection	3,600	92	18
6 hours after injection	7,200	87	13
9 hours after injection	5,500	85	15
24 hours after injection	4,500	49	51
48 hours after injection	4,600	62	38

[1] Cowie, D. M., and Calhoun, Henrietta: Nonspecific Therapy in Arthritis and Infections, Arch. Int. Med. 23: 69-131 (Jan.) 1919.

Case 3 (4443).—M. G., boy, aged 13, entered the contagious hospital, Dec. 13, 1918, with influenzal pneumonia in the left base, the fifth day of his illness. We have called this the first day of his pneumonia. The patient looked in fair condition. The process did not seem to be marked until the fourth day in the hospital, December 16, when distinct new areas were discovered in both bases. He still did not seem very ill. He was sleeping and eating well and did not spit blood. His lips were slightly cyanotic. The temperature was 104.8 in the morning. At 4:45 p. m. 1 billion dead typhoid bacilli were given intravenously. At this time his temperature was 105.6. Forty minutes later he had a severe chill lasting twenty-two minutes. The temperature did not increase, but an hour and fifteen minutes later it was the same, axillary. The following morning at 8, the temperature was 97. The patient was definitely better subjectively and objectively. The temperature remained down all of this day.

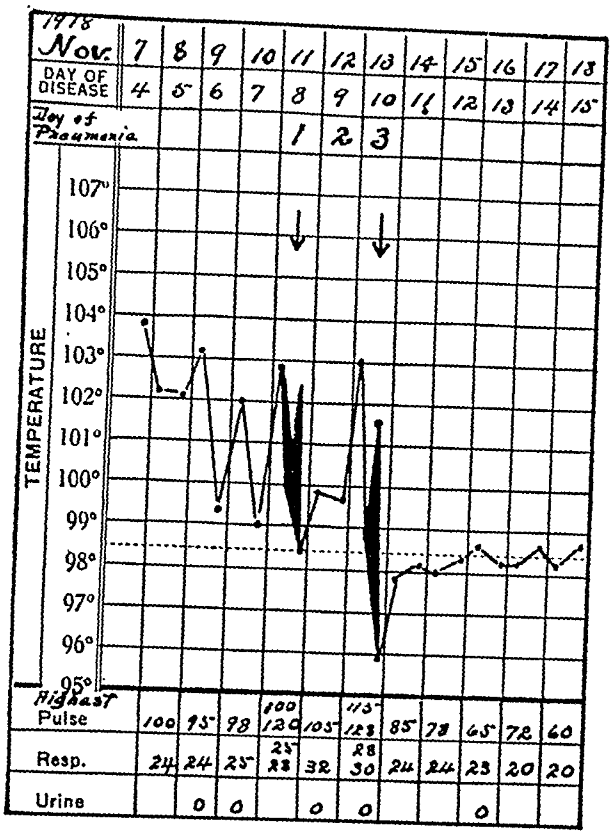

Chart 2.—Temperature, pulse and respiration in Case 2.

TABLE 2.—LEUKOCYTE COUNTS IN CASE 2

	Leukocytes
Nov. 11, 1918, first injection, 500 million typhoid bacilli:	
Control ½ hour before injection	7,500
½ hour after injection	
1 hour after injection	3,000
4 hours after injection	12,000
6 hours after injection	10,000
8 hours after injection	9,000
24 hours after injection	7,800
Oct. 13, 1918, second injection, 500 million typhoid vaccine:	
Control ½ hour before injection	6,000
½ hour after injection	4,500
2 hours after injection	11,000
8 hours after injection	10,500

The following morning at 6 the temperature had again risen to 104.8, and the patient was definitely worse; in fact, he was very ill. At 9 a. m. a half billion dead typhoid bacilli were given intravenously. He reacted just as severely as with the first injection. The temperature reached 106.8 axillary. There was a characteristic fall in the temperature which soon returned to its former height. He grew progressively worse, and died on the second day after the last injection.

The effect of the protein on the pulse and respiration was quite marked, as will be seen from Chart 3.

Urine showed albumin and casts; these did not appear until after the injection. The leukocyte counts are given in Table 3.

Case 4. (4441).—P. K., man, aged 39, entered the contagious hospital, Dec. 16, 1918, with double influenzal pneumonia. He said that he had been ill five days, but we subsequently learned from a friend that he had been ill for two weeks previous to his entrance to the hospital. He was irrational. There was general cyanosis, particularly noticeable on extremities. One billion dead typhoid bacilli were given intravenously the day of entrance at 5 p. m. He reacted typically; the chill began in thirty minutes after the injection and lasted fifty minutes. The temperature before the injection was 103 and reached 105. The following morning the temperature was down to 100. The patient, however, showed no signs of improvement. He became more delirious, more cyanotic, and died at 3:45 a. m., December 18. The urine showed albumin and casts. The leukocytes before the injection were 4,400, one hour later 3,200, and the following morning at 11 a. m., 2,600.

TABLE 3.—LEUKOCYTE COUNTS IN CASE 3

	Leukocytes
12/16/18:	
4:00 p. m. control	8,300
4:45 p. m. 1 billion dead typhoid bacilli	
5:45 p. m.	7,400
6:45 p. m.	8,800
12/17/18:	
11:00 a. m.	15,800

The physical signs, if anything, were more marked after the intravenous injection.

Case 5 (4439).—E. S., woman, aged 20, entered the contagious hospital, Dec. 15, 1918, moribund, with double influenzal pneumonia, the eighth day of the disease and the third day of the pneumonia. There was general cyanosis. Five hundred million dead typhoid bacilli were given intravenously, December 16, at 10:45 a. m. A prompt reaction followed, the temperature reaching 106.8. Before the injection the temperature was 104. The chill began forty-five minutes after the injection and lasted ten minutes. The patient was worse after the reaction. The temperature went down to 100 twelve hours after injection. The cyanosis, however, was progressive from the time the patient entered the hospital. She died the tenth day of her illness. The urine gave a marked reaction for albumin, and there were numerous casts. The leukocytic changes are given in Table 4.

Case 6 (4459).—F. R., man, aged 21, entered the contagious hospital, Dec. 29, 1919, with influenza, the fifth day of the disease. No lung signs could be made out, but other signs pointed to a beginning pneumonia. The following day, December 30, the patient was given 400 million dead typhoid bacilli intravenously at 1 p. m. At this time the temperature was 103.6. There was no reaction for three hours, at which time the patient had a slight chill and the temperature rose to 105 (6 p. m.), after which it gradually declined, as shown in Chart 6. It will be observed that a high temperature was maintained for two days following the injection, but not as high as previous to the injection. This patient was very ill; he became delirious and developed a marked psychosis, for which he is still detained in the psychopathic hospital, one month after the temperature reached normal. We were never able to get any marked

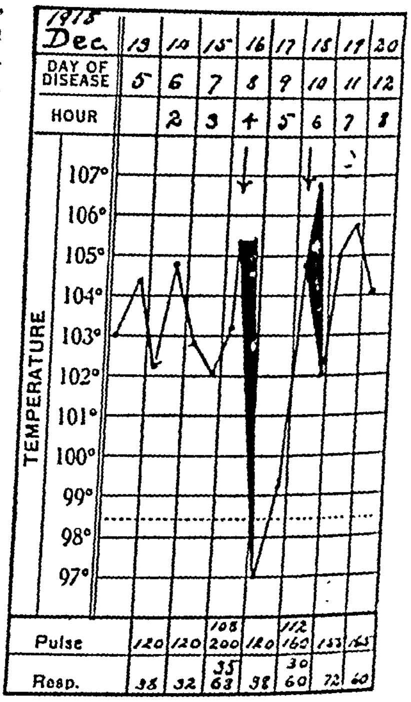

Chart 3.—Temperature, pulse and respiration in Case 3.

physical signs from this patient, for it was almost impossible to examine him. The marked cough, bloody sputum, high fever and other characteristic symptoms led us to regard the case as one of pneumonia.

The urine was negative at all times. The leukocytes were as given in Table 5.

CASE 7 (4460).—Miss N., aged 25, entered the contagious hospital, Dec. 29, 1918, with uncomplicated influenza, the second day of her illness. Pneumonia was detected in the right lower lobe the fifth day in hospital. The chest had been carefully examined each day. Inside of the first twenty-four hours, on the second day, she was given one-half billion dead typhoid bacilli intravenously at 6 p. m. At this time the temperature was 104. She reacted with a chill in forty-five minutes. The chill lasted ten minutes. In two hours the patient's temperature reached its acme, 105.2. The lowest temperature, 102.2, was recorded at midnight and at 6 the following morning. It returned to 104 at 10 a. m., and then dropped by quick lysis to normal, where it remained. The patient made a rapid and good recovery.

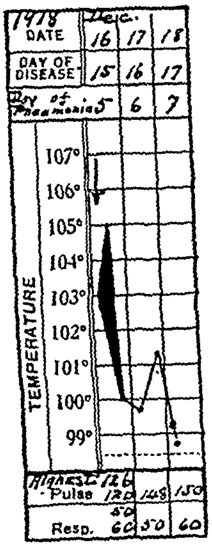

Chart 4.—Temperature, pulse and respiration in Case 4.

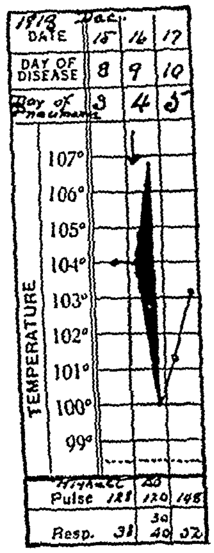

Chart 5.—Temperature, pulse and respiration in Case 5.

TABLE 4.—LEUKOCYTE COUNTS IN CASE 4

	Leukocytes	Polys. %	S. L. %	L. L. %	Trans. %	Eosin. %
12/16/18:						
10:30 a. m. control	5,600	75	18	5	2

11:30 a. m.	5,400					
12:00 a. m.	4,200					
12:30 a. m.	7,700					
1:00 p. m.	8,200	78	17	4	0	1
2:00 p. m.	5,700					
3:00 p. m.	5,400					
4:00 p. m.	5,600					
6:00 p. m.	9,400					
8:00 p. m	12,600					
12/17/18:						
11:00 a. m.	19,800					

Albumin and casts were not found in the urine. The leukocytes are recorded in Table 6.

Before the intravenous injection, the process seemed to be confined to the right lower lobe. The day following the injection, a process was detected in the right middle lobe. We considered the patient's condition very serious, but on January 5, the third day after the injection, she began to show definite signs of improvement. The new process in the right middle lobe seemed to be more distinct.

She was discharged, January 15. At this time there was dulness and increased whispered voice over the lower right base. A roentgenogram taken the following day showed the lungs clear, but there was no question of the forgoing signs on the day of discharge.

CASE 8 (4470).—Mr. M. I. entered the contagious hospital, Jan. 6, 1919, with influenzal pneumonia in the left base, the fourth day of the disease and the first day of the pneumonia. Five hundred million dead typhoid bacilli were given intravenously, January 8, at 12 noon. At 12:47 he reacted with a severe chill, which lasted seventeen minutes when the temperature reached 105.6. Before the injection the temperature was 104.2. The following day the patient felt much better, but the night of January 9 he had severe pain in the left chest anteriorly. The respiration became more rapid; a friction rub was heard in the axilla. These signs of pleurisy continued until January 27. No effusion could be demonstrated at any time. The urine was negative at all times. The leukocytes on entrance were 9,200.

TABLE 5.—LEUKOCYTE COUNTS IN CASE 6

	Leukocytes
12/30/18 control	5,600
12/31/18 (1 p. m.) control	4,600
1 p. m. 400 million dead typhoid bacilli	
1:10 p. m.	2,100
3:00 p. m.	5,500
6:00 p. m.	5,800
8:00 a. m.	4,400

TABLE 6.—LEUKOCYTE COUNTS IN CASE 7

	Leukocytes	Polys. %	Total Lymph. %
Control before injection	3,200	51	49
½ hour after injection	2,500	34	66
1 hour after injection	3,200	30	44
1½ hours after injection	4,000	48	47

Nineteen days after the intravenous injection, roentgenoscopy revealed rather extensive signs of bronchopneumonia. The physical signs—dulness and increased whispered voice—continued over these areas. The patient seemed perfectly well. He was discharged from the hospital, February 1.

CASE 9 (4472).—A. R., man, aged 42, entered the contagious hospital, Jan. 7, 1919, with double influenzal pneumonia, the tenth day of his illness, and evidently so far as we could determine, the seventh day of the pneumonia. He came 9 miles in an ambulance and looked moribund when he entered. He raised considerable bloody sputum. His temperature on entrance was 99.6; at 10 a. m. the temperature had reached 103. At 2:30 p. m. he was given a half billion dead typhoid bacilli intravenously. He reacted forty minutes later with a marked chill, which lasted twenty minutes. The temperature reached 105.4 at this time. At 8 p. m. the temperature was 97.3 six and a half hours after the injection. The patient continued to get worse. The temperature never rose above 100 F. axillary. The patient died at 5:50 p. m., January 8, the second day in the hospital. The urine on entrance was negative. The leukocytes were 1,400; no further counts were made.[2]

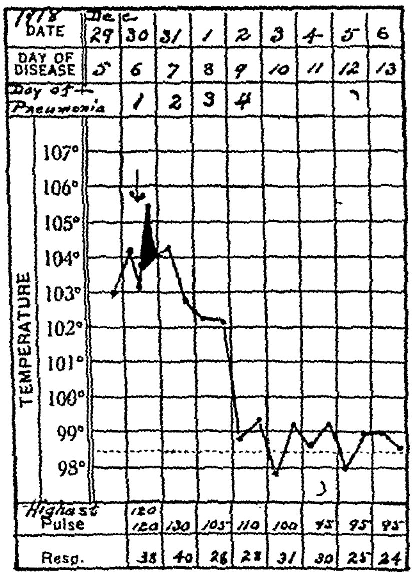

Chart 6.—Temperature, pulse and respiration in Case 6.

---

[2] Since this article was written, we have treated another case of severe influenzal pneumonia by this method, a boy, aged 11, the fifth day of the disease, the second day of the pneumonia, with cyanosis and delirium. Thirty-six hours after the injection, the temperature fell to normal by crisis. There was a pseudocrisis twelve hours after the injection during which the temperature fell from 102.8 to 95.2.

EFFECTS OF THE INJECTIONS

The Effect on the Temperature.—Following the first injection of typhoid protein, there was an abrupt rise of temperature in seven of the nine cases. The rise varied from 1.2 to 4.2 degrees F. The height of the temperature was reached in from half an hour to five hours after the injection. In the two cases that did not react with a rise of temperature (Cases 2 and 3) there was an increase in temperature, however, following the second injection given from forty to forty-eight hours after the first injection. The rise was 2.8 and 3 degrees, respectively.

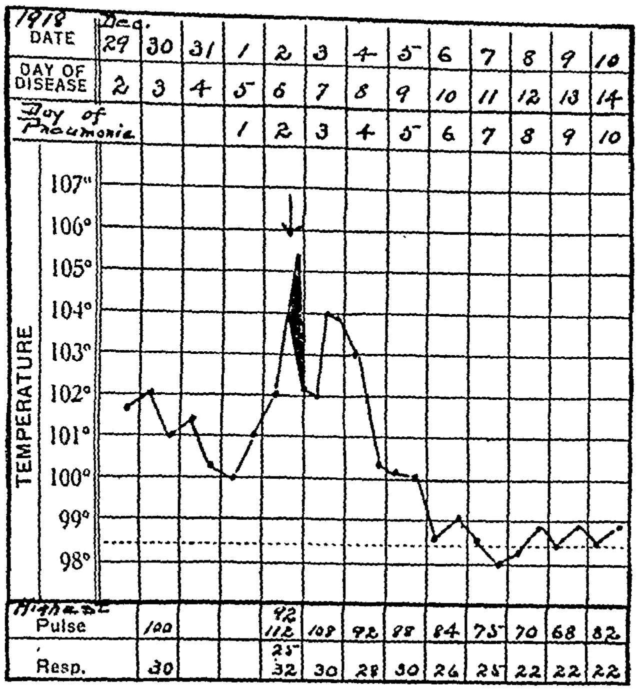

Chart 7.—Temperature, pulse and respiration in Case 7.

The temperature was reduced below the height reached just previous to the injection in eight cases. This reduction occurred from five hours to sixteen hours after the injection, usually within eight hours. The reduction varied from 0.4 to 8.6 degrees. The induced temperature fall was usually more than 3 degrees. In Case 6, in which Table 7 records no fall in temperature following the injection, there was a definite decrease, but this did not occur until the third day. We attribute this to a prolonged protein reaction, such as was observed by Cowie and Calhoun[1] in Case 8 of their series. As there might be a doubt concerning this, we have not included it in the graphic chart or in Table 7. From these observations we conclude that an intravenous injection of typhoid protein in influenzal pneumonia causes a typical clinical protein reaction, which is followed by a marked decrease in the temperature.

The Effect on the Pulse.—Following the injection of typhoid protein, in six of the nine cases there was a rise in the pulse rate. The rise varied from 8 to 50 beats a minute, excepting in Case 3, in which the increase for the first injection was 48, and for the second, 92. In three cases there was no effect on the pulse rate. In those cases in which an increase occurred, it usually amounted to 20 beats a minute. An interesting observation is that the highest pulse was not reached until an hour and sometimes two hours after the injection. A dangerous pulse rate was observed in only one case, referred to above, but even in this case there was no permanent effect on the pulse.

We concluded that an intravenous injection of typhoid protein causes an increase of about 20 beats a minute in the pulse rate in from one to two hours after the injection. This increase is not permanent. We were unable to demonstrate in any way that the myocardium had been injured by the injection.

The Effect on the Respiration.—Following the injection of typhoid protein, the respiration rate was increased in seven of the nine cases. The increase varied from 7 to 15 respirations in all but one case (Case 3). After the first injection of one billion dead typhoid bacilli in this case the increase in the respiratory rate was 33. After the second injection of one-half billion, given two days later, the increase was practically the same, 30. The effect on the respiration, as on the pulse, was not a permanent one.

The Effect on the Physical Signs.—Almost invariably the physical signs were more marked following the injection. This was just as true of those who lived as of those who died. In a large percentage of our influenzal pneumonias the physical signs persisted a long time after the patient was, apparently, well, and, as the same findings occurred in our pneumonia patients treated with typhoid protein, we feel justified in saying that the injection had no effect on the physical signs. We certainly could not demonstrate that the signs were in any way decreased.

The Effect on the Course of the Disease.—In the patients that lived, the symptoms of the disease were terminated by crises in four cases, two on the first day after the injection (Cases 1 and 2), one on the second day (Case 7), and one on the third day (Case 6). In Case 2 the crisis followed the second injection. In one case the symptoms terminated by lysis. In the patients that died, no effect was observed in two instances. There was a decrease of temperature in Case 8. In Case 3 in addition to the decreased temperature, definite signs of general improvement occurred for twenty-four hours following the first injection. In each one of these cases we felt that the course of the disease would have been terminated by death had not the foreign protein been given.

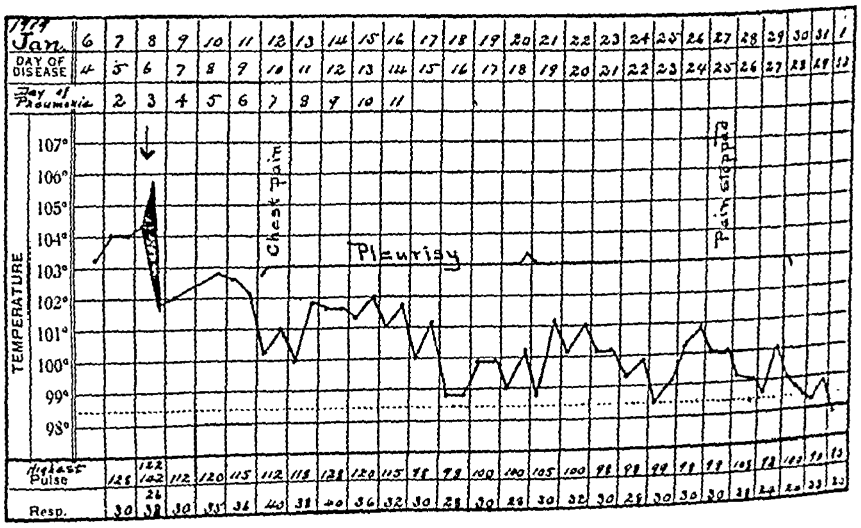

Chart 8.—Temperature, pulse and respiration in Case 8.

An analysis of our charts shows that no improvement was obtained in those patients who received injections after the third day of the pneumonia (Cases 3, 4, 5 and 9), while those who received the injection not later than the third day recovered.

The Effect on the Leukocytes.—It was not possible for us to carry on a systematic examination of the progressive leukocyte changes in the blood following the injection of the typhoid protein, as has been done by Cowie and Calhoun in other infections. We have enough data to conclude that a fairly typical leukocyte response was obtained in the majority of the cases. The response was usually only of moderate degree. In two patients, both of whom died, there was a marked increase in the leukocytes on the day following the injection, amounting to 8,000 in one case and 14,000 in the other. These may have been prolonged reactions, such as were observed by Cowie and Calhoun, in which a very high leukocytosis was maintained for thirty-six hours after the injection.

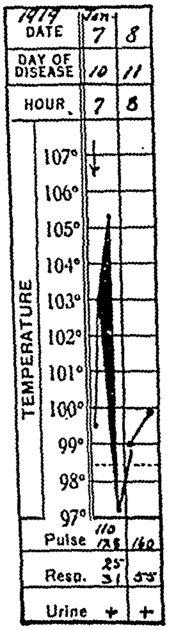

Chart 9.—Temperature, pulse and respiration in Case 9.

The typhoid protein, as a rule, induced no marked or permanent change in the number of the leukocytes.

The Effect on the Urine.—Urine examinations were done before and after the injections in all but one case (Case 9). In two of these, albumin and casts were found on the day following the injection when they had not been present before. One of these patients died. In a third case, albumin and casts appeared on the second day after the injection was given, the day on which the patient died. In the other cases there was no change in the urinary findings.

DOSAGE

The clinical reaction is more marked after a billion dose of dead typhoid bacilli, but no more beneficial effect was produced in the blood, subjective symptoms, or on the course of the disease than was noted with the half-billion dose. Our experience from observation of the reactions inclines us to recommend the half-billion dose. It may be a significant fact that in the two cases in which a billion dose was given, both patients died (Table 7).

Care should be taken that at least a day intervenes if more than one dose is given.

CONCLUSIONS

1. An intravenous injection of typhoid protein in influenzal pneumonia is a safe procedure within limitations.

2. Intravenous injection of typhoid protein is indicated only in the beginning stage of the pneumonia, so far as we are able to determine from our limited number of cases.

3. The use of this method of treatment is contraindicated (*a*) in cases of influenzal pneumonia advanced beyond the third day of the disease, or (*b*) when there is undoubted evidence of advanced myocardial insufficiency or acute endocarditis.

4. No more than 500 million dead typhoid bacilli should be given at one injection. For well known reasons, at least forty-eight hours should intervene before another injection is given.

5. The immediate effect of the foreign protein is the development of a typical protein paroxysm, which is followed by a marked decrease in the temperature and a definite improvement in the subjective symptoms, both of which are usually permanent.

6. Following the injection of the typhoid protein, there is a characteristic leukocytic movement. The leukocyte increase in the cases studied is only of moderate degree. There is no permanent improvement in the leukopenia or downward tendency of the leukocytes.

7. The effect on the pulse, respiration, physical signs and urine findings is practically negligible.

8. An intravenous injection of typhoid protein may bring about a termination of the acute symptoms of the disease in from one to three days.

TABLE 7.—RESULTS OF PROTEIN INJECTIONS

					Protein Reaction

Results from Children's Year Campaign.—The Children's Bureau in a bulletin just issued gives a preliminary accounting of the success of the Children's Year Campaign, begun April 6, 1918, to save 100,000 babies. The reports are not all in yet, but among the first activities was the weighing and measuring of the babies. Of 7,000,000 cards distributed, 1,619,283 have been returned to the bureau, where the information will be tabulated. Twenty-four states have employed new public health nurses, 137 having been employed in ten of the states. One hundred and thirty-four children's health centers were established during the year in fifteen states, with an uncertain number of centers established in nine other states. Forty-three states are conducting back to school and stay in school drives, and a number of communities have established scholarship funds to enable the children of needy parents to continue their education after they reach the legal working age. At least one scholar[illegible] for each of the 281,000 schools in [illegible] ry is the aim [illegible] bureau is planning a confer[illegible] foreign child w[illegible] experts.

A STUDY OF ACUTE MASTOIDITIS AT FORT RILEY, KANSAS

J. R. SCOTT, M.D. (NEWTON, KAN.)

AND

E. L. POSEY, M.D. (MAGEE, MISS.)
Lieutenant, M. C., U. S. Army

FORT RILEY, KAN.

Acute mastoiditis as a contributing cause to the ineffective list in army camps has assumed great importance. This is due to (1) the large number of cases; (2) the long convalescence (seven weeks is the average), and (3) the tendency toward imaginary if not real weakness of the individual for several weeks, or even months, following his return to duty. The mastoid wards in the departments of head surgery require more attention from the staff officers, nurses and corpsmen than all other wards. The seriousness of the disease in itself demands constant attention to the many details that are associated with a critical illness in the army. Only those who have been in the service can appreciate the importance of this statement.

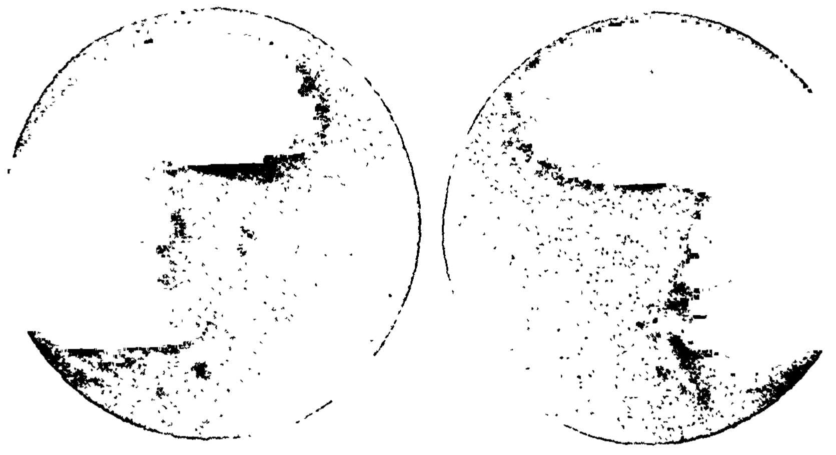

Fig. 1 (Type 1).—Absence of cells in mastoid; double otitis media with tenderness of mastoid area; no operation.

Since each base hospital connected with the various cantonments had mastoid cases in larger numbers than the civil hospitals, and the opportunity for the study of individual cases was favorable, a better knowledge of this disease was the natural result. The unlimited laboratory and roentgenographic facilities, the occurrence during epidemics of the exciting causes of mastoiditis, bringing many cases of a particular type under observation at one time, and finally the opportunity to operate when it was deemed necessary, afforded an unusual opportunity to study this disease.

The last has not been heard of the recent epidemic of influenzal pneumonia, and otitis media will be encountered for at least another year, owing to the hangover virus which took such a terrible toll. Elsewhere a report on the epidemic at Camp Funston has been reported.[1] In it can be found details of interest in connection with this article.

ETIOLOGY

The prevalence of mastoiditis in our army camps is not surprising when analyzed from the etiologic standpoint. In ordinary peace times, mastoiditis is rather infrequent. But our army was suddenly increased many times. Intensive training became the order of the day. Men were suddenly taken from all walks of life and were housed in barracks. Work could not stop because of changes in the weather. Slight indisposition of the individual soldier was not sufficient to permit a luxurious room and a rest from work for a day or a week. The men did not become hardened soldiers in a day. The camp conditions, while for the most part conducive to health and physical development, were for an occasional one here and there just the opposite. An epidemic of mumps and measles, isolated cases of scarlet fever, diphtheria, meningitis, and almost universal tonsillitis, all aided in the development of a rather peculiar condition which was responsible in the end for the increased incidence of two army diseases of importance, pneumonia and mastoiditis.

LOCALITY INFECTION

By the term "locality infection" is meant the occurrence in a locality or army post of a certain organism which is found to predominate either singly or combined, in infections occurring in that particular locality or army post. At one camp, for instance, the hemolytic streptococcus may be the organism found in the tonsil crypts, in pneumonia, in mastoiditis, or other diseases, while in another camp the pneumococcus or *Streptococcus viridans* may be the prevailing organism. Any one of these organisms may become virulent for a certain period and then apparently becomes of little consequence. However, when an epidemic of tonsillitis, measles, scarlet fever or influenza occurs, then the particular organism for a certain locality suddenly assumes the rôle of secondary invader and becomes the predominating factor in complications. That the temporary home for this "locality-infection" organism is in the tonsil crypt is undoubtedly true, though it is found at times in the accessory nasal sinuses.

The spasmodic appearance of a number of cases of acute mastoiditis is not surprising when one considers the foregoing factors as noted in cantonments. This is illustrated in Table 1. During January, February, March, April and May of 1918, the hemolytic streptococcus was the locality infection at Camp Funston. The number of pneumonias and mastoiditis cases (requiring mastoidectomies) as shown in Table 1 was so great that one could speak of it as an epidemic. The organism that predominated in both series of cases was the hemolytic streptococcus, which occurred in 28.2 per cent. of all pneumonias and in 76 per cent.

TABLE 1.—INCIDENCE OF PNEUMONIAS AND MASTOIDECTOMIES AT BASE HOSPITAL, FORT RILEY, IN EARLY MONTHS OF 1918

1918	No. of Pneumonias	No. of Mastoidectomies

P.: A Clinical Study of Pneumonia Based on Eight Hundred and Seventy-One Cases, Arch. Int. Med. **22**: 409 (Oct.) 1918.

of the mastoids (cultures from the mastoid cells at time of operation). The term "streptococcus epidemic," therefore, is a better term.

In the recent epidemic of influenza in the same hospital, tissue cultures at necropsy showed the predominating organism again to be the hemolytic streptococcus. It was present singly or combined in 41.1 per cent. of all tissue cultures including the lung, pleural fluid, heart-blood, spleen, nasal sinuses, mastoids and spinal fluid. Blood stream invasion occurred late in this series of cases.[1]

Following the epidemic of influenza, cases of measles began to appear in large numbers, and again pneumonias and mastoiditis. The primary diseases lowered the resistance of the patients, and blood stream invasion by the prevalent organism, the hemolytic streptococcus, again occurred with the resulting complications. In a series of fifty mastoiditis cases beginning in October, 1918, twenty-two cases were complications of measles. The hemolytic streptococcus was found in 46 per cent. of all cases, as shown in Table 2.

From the foregoing statements one must conclude that the occurrence of mastoiditis as seen in army cantonments depends on the surroundings of the individual and the presence of a virulent organism, such as the streptococcus or pneumococcus; further, that the invasion of the mastoid occurs directly from the nasopharynx or the blood stream.

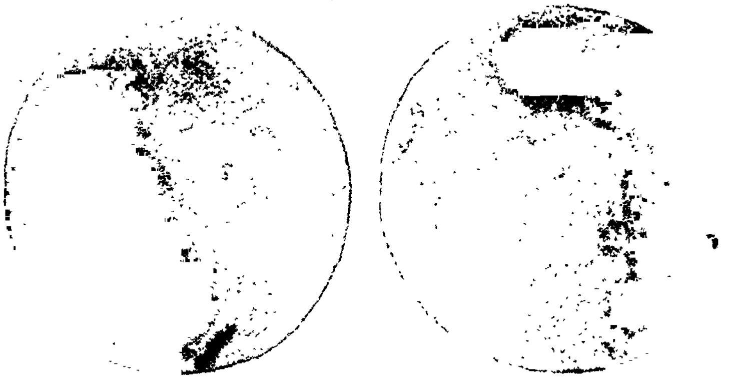

Fig. 2 (Type 1).—Presence of a few cells in posterior tip of right mastoid; double otitis media with tenderness of mastoid area.

PATHOLOGY

The importance of roentgenoscopy in the study of individual mastoid infections cannot be overestimated. The desultory taking of roentgenograms means absolutely nothing. The technic must be perfected with each machine and for each step in the production of a roentgenogram. The clinician must study the finished plate with the roentgenologist. One plate is not always sufficient. Both mastoids must be shown on one plate to afford means of comparison. When a new make of plates is used, the technic must be revised. One person should take all the exposures of a single mastoid case. If these rules are observed, the opening statement will prove true.

VARIATIONS

That all mastoids are similar is true, but a certain variation in the structure of the bone will be noticed after different roentgenograms have been studied. In general the cases fall into three types: (1) a rudimentary type, with a square or rectangular shape, having practically no mastoid cells; (2) a type presenting a more extensive area of large cells situated entirely behind and below the antrum, and (3) a type with a much larger area of many small cells extending into the zygoma, far back and down to the tip. Type 1 is never serious because there are no cells to become infected. The otitis media will eventually subside without operation. Types 2 and 3 must be carefully watched. In subacute cases the first roentgenogram may show a delicate haze over the entire region, the antrum being especially hazy, with areas here and there of denser opacity where the cell walls are thicker and the pus pocketed.

TABLE 2.—INCIDENCE OF ACCOMPANYING DISEASES AND BACTERIOLOGIC SHOWINGS IN FIFTY MASTOIDECTOMIES OPERATED ON BETWEEN OCT. 1 AND DEC. 31, 1918

No culture	10	20
Miscellaneous	3	6
Total	50	

Bone necrosis will manifest itself by a confluence of the cellular spaces and a denser haziness in the region of the antrum and the tip. This can be detected only by comparison with the roentgenogram of the opposite or normal side. This comparison is of great advantage especially when the normal roentgenogram is on the same plate as the roentgenogram of the side affected. It is relatively true that the two mastoids correspond in size and structure in each individual case. Having the normal mastoid to use for comparison gives a clue to the size and shape of the mastoid, and to the degree of bone necrosis. A postoperative roentgenogram will frequently prove of value in cases that show a tendency toward sluggishness in healing.

Influenza cases develop frequent mastoid involvement without bone necrosis. On the other hand, measles-mastoiditis cases are very prone to develop bone necrosis of the fulminating type. The first necrosis occurs along the chain of cells leading from the antrum to the tip. These cells are deeply situated and have a dependent position as the patient rests in bed. The cell walls are delicate. The course of the sinus is changed at this place and causes an anatomic arrangement of these cells that is not conducive to easy drainage. Blocking at this point results in necrosis both in the tip and in this region. In the roentgenogram they are usually overshadowed by the overhanging posterior wall. When the angle is such as to reveal them they are seen between the dense wall surrounding the internal meatus and the white line just external to this which is the thickened inner table of the sinus as it courses downward to the bulb. When this line blends with the dense shadow of the wall of the meatus, one must study closely for necrosis in the tip cells. The technic, the classification of mastoids into types corresponding to the clinical types, the anatomic variations and the resulting shadow have been determined in an extensive study of this phase of the subject at the army hospital at Fort Riley with Captain Cummins and Lieutenant Kirklin of the roentgenologic department.

SYMPTOMATOLOGY

Under etiology, the subject of the onset of mastoiditis was discussed. This is of importance in further consideration of the symptomatology. Three distinct types or modes of onset are recognized:

1. Cases in which the otitis media symptoms predominate and the mastoid involvement is slight. The roentgenograms of Type 1 (Figs. 1 and 2) illustrate the anatomic features of this series of cases. The drum is bulging on inspection, and the discharge is profuse following rupture or paracentesis. These cases rupture spontaneously shortly after onset. The temperature is higher in this class than in any other. Eventually healing takes place, but not until numerous reopenings have been made in the drum.

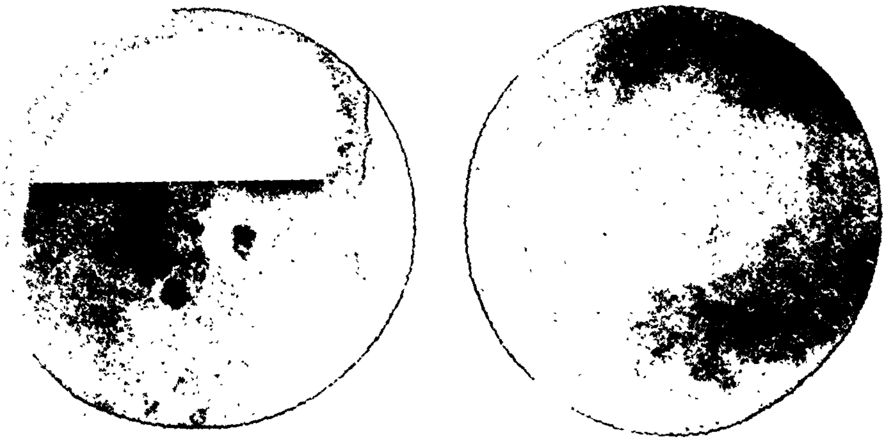

Fig. 3 (Type 2).—Acute mastoiditis (right); no necrosis of cells except between sinus and posterior wall, where a gutter leads from antrum to tip; verified at operation; case following measles; no culture.

2. Cases in which otitis media and mastoiditis appear to develop at one and the same time (Figs. 3 and 4). These cases are serious from the first. One must watch closely for necrosis. There may be no clinical symptoms other than a severe pain which is relieved on puncture of the drum. Suddenly the discharge stops and the case seems about to clear up, then an elevation of temperature is noticed — 99 F. in the afternoon, perhaps. From the beginning the roentgenograms show haziness and no tendency to clear. When operation is performed the entire cell structure is found to be necrotic. The absence of tenderness is due usually to the dense, hard, thick, outer table, but in some cases it may be elicited by deep pressure over the posterior aspect of the tip.

3. Cases occurring in systemic infections. The mastoid is invaded and becomes necrotic before any discomfort is noted by the patient. This seems to be a rash statement, yet operations have been performed in cases which presented this condition. The first symptom was a sudden, terrific headache. The drum appeared bulging but deep red. No pus escaped on puncture, and the opening closed rapidly. Roentgenograms in these cases showed extensive tip cell necrosis. On no basis other than blood stream invasion of the mastoid can this type of mastoiditis be explained.

BLOOD COUNTS AND CULTURES

The number of white cells in a series of fifty mastoid cases of all types averaged 13,300. That the white count depends on conditions other than the mastoiditis is evident. Too much emphasis cannot be placed on this test. Blood cultures are important when positive for the organism; therefore in cases of suspected system invasion, cultures should be obtained if possible.

HEADACHE

An important symptom is the headache occurring at any time during a mastoiditis. Headache suggests meningeal irritation. It is not always true that it points to so grave a complication, but whenever headache is constant one must consider the possibility at least of dural irritation. It is one of the first symptoms of meningitis. It is the one clinical symptom that, at no time during a mastoiditis, should ever be treated lightly.

MANAGEMENT OF INDIVIDUAL CASES

To class all mastoiditis cases in one group, and to operate only when the clinical symptoms are pronounced, is the tendency of most surgeons. The result of this procedure is uncertain. To advocate early operation in otitis media cases presenting mastoid tenderness is even less advisable. The ideal method would be to strike a happy medium — an impossible procedure. If one awaits the appearance of clinical symptoms of mastoiditis warranting operation, many cases will be so far advanced that destruction of bone, unsightly scars, and even death may result. If one operates too early, before bone necrosis occurs and resistance of the body to the infection is present, one submits the patient to unnecessary risk, the possibility of secondary operation because of bone infection and because of rapid absorption following operation.

There can be no set rule, for some cases require early and others late operation, depending on the circumstances connected with the individual case.

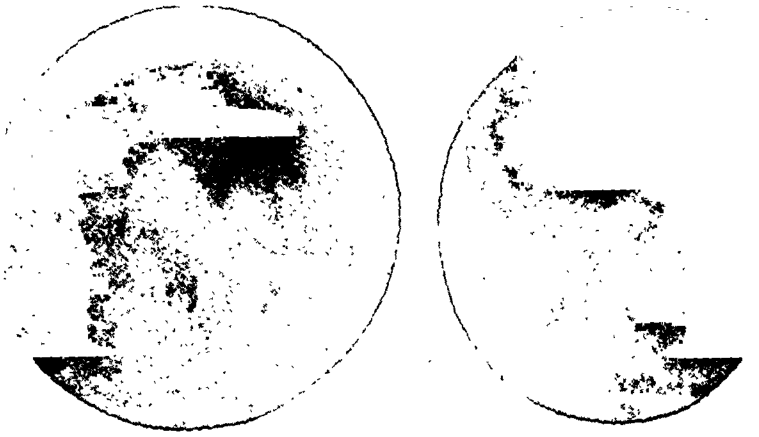

Fig. 4 (Type 2).—Necrosis of all posterior cells of right mastoid; outline of cells gone; verified at operation; hemolytic streptococcus.

The type of mastoiditis depends on two factors: (1) the anatomic arrangement of the mastoid cells, and (2) the character of the infection.

1. The first point was discussed under roentgenoscopy. Types 1, 2 and 3 are general types. Intermediate or overlapping cases are frequent, and so the types must be considered as relative rather than absolute—merely as a general rule for classification. An exception to this rule is found in those cases in which one side is normal, while the other side has a chronic otitis media resulting in sclerosis of the mastoid cells. These cases, however, are easily identified by taking a careful history.

2. The second point, the character of the infection, must be the determining factor in the majority of cases. But the factors to be considered are the condition of the patient, the organism present, and the degree of invasion. A patient who has had an acute infectious disease, such as measles or scarlet fever, or a prolonged illness, such as pneumonia, will develop suddenly bone necrosis. This constitutes the fulminating type of mastoiditis. Strong, robust individuals developing an otitis media following a cold or tonsillitis withstand a severe infection under ordinary circumstances. The streptococcus and the pneumonia groups are by far the most serious organisms to deal with. The degree of invasion depends on the presence or absence of bone necrosis, and is the most difficult of all the problems to solve.

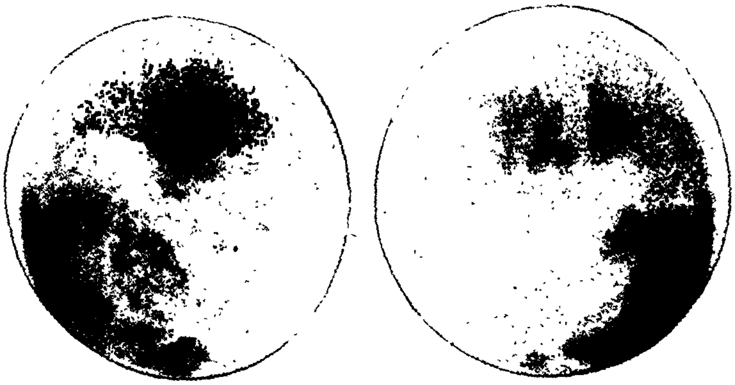

Fig. 5 (Type 3).—Influenzal mastoiditis; right mastoid shows delicate haze; no operation.

In a certain percentage of cases one may determine its presence by clinical symptoms—sudden appearance of the classical picture of mastoiditis. The problem is easily solved in these cases. But to wait for this classical picture is not always necessary, nor always safe. Many cases also will apparently subside and the patient will be discharged, only to have an irritable mastoid which will flare up on the first "bad cold." If sclerosis occurs, these patients later develop a chronic otitis media and become a nuisance both to themselves and to their associates.

An extensive study of many cases of acute mastoiditis has convinced us that the problem of bone necrosis can be solved by means of the roentgenogram, and when present, operative interference is imperative. The only exception to this rule is when blood stream invasion is known to have existed prior to the time of bone necrosis. In these cases one is justified in postponing the operation until the systemic infection subsides. This cannot always be done, and in such cases the prognosis is most grave.

THE OPERATION

Any operation that has for its subject the complete removal of the mastoid cells, drainage of the antrum, and the least possible trauma, is sufficient for the relief of mastoiditis. This means that sufficient bone must be removed to obtain access to all necrotic areas, even though it requires exposure of the sinus or dura.

AFTER-CARE

The quicker one obtains complete closure of the wound, the better for the patient. This does not mean permitting the cavity to fill with mushroom granulations. To obtain firm, clean granulations the use of chloramin-T paste is advised. General care of the patient should include rest, sufficient exercise, nourishing food, alkaline drinks, and repeated assurance that no ill effects will follow from the operation.

COMPLICATIONS

Two stages in the course of a mastoiditis case require one's attention, the diagnosis of bone necrosis and the diagnosis of complications. Many careful observers have spent hours in worry over whether to operate or to wait, only to have the case clear up or fulminate before decision has been reached. Who has not diagnosed a case as meningitis or sinus thrombosis only to find that a dose of calomel relieves all symptoms over night?

Facial Paralysis.—One does not have to worry over the diagnosis of a facial paralysis, and yet it is a great comfort to both the operator and the patient to state that it is only a paresis. One should never attempt to deceive oneself in regard to the cause of a facial accident. If the chisel slips, if the ridge is broken, if the curet is too sharp and cuts too deep and the face twitches in spasm, the result usually can be foretold and one need not hope just for a paresis. If, however, the staring eye, the smooth face, and the lifeless cheek appear on the second, third or fourth day, one may predict a paresis and assume a good prognosis. Massage, frequent dressings, and gradual exercise aid in recovery.

Sinus Thrombosis.—The classical symptoms of sinus thrombosis are too well known for much further discussion. In the absence of a fall in temperature or a sudden rise, the appearance of a swollen joint is not indicative of sinus trouble. Blood stream invasion by the organism may have preceded the onset of the mastoiditis and caused many so-called complications to mastoiditis, among them, arthritis.

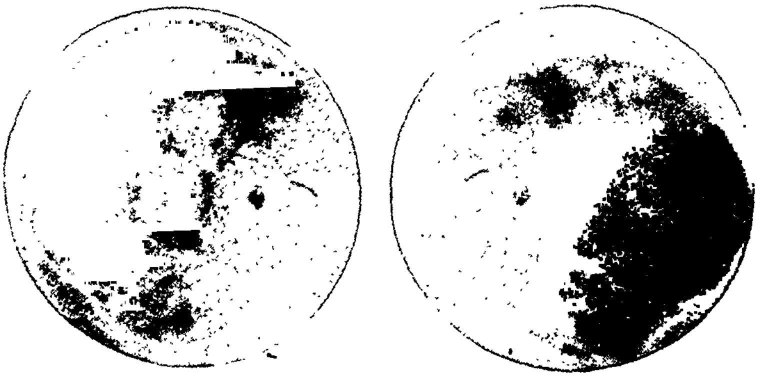

Fig. 6 (Type 3).—Influenza; right mastoid shows slight haze; no operation; white shadows external to bony canal show edge of lateral sinus.

Parotitis.—This is a complication in mastoiditis that occurs frequently. It is usually caused by too much or too forceful attention to the canal. The infective agent, usually *Streptococcus viridans,* gains access to the parotid region by way of the openings in the cartilaginous canal. Prompt incision with a Graefe knife at the point of entrance (seen in the canal) will relieve the condition. Facial paresis may develop from this complication.

Erysipelas.—This may develop especially following streptococcus infection. It is severe on the patient but never proves fatal. Treatment aids in relieving the suffering, but not in hastening the recovery.

MENINGITIS

The most serious and heart-breaking condition that may present itself is the headache, stiff neck, malaise, death from meningitis, the most dreaded of all complications and the least understood. In a series of necropsies in forty-one influenzal pneumonia cases, reported elsewhere, some interesting data were obtained. Later necropsies in three cases, diagnosed as meningitis occurring during mastoiditis convalescence, added to the knowledge obtained from the previous necropsies. From the forty-one necropsies it was found that meningitis was a frequent complication in pneumonia of the streptococcus and pneumococcus types; that in cases with and without mastoid involvement, the blood, pleural fluid, and spinal fluid gave positive cultures, especially when *Streptococcus hemolyticus* was the invading organism; and that edema of the brain, congestion of the cerebral vessels, and dilatation of the ventricles were associated with the pneumonia. This led to a more careful search for blood stream invasion in measles or pneumonia mastoiditis cases, especially when *Streptococcus hemolyticus* was the organism suspected. In three cases of measles mastoiditis resulting fatally, necropsy disclosed in the first a cerebellar abscess, in the second a diffuse meningitis (plastic) with frontal lobe abscess on the side of operation, and in the third a similar picture with the abscess of the frontal lobe on the opposite side. Cultures taken at necropsy showed *Streptococcus hemolyticus* in all tissues in each case. In none of these cases could any connection be found between the area of the operation and the meningitis.

The conclusion one must draw is that meningitis is not due to the mastoiditis but to the conditions present at the time of operation. For this reason a careful study of each case is essential: By gradual classification of the mode of onset, the type of mastoid structure, the character of the infection, and the degree of necrosis, together with a study of the blood invasion, a certain number of cases will be found that one may term dangerous. These cases are few in number but are usually fatal. The onset is slow, since they follow measles or pneumonia; they occur in mastoid Type 2; the source of infection is usually *Streptococcus hemolyticus;* bone necrosis occurs early and is extensive; the blood stream may show the presence of the organism; the brain may be congested, the cerebral vessels engorged and the ventricles dilated. Thus the groundwork has been laid for a meningitis. It requires only the trauma of the chisel or the anesthetic to complete the work. These are the problems that confront the surgeon.

CONCLUSIONS

1. The prevalence of mastoiditis in army cantonments is due to a number of reasons. The new surroundings of the recruit play some part in it and constitute a predisposing cause. The presence of a locality infection and epidemics of acute contagious diseases are the chief factors.

2. Invasion of the middle ear and mastoid cells may occur by extension from the nasopharynx or directly from the blood stream.

3. The anatomic structure of the mastoid body is of importance in the prognosis of each case. Roentgenoscopy will alone determine the character of the cell arrangement.

4. For clinical purposes, mastoids may be classified as Type 1 (Figs. 1 and 2) rudimentary or cell-free mastoids; Type 2 (Figs. 3 and 4) in which the cells are of the pneumatic variety and are found only below a horizontal line drawn through the upper margin of the meatal ring, as shown in the roentgenogram, and Type 3 (Figs. 5 and 6), showing small cells extending forward in the zygomatic region, high posterior cells, and many delicate cells in the tip. Type 1 mastoids rarely if ever develop acute mastoiditis, but the otitis media is the most marked of all types. In this class of cases, operation reveals the sinus clinging closely to the posterior wall. Type 2 is the most serious of the three and almost always requires operation. The cells of the tip and posteriorly are of the pneumatic type. The drainage is poor, and necrosis occurs early and may be fulminating in character. Type 3 is characterized clinically by an early tenderness over the entire mastoid area which subsides on the application of hot compresses. They drain easily and seldom require operation. Mastoiditis is associated with otitis media in only Types 2 and 3. As Type 1 may be due to faulty development or to an otitis media in early childhood, a large number of mastoids of this type are found. This accounts for many severe otitis media cases that show no clinical evidence of mastoiditis, although a high temperature and even chills may occur.

5. Bone necrosis is the one important sign in mastoiditis which must be carefully sought. Its presence makes operation imperative. It occurs in Type 2 with little or no clinical manifestation until the tip and posterior cells become necrotic. Fulminating signs then appear. When operation is indicated, it should be thorough.

6. Chloramin-T paste is a good dressing to use in the after-care of patients.

7. Blood stream invasion may cause the mastoiditis, and with it involvement of structures within the cranium. In such cases, meningitis may be hastened by a prolonged operation. So-called otitis meningitis is a very rare complication. Septic joints, pericarditis, meningitis, or abscess of the brain due to the primary invasion may develop, early or late, in the course of the illness. Sinus thrombosis is easily differentiated by the presence of the chill and the rapid rise and fall of temperature.

Health in Cumberland.—In the annual report number of the Cumberland (Maryland) *Health Bulletin* (April, 1919), Max J. Colton, health officer, in an address to the "Veterans of the World War," takes them into the health organization of Cumberland by appointing them deputies to assist in carrying out at home the principles of hygiene which they were taught in the Army. He says: "You want yourselves and your families protected from as much disease as possible," which "is no more than is due every citizen of a community. You yourself can help to bring the protection home. You can urge the members of your family to be vaccinated and inoculated, you can become the sanitary inspector of your home, see that the privy vault is flytight, that the garbage can is kept covered. If some one you know has a venereal disease, see that he secures treatment from a reputable physician, or from the clinic which is being operated in the city hall, where treatment can be secured free of charge, that the quarantine regulations be observed wherever a communicable disease exists, and, in a word, appoint yourself a guardian of the community." Cumberland with a population of 27,298 in 1918 had 736 births, an increase of eighty-two over the previous year, and the largest number of births in the history of the city. This gave a birth rate of 26.96 per thousand of population. There were 114 stillbirths. The total number of deaths not including the influenza epidemic, accurate figures for which are not yet available, was 578, a rate of 21.17 per thousand.

DUODENECTOMY

A NEW METHOD *

JAMES J. MOORHEAD, M.D.
AND
HERBERT E. LANDES, A.B.
CHICAGO

During the course of some work on the nature of the toxemia in intestinal obstruction[1]—in which removal of varying lengths of the jejunum and the ileum produced no other effect than an easily explained nutritional disturbance—it was decided to take up later this problem: Is the duodenum one of the so-called vital organs, and if so, what is the nature of its vital function? Obviously, a successful duodenectomy would answer this question in part.

The duodenum—discovered and named by Herophilus—developed embryologically from the foregut, with its outbuds, the liver and the pancreas, is a most important part of the digestive system.

Anatomically, the duodenum in the dog, unlike that in man, is of the fetal type—mobile, and almost completely covered with peritoneum. Intimately connected to its medial border is the body of the pancreas. Its blood supply comes chiefly from the pancreaticoduodenal artery. The nerve supply is composed of extrinsic nerves of parasympathetic origin carried in the vagi, and nerves of sympathetic origin coursing in the splanchnics. The intrinsic nerves are the plexuses of Auerbach and Meissner. Compared with the remaining portion of the small intestine, the wall of the duodenum is thicker and more muscular and its lumen larger. The histologic structure of the duodenum of the dog, like that of man, is characterized by the presence of the large tubuloracemose glands of Brunner which occupy the submucosa.

Physiologically, the duodenum is the recipient of the chyme, the bile and the pancreatic juice. From its mucous membrane is secreted an enzyme, enterokinase, on which the pancreatic juice is dependent for its activation. Like the remainder of the intestine, it is an organ of absorption, secretion and excretion.

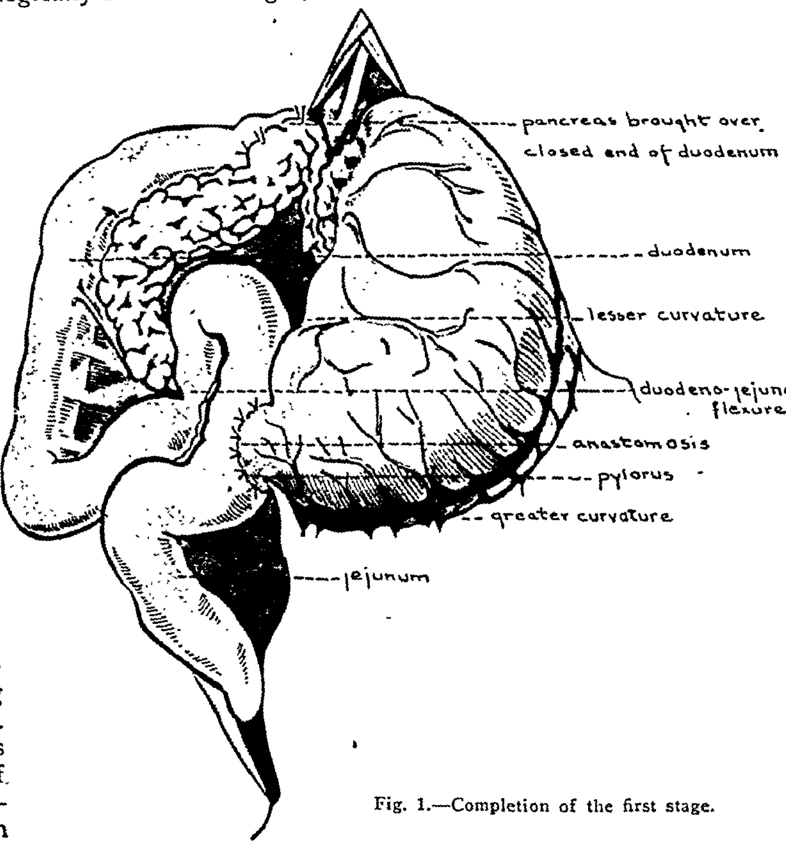

Fig. 1.—Completion of the first stage.

PREVIOUS WORK

Pflüger[2] concluded from work on the frog that diabetes followed injury to the nervous connections between the pancreas and the duodenum in attempts to extirpate the latter. Subsequent work on the duodenum of the dog reported in the foreign literature by Minkowski,[3] Rosenberg,[4] Ehrmann,[5] Lauwens[6] and Bickel[7] rendered this theory untenable.

Minkowski removed the splenic portion of the pancreas and anastomosed the jejunum to the posterior surface of the stomach. Subsequently the common bile duct and the pancreatic duct were ligated and divided and the gallbladder anastomosed to the jejunum. The pylorus was cut through and both ends closed. The duodenum, including the pancreas, except the uncinate process, was extirpated. One dog lived three weeks without becoming diabetic. This was the first successful duodenectomy.

Rosenberg, Ehrmann, Lauwens and Bickel report methods varying somewhat from the preceding, but having the same end in view.

The American investigators Matthews,[8] C. A. and L. R. Dragstedt, McClintock and Chase,[9] and Grey[10] have worked on the problem of duodenectomy.

Matthews concluded from his experiments that extirpation of the duodenum was incompatible with life longer than seventy-two hours.

C. A. and L. R. Dragstedt, McClintock and Chase of Iowa City had one dog live three months following duodenectomy. In this animal the bile was drained to the outside by a gallbladder fistula, and the body of the pancreas removed.

Grey of Baltimore was successful in one instance in which he preserved the bile by cholecystenterostomy and the pancreatic juice by transplantation of the pancreatic duct into the jejunum. The dog lived eight and one-half months.

Only a few attempts at such an operation were necessary to convince us that extirpation of the duodenum was attended with many difficulties not encountered in resection of other portions of the alimentary tract. Such difficulties gave rise probably to the supposed vital function of the duodenum.

The variety of methods found in a survey of the literature suggested the technical obstacles encountered in duodenectomy. After repeated attempts, extending over a period of several years, we have devised a method which has been attended with some success.

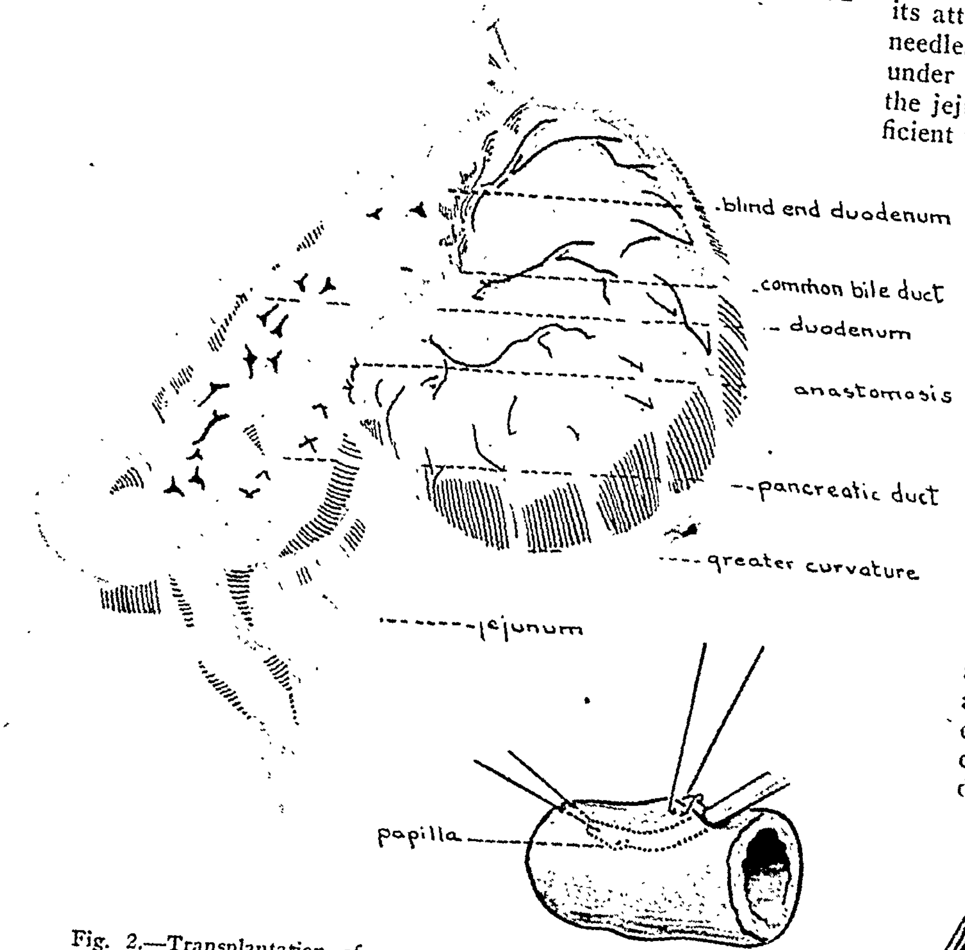

Fig. 2.—Transplantation of common bile duct and major pancreatic duct.

AUTHORS' METHOD

The operation is done in three stages:

1. The abdomen is opened through an incision 10 cm. in length starting midway between the ensiform cartilage and the right costal margin; the rectus muscle is displaced outward; the left index finger locates the hepatopyloric ligament, which is cut, and the finger is passed downward behind the pylorus; the greater omentum is drawn to the left and an opening made through an avascular space in the dorsal mesentery close to the edge of the pancreas; rubber-covered clamps are applied on each side of the pylorus and four ligatures tied (two above and two below); the pylorus is divided on a Kocher director.

The gastric end, which is covered with a warm pad, is laid aside. The mucosa of the duodenal end is dissected from the muscularis for a distance of about 3 cm., and this isolated portion removed. The serosa and the muscularis are infolded so that a portion of the pancreas covers the blind end. The transverse colon is located and drawn outward, carrying with it the first loop of the jejunum. This is brought up in front of the colon and anastomosed to the open pyloric end of the stomach, the proximal part of the bowel at the lesser curvature (Fig. 1). The abdomen is closed. A subcuticular stitch apposes the skin. No dressing is employed. Buttonhole silk is used exclusively in our work.

2. Two weeks later an incision similar to that described above opens the peritoneal cavity. The duodenum is picked up, and the common bile duct identified and excised from the duodenal wall. The mucosa of the excised portion is completely removed. The opening made is closed by Lembert sutures. Wirsung's duct, which is the accessory duct in the dog, is ligated and divided. The gastrojejunostomy is located and a small opening made in the jejunum about 3 cm. distal to the junction. The common bile duct with its attached duodenal wall, held by a thread armed with two needles, is drawn through an opening in the dorsal mesentery under the duodenum. These two needles are introduced into the jejunal opening, and emerge about 2.5 cm. distally. Sufficient traction is applied to draw the duct through the orifice, and the threads are tied on the serosa. One Lembert suture is used to effect closure around the duct.

The duct of Santorini is now found. Its usual location in the dog is at a point about 3 cm. proximal to the place where the pancreas turns away from the duodenum. This duct is transplanted by the same technic as is the common bile duct, about 5 cm. distal to the implantation of the common duct (Fig. 2). The omentum is carefully arranged and the abdomen closed.

3. Following an interval of fourteen days, the abdomen is opened for the third time through the right rectus abdominis. Multiple adhesions are commonly found. The blind duodenal end is sought and liberated sufficiently to allow its being brought to an accessible position. The bowel is opened longitudinally along the surface opposite the pancreas for a distance of about 8 cm. Long hysterectomy clamps are applied parallel to and about 2 cm. from the cut edge. With a sharp uterine curet the mucosa is completely removed. The wall is now divided immediately below the clamps and the remaining edges infolded with a continuous buttonhole stitch. Proceeding distally, this technic is repeated until a point 4 cm. below the duct-bearing portion of the duodenum is reached. Beyond this point a typical resection completes the duodenectomy (Fig. 3).

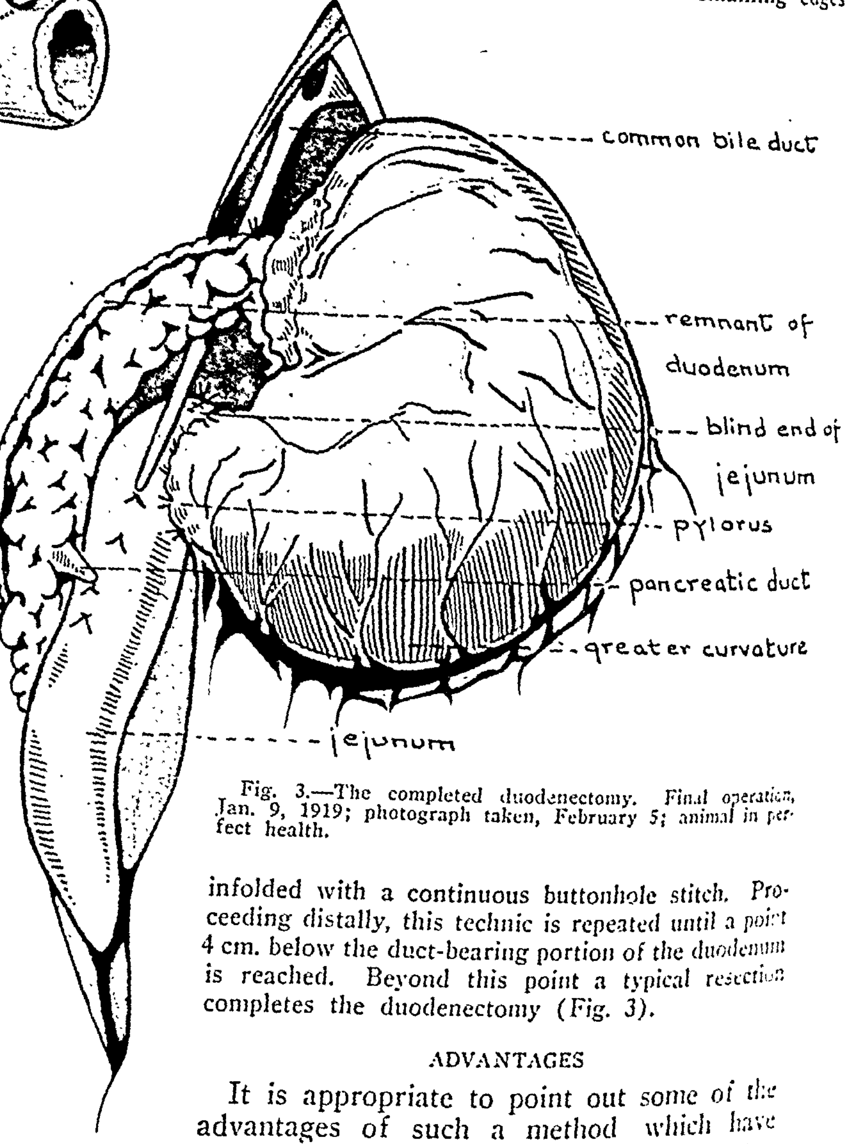

Fig. 3.—The completed duodenectomy. Final operation, Jan. 9, 1919; photograph taken, February 5; animal in perfect health.

ADVANTAGES

It is appropriate to point out some of the advantages of such a method which have been carefully worked out and compared with other procedures.

The gastro-enterostomy described in the first stage is superior to the usual operations because the junction is made at the true physiologic location, the pylorus. This region is undisturbed in the subsequent steps.

By our technic the biliary and pancreatic secretions are preserved. The jejunum is made to serve as a substitute for the duodenum in receiving the digestive juices. In a review of the literature we were unable to find a single instance in which both the common bile duct and the pancreatic duct had been successfully transplanted into the jejunum at one time. Cholecystenterostomy in the dog is frequently fatal. Cholecystogastrostomy disregards well established principles of digestion.

In our opinion the usual technic of intestinal resection cannot be applied to the duct-bearing portion of the duodenum. The final stage, as described, disturbs neither the pancreas nor the functioning alimentary tract, thus reducing to a minimum the after-effects of a severe operation.

CONCLUSIONS

1. The method described permits the complete removal of the duodenum in consecutive operations: (*a*) pylorectomy, closure of the duodenal end, and gastrojejunostomy; (*b*) transplantation of the common bile duct and the major pancreatic duct into the jejunum; (*c*) removal of the duodenum.
2. Dogs thus operated on will live in a normal state of health. The duodenum, therefore, is not essential to life.

ANTHRAX IN A SOLDIER

REPORT OF A FATAL CASE PROBABLY DUE TO INFECTION BY A SHAVING BRUSH *

WILLEY H. NORTON, M.D.
Captain, M. C., U. S. Army; Chief of Laboratory
AND
EDWARD F. KOHMAN, Ph.D.
First Lieutenant, Sanitary Corps, U. S. Army
CAMP JACKSON, COLUMBIA, S. C.

This is the third case of human anthrax at Camp Jackson in the past four months, the first two cases having been reported by Schultz.[1] In this case anthrax bacilli were isolated from a shaving brush made of badger's or of an imitation of badger's hair, and recently purchased by the patient. The case is thought worthy of record because of the interesting pathology, especially the presence of intestinal carbuncles, which are usually associated with infection by the intestinal route, and the complete bacteriologic and chemical findings.

REPORT OF CASE

History.—Private J. B., white, aged 21, was admitted to the base hospital of Camp Jackson, Nov. 21, 1918, complaining of slight headache, dizziness and backache. The previous medical history was negative. The patient was well nourished. He was not acutely ill, having on the neck above the thyroid cartilage an inconspicuous swelling without inflammatory areola, about 1 cm. in diameter, which according to the patient followed several days after the use of a new shaving brush. The latter was purchased for $1, and was said by the manufacturer to be sterile.

On admission the temperature was 100.2, pulse 96 and respiration 20. The leukocyte count was 11,200, of which 83 per cent. were neutrophils, 13 per cent. small mononuclears and 4 per cent. large mononuclears. The leukocyte count on the second day after admission was 24,000, of which 84 per cent. were neutrophils, 3 per cent. small mononuclears, 10 per cent. large mononuclears and 3 per cent. transitionals. On the same day a specimen of urine was positive for acetone, bile acids and bile pigments, and negative for diacetic acid. On the evening of the same day, the red cell count was 3,400,000. The leukocyte count was 31,000, of which 81 per cent. were neutrophils, 17 per cent. small mononuclears and 2 per cent. large mononuclears. The hemoglobin was 100 per cent. The blood at that time was dark and thick.

On the morning of November 23, three days after admission, the patient became nauseated and vomited a grumose material. The vomiting continued and was accompanied by severe epigastric pain. He shortly developed a cyanotic pallor and signs of circulatory collapse. The pulse was not obtained at the wrist, and the heart sounds were barely audible with the stethoscope. The respirations were irregular, somewhat rapid, and occasionally deep and sighing, suggestive of air-hunger. The lungs were clear. The abdomen was distended, tympanitic, and tender on palpation in the epigastrium. The spleen and liver were just palpable. The pupils reacted to light and accommodation. Rigidity of the neck, and the Kernig and Brudzinski signs were absent. Oppenheim's reflex was present on both sides. All the other reflexes were normal. The swelling on the neck had assumed the appearance of a granuloma, and the superficial chain of lymph glands along the anterior border of the right sternocleidomastoid muscle was enlarged. There was slight diffuse swelling over the area outlined by the right sternocleidomastoid muscle. Around the granuloma was noted what was suggestive of a margin of dry vesicles. The center of the lesion showed beginning black necrotic change. There was no pain nor tenderness about the lesion. A smear which was made from a freshly abraded surface showed organisms having the morphologic characteristics of the anthrax bacillus. The blood that exuded from the abraded surface turned black immediately.

The vomitus was positive for blood. Carbon dioxid determination of the blood plasma gave 43.8 per cent. by the method of Van Slyck and Cullen. At 2 p. m. a diagnosis of anthrax was reasonably established, and the patient was given intravenously 160 c.c. of antianthrax serum. No improvement occurred, and to counteract the acidosis determined to be present, 750 c.c. of a 4 per cent. sodium bicarbonate solution were given intravenously. The patient did not react but became progressively worse and died at 8:30 p. m., November 23.

Bacteriologic Examinations.—Shortly before noon, November 23, a smear made from the blood taken from the granuloma showed abundant, large gram-positive capsulated bacilli. In a hanging drop these grew into long filaments in less than an hour, showing the organism to be an aerobe. On blood-agar plates these bacilli developed into characteristic anthrax colonies. A smear from the lesion also showed cocci, which on plates proved to be *Staphylococcus aureus.* Three mice were inoculated, one subcutaneously and two intraperitoneally, with blood from the lesion. All three died within less than twenty-six hours. At necropsy all had numerous anthrax bacilli in the spleen, kidney, and heart's blood. Cultures from these organs all gave characteristic anthrax colonies. At the same time, November 23, two blood cultures taken from the patient—one in the morning and one in the afternoon—were positive for anthrax bacilli. At the time the latter was taken a plate was also made with the blood from the arm, and this gave approximately seventy colonies per cubic centimeter of blood.

Pathologic Examination.—This was made twelve hours after death. Extending from the granuloma on the neck beneath the sternum into the mediastinal tissues there was considerable edema of the tissues, which had a yellowish and gelatinous appearance. This edema to a lesser degree extended upward from the lesion along the right sternocleidomastoid muscle. There were 150 c.c. of dark yellowish fluid in the abdominal cavity. The pleural cavities were free from adhesions or fluid. The heart was normal. Beneath the pleura of both lungs there were numerous petechial hemorrhages, especially marked posteriorly and between the lobes. Both lungs were markedly congested, although no indication of consolidation was present. There was one small hemorrhage found in the liver beneath the capsule, 4 mm. in diameter. The spleen measured 12 by 14 by 2.5 cm. and was soft. The capsule was smooth, bluish, and free from adhesions. The tissue on section was red and pulpy. The congestion was so marked as to obscure the malpighian bodies. The stomach was filled with a dark coffee-ground material. The gastric mucosa was everywhere congested, but no hemorrhagic areas were noted. The omentum and mesentery were greatly thickened by a gelatinous condition of the tissues. The mesenteric lymph glands were enlarged and intensely hemorrhagic. There were five places in the ileum and two places in the descending colon which were red and edematous in appearance and approximately 6 cm. in diameter. Viewed from the mucosa surface these areas presented dilated vessels, at times accompanied by hemorrhage in stellate arrangement, the center of which was gray and nodular, the whole underlying the mucosa, except that in one place the central nodule was ulcerated. Smears from these nodules showed many bacilli. Otherwise, the intestinal walls appeared normal. There was no generalized hyperemia, nor were Peyer's patches conspicuous. The contents of the intestine were of interest. Normal light-brown feces in moderate quantity were found in the entire colon. Above the cecum for some distance, however, the contents were black and pasty. In the upper ileum, brown, normal fecal matter again was found. Above this again in the duodenum and upper jejunum there was found much black, tarry material. Cultures made from the heart's blood gave a pure culture of anthrax bacilli. Cultures from the spleen showed a few anthrax colonies.

Fig. 1.—Intestinal carbuncle (Gram-Weigert stain); × 450.

Microscopic Examination.—The subcutaneous tissues were swollen and the tissue substance filled with a granular, eosin-stained, structureless material in which there was some fibrin. There was marked infiltration with polymorphonuclear leukocytes. The lungs showed the alveolar walls engorged with blood, oftentimes obliterating the alveoli, and in a few places the alveolar walls had ruptured, allowing the alveoli to be filled with red blood cells and a few white cells. The liver, kidneys and suprarenals showed parenchymatous degeneration. The hemorrhagic nodules found in the colon and ileum showed the intestinal wall densely infiltrated with red cells, fibrin and serum. The nuclear elements in these areas no longer took the hematoxylin stain. Numerous large gram-positive bacilli were demonstrated in the subcutaneous tissue, the mesenteric glands and the intestinal nodules by the Gram-Weigert method. A few scattering bacilli were found in the capillaries of the lungs, liver, kidneys and spleen.

Examination of Shaving Brush.—The bristles of the shaving brush recently purchased and used by this patient were washed in about 20 c.c. of physiologic sodium chlorid solution. This washing was centrifuged and the supernatant fluid decanted off and discarded. Fresh physiologic sodium chlorid solution was added to the sediment, and the operation repeated in order to free the sediment from soap. Smears of this sediment showed numerous bacilli but no typical anthrax bacilli. Inoculations of the sediment were made intraperitoneally into a guinea-pig and two mice. In the case of one mouse the inoculating material was first heated at 75 C. for two minutes, in order to reduce the number of organisms other than spores of anthrax. Both animals that received the unheated material died within about twenty-four hours. At necropsy neither showed anthrax bacilli either microscopically or culturally. The mouse receiving the heated material died about three hours later than the other two animals. Microscopic examination of the kidney tissue and of the heart's blood showed large gram-positive bacilli very similar to the anthrax bacillus. Cultures from the kidney showed a large gram-positive bacillus, the colonies of which were not anthrax-like. Inoculations from kidney or liver pulp made subcutaneously into a second mouse did not infect it. A second washing of the brush was made and a washed sediment obtained in a manner similar to that described above. All of this sediment was heated for two minutes at 75 C. Two mice were inoculated subcutaneously at the root of the tail with this sediment. One mouse died within forty-eight hours. Pure cultures of a gram-negative bacillus were obtained on culturing the organs of this mouse. The other mouse died after about seventy-two hours. Smears from the spleen, kidneys, and heart's blood of this mouse showed large gram-positive bacilli, morphologically *B. anthracis*. In a hanging drop this grew into long filaments within an hour. A plate made from the spleen pulp gave anthrax-like colonies, as well as numerous colonies of a comparatively small gram-negative bacillus. The heart's blood on a blood-agar slant

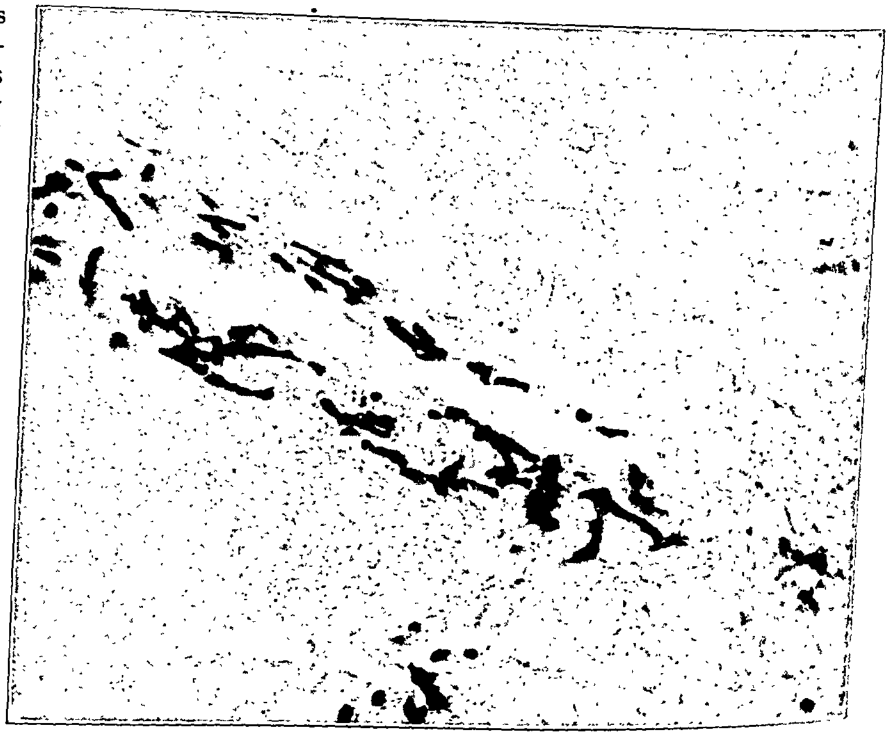

Fig. 2.—Skin carbuncle (Gram-Weigert stain); × 1,000.

gave a few anthrax colonies in pure culture. Material from an anthrax-like colony developed on the place cultivated from the spleen of this mouse was inoculated into another mouse subcutaneously at the root of the tail. This mouse died within twenty-four hours. Numerous bacilli were found in smears of all the organs. These were capsulated and had all the marks characteristic of the anthrax bacillus. Inoculations from the heart's blood, spleen, and kidney on blood-agar gave characteristic anthrax colonies in pure culture. Plates made directly from the heated and washed sediment obtained from the second washing of the shaving brush gave characteristic anthrax colonies mixed with those of numerous other bacteria. The morphology of the organisms of the anthrax-like colonies was typical of that of the anthrax bacillus.

CONCLUSIONS

1. An organism definitely shown to be the anthrax bacillus was found on a new shaving brush, the use of which was followed by a fatal infection. In all probability this brush was the source of the infection. Attention is, however, called to the possibility of the shaving brush being infected by the granuloma on the patient's neck.

2. The clinical course of the disease was such that the diagnosis could not have been made without the laboratory examinations.

3. Intestinal carbuncles may be formed by a blood-stream infection as well as by the alimentary route. Of course, there is a possibility of the anthrax bacilli having gained entrance to the mouth at the time of shaving. However, the intestinal lesions were all, except one, covered by intact mucosa. Attention is called to the fact that these were all recent lesions in the intestine. It appears that there is a definite tendency for anthrax infections to localize in the intestine no matter whether the infection takes place by the blood stream through the skin or the intestinal route.

DESIRABILITY OF CHANGING THE TYPE OF WRITTEN EXAMINATIONS*

GEORGE BLUMER, M.D.
NEW HAVEN, CONN.

The purpose of medical education is not to produce walking encyclopedias of medical knowledge. While the acquisition of the rudiments of medical knowledge is a part of medical education and a somewhat important part, it is nevertheless true that the sum of medical knowledge is so vast that even were it desirable to attempt to teach it, it is not possible for any single human intellect to digest and retain it. Much more important in medical education than the acquisition of mere knowledge is the development of certain specific qualities and habits of thought, the summation of which may be described as the scientific habit of mind.

There is doubtless room for some difference of opinion as to the relative importance of the different mental qualities and attainments that are most desirable in a student of medicine. It is probable, however, that there is tolerably substantial agreement among medical educators as to what these qualities and attainments are. A student of any science must be acquainted with the technical language of that science. He should be able to spell that language correctly and he should possess sufficient mental clarity to enable him to express his views regarding a technical subject in clear and intelligible language. As he must absorb his knowledge from lectures, books and magazines, he should possess a critical faculty, and should be able to separate the wheat from the chaff. He should be able to interpret the various forms of graphic presentation that are used in medical science and practice, such as pulse tracings, physiologic tracings, statistical tables, temperature charts, and the like. He should be able to present his own ideas in graphic form when they relate to subjects capable of being expressed in that way. He should be able to gather facts, and he should be able to reason from facts. He should possess trained powers of observation, he should be able to concentrate on the work in hand, and he should possess the ability to put through any work assigned to him. He should possess health and vitality, and he should know how to keep these necessary attributes.

No one will deny the necessity of submitting the medical student and the recent medical graduate to definite tests in order to permit the university authorities, in the one case, or the state boards of examiners, in the other, to determine their fitness to practice medicine. It does not suffice for the universities or examining boards to lay down a certain course of study that must be pursued in order to graduate and obtain the right to practice. It is essential that the candidate who desires to apply his knowledge to the actual treatment of patients should prove that he or she has mastered to a sufficient degree the principles that underlie the science and art of medicine. Without the safeguard of licensing examinations, the public would be even less well protected than it is at present from fradulent practitioners and the half-baked followers of half-faked cults.

Assuming, then, that there is general agreement that tests of fitness are a necessity in connection with the practice of a profession like medicine, the question arises whether the present methods of testing fitness cannot be improved on. It may be pointed out, in the first place, that the tests applied by the medical schools are usually not the same as the tests applied by the state examining boards. The main distinction lies in the fact that the medical school takes cognizance of the daily work of the student. So far as I know, no state board of examiners pays any attention to this record. In the second place, the number of state boards that give practical examinations is much smaller than it ought to be. In the majority of instances the type of test on which ability to practice medicine is based is the written examination, and it is the written examination that this discussion mainly concerns.

TESTS OF MEMORY

As at present framed, most written examinations are tests of the ability of the individuals taking them to absorb and retain large quantities of knowledge for a brief period. In other words, they are memory tests. As a result of this it is perfectly possible for an individual with a retentive memory who has graduated from an inferior medical school to pass a brilliant examination. Indeed, it is an actual fact that there have been in the past graduates of schools which were practically quiz-compend institutions who were eminently successful in passing state board examinations and obtaining licenses to practice. While the great improvements in medical colleges in recent years renders this situation no longer likely to occur, it is nevertheless still true that most state board examinations put a premium on the individual with a retentive memory and an almost bovine aptitude for regurgitation.

---

* Read before the Annual Congress on Medical Education and Licensure, Chicago, March 4, 1919.

A TEST OF DESIRABLE QUALITIES

The purpose of this communication is to suggest a new type of written examination which will test certain of the qualities that are desirable in medical students and medical practitioners, as well as testing their knowledge. In thinking over the list of desirable qualities mentioned in the early part of the paper, it is clear that not all of them can be tested by a written examination. Some of them must be tested by practical examinations, and can be tested only in that way. This is true particularly of the power of observation and the ability to put through various laboratory tests. There remain, after excluding the qualities that can be tested only in a practical way, certain qualities that can be tested in a written examination. These are:

1. Knowledge of the technical language of medicine.
2. Ability to express ideas graphically.
3. Ability to interpret ideas presented in graphic form.
4. Critical ability.
5. Ability to reason from facts.
6. Ability to present a subject in clear language.

METHOD OF APPLYING TESTS

The method of applying these different tests may be briefly described in order to indicate the practicability of such a written examination:

1. The test of ability to understand the technical language of medicine is obvious. It consists in presenting the student with a list of technical medical terms, beginning with easy terms and ending with the most difficult and requiring the student to define them.

2. The test of the student's ability to express ideas graphically may be illustrated by the following question recently asked in an examination of this sort:

> Draw a diagram illustrating the relationship existing between diseases of the bile passages and diseases of the pancreas. Letter and legend the diagram so as to convey your ideas.

3. The question covering the ability to interpret ideas graphically presented would vary in form according to the subject of the examination. In the case of a clinical subject, a record like a temperature chart could be presented with the request that the student describe and interpret the chart.

4. The test of critical ability consists in presenting to the student a brief quotation from some magazine article, preferably a quotation that contains both truth and fallacy. In this way the student is put in a position in which he must pass judgment on the validity of the statement. It is interesting to note in practice how quickly the individual whose tendency is to hedge can be separated from the students who have real critical ability.

5. The ability to reason from facts is one that is, of course, constantly used both in laboratory and in clinical work, and can best be tested by a method allied to that popularized by Cabot under the name of "case teaching." The student is presented with a history of an actual case, together with the more important clinical and laboratory findings, and is requested to draw his conclusions as to the nature of the case, giving his reasons.

6. Ability to present his ideas in clear language can be judged by a careful reading of the replies to the preceding questions. It is not necessary, of course, to have a special question for this purpose. Ability to spell correctly should perhaps be included as part of the test.

RATING OF QUALITIES

It goes without saying that the different qualities tested in this examination are not all of equal importance and should not all be rated equally. The rating that I have tentatively adopted is as follows:

Knowledge of the technical language, 10 points.
Ability to present ideas graphically, 10 points.
Ability to interpret ideas presented graphically, 10 points.
Ability to write clear English, 10 points.
Critical ability, 30 points.
Ability to reason from facts, 30 points.

The preparation of an examination of this kind, of course, requires more care and involves more expenditure of time than the preparation of the ordinary type of written examination. Any average practitioner can sit down with a textbook and prepare an examination of the ordinary type in a very short time. The extra expenditure of time is, however, compensated for by the much more satisfactory results obtained by the quality tests.

It is very interesting to observe the effect of such an examination on the rating of the students in a given class, as contrasted with the ratings under the old type of examination. The results at once make clear why it is that some men who, during their student career, do not appear to possess more than average ability, during their career as practitioners achieve a degree of success much greater than their teachers expected. A test of this sort shows that some of the most brilliant parrots in a class possess no critical faculty, and that their power of reasoning from facts may be decidedly mediocre. On the other hand, a man who has little capacity for memorizing may in an examination of this sort prove to have excellent critical faculty and a logical mind capable of drawing correct conclusions from the facts presented.

It may be pointed out that this type of examination is applicable to any subject. Each subject has, of course, its own technical languarge in addition to the common language of medicine. Each subject has aspects that can be graphically presented. The literature of each subject must of necessity be subjected to critical analysis, and the facts in connection with each subject must be interpreted after they have been elicited.

CONCLUSION

It is freely acknowledged that the ideas contained in this paper are not original. This is merely an attempt to work out a practical method along lines which have been suggested by the psychologists and have actually been in use in technical schools. Nor is it claimed that the plan suggested is anything more than a beginning. It is quite possible that I have entirely overlooked certain qualities that might be tested in this way, and it is more than likely that the method can be brought to a much higher degree of perfection. My main purpose in this paper is to emphasize the fact that no one kind of test is sufficient to provide a fair basis for the graduation or licensing of physicians, that the daily work of the individual should be taken into account even by state boards of examiners, that practical examinations are absolutely essential, and that the present type of written examination puts a premium on a type of mind that is not particularly desirable in medicine, and is a test of memory rather than a test of desirable qualities. Actual experience with the type of written examination suggested shows that the plan is entirely feasible and that it fulfils the purposes for which it was designed.

PRIMARY AND POSTINFLUENZAL PNEUMONIA

A COMPARISON OF THE LABORATORY FINDINGS

FREDERICK H. LAMB, M.D.
Captain, M. C., U. S. Army; Chief of Laboratory Service,
Base Hospital
CAMP CODY, DEMING, N. M.

This report is based on the laboratory findings, tabulated in summarized form, of two series of pneumonia cases occurring in the base hospital at Camp Cody. One series consists of 178 cases of primary[1] pneumonia admitted between May 1 and Oct. 1, 1918. The other consists of 624 cases of postinfluenzal pneumonia occurring between Oct. 1 and Dec. 1, 1918.

TABLE 1.—MORBIDITY AND MORTALITY INCIDENCE

Primary Pneumonia	Postinfluenzal Pneumonia
Period of time:	
May 1 to Oct. 1, 1918 (5 months).	Oct. 1 to Dec. 1, 1918 (2 months)
Number of cases:	
178 cases, of which 7 were postoperative, 2 posttraumatic.	624 cases developing out of 3,265 influenzas.
Clinical diagnosis:	
Lobar pneumonia, 123 cases; bronchopneumonia, 55 cases.	624 cases, all diagnosed bronchopneumonia, postinfluenzal.
Mortality:	
20 deaths; 11.23%.	240 deaths; 38.4%.
Approximate number of troops in camp:	Oct. 1 to Nov. 1, 1918, 4,500.
May 1 to June 1, 1918, 21,000...	Nov. 1 to Dec. 1, 1918, 10,000.
June 1 to July 1, 1918, 27,000..	
July 1 to Sept. 1, 1918, 32,000...	
Sept. 1 to Oct. 1, 1918, 5,000...	

TABLE 2.—COMPLICATIONS IN WHICH BACTERIOLOGIC INVESTIGATIONS WERE MADE

Primary Pneumonia	Cases	Pr. Ct.	Postinfluenzal Pneumonia	Cases	Pr. Ct.
Empyema:					
Incidence: 12 empyemas out of 178 pneumonias 6.8%			Incidence: 65 empyemas out of 624 pneumonias 10.4%		
Bacteriology of 12 exudates.			Bacteriology of 60 exudates.		
Pneumococcus	2*	16.6*	Pneumococcus	25*	41.1*
Type I	2	...	Type II atypical	12	...
			Type III	2	...
			Type IV	11	...
Streptococcus	10*	83.3*	Streptococcus	23*	38.3*
Hemolytic	7	...	Hemolytic	4	...
Nonhemolytic	3	...	Nonhemolytic	19	...
			Mixed	12*	20.0*
			Strepto. hem. and Pneum. III	3	...
			Strepto nonhem. and Pneum.	7	...
			Strepto. hem. and Pneum. IV	2	...
Meningitis:					
Incidence: 1 case out of 178 pneumonias 0.6%			Incidence: 7 cases out of 624 pneumonias 1.1%		
Bacteriology			Bacteriology.		
Pneumococcus:			Pneumococcus	6*	85.7*
Type I	1	100.00	Type II atypical	3	...
			Type III	1	...
			Type IV	2	...
			Streptococcus:		
			Hemolytic	1	14.3

* Subtotals.

In order to present the comparison more clearly, the summarized findings of the two series of cases will be placed side by side. On the left hand will appear data pertaining to the primary pneumonias, while on the right hand, and directly opposite, will appear data of the same character applying to the postinfluenzal pneumonias. The figures given in the accompanying tables are derived almost entirely from daily laboratory records. No effort is made to coordinate the laboratory and the clinical features. In fact, the primary object of this report is to present a brief, concise comparison of the results of certain common laboratory investigations in two series of cases.

TABLE 3.—BLOOD EXAMINATIONS

Primary Pneumonia	Cases	Pr. Ct.	Postinfluenzal Pneumonia	Cases	Pr. Ct.
Blood cultures:					
Number of cultures 164			Number of cultures 248		
Organisms recovered in 34 cases 20.7%			Organisms recovered in 4 cases 1.6%		
Pneumococcus	30*	89.0*	Pneumococcus	3*	1.2*
Type I	19	...	Type I	1	...
Type II	2	...	Type II	1	...
Type II atypical	1	...	Type II atypical	1	...
Type III	1	...			
Type IV	4	...			
Types I and II	1	...			
Types I and II atypical	1	...			
Types II and III	1	...			
Streptococcus	4*	11.0*	Streptococcus	1*	0.4*
Hemolytic	2	...	Hemolytic	1	...
Nonhemolytic	2	...			
Leukocyte counts:					
Average leukocyte count in 176 cases 21,830			Average leukocyte count in 350 cases 9,480		
8,000 or under	6	3.4	8,000 or under	203	58.0
8,000 to 12,000	12	6.8	8,000 to 12,000	53	15.1
12,000 to 25,000	90	51.1	12,000 to 25,000	82	23.5
Over 25,000	68	38.7	Over 25,000	12	3.4

* Subtotals.

TABLE 4.—SPUTUM EXAMINATIONS

Primary Pneumonia	Cases	Pr. Ct.	Postinfluenzal Pneumonia	Cases	Pr. Ct.
Sputums:					
Number of sputum examinations, 204 (in total of 156 cases).			Number of sputum examinations, 365 (in total of 348 cases).		
Pneumococcus	104*	66.7*	Pneumococcus	216*	62.0*
Type I	43	27.6	Type I	9	2.6
Type II	21	13.5	Type II	7	2.0
Type II atypical	10	6.4	Type II atypical	24	6.9
Type III	8	5.1	Type III	14	4.0
Type IV	22	14.1	Type IV	162	46.5
Streptococcus	27*	17.2*	Streptococcus	91*	26.0*

Type I and Strept. hem.	7	4.5			
Type II and Strept. hem.	4	2.5			
Type III and Strept. hem.	1	0.6			
Type IV and Strept. hem.	13	8.5			

* Subtotals.

It may be stated, by way of explanation, that the laboratory personnel and the technical methods employed during the seven months in which these studies were in progress remained practically the same throughout. Whatever technical errors have been made are proportionately common in both series. For the sake of efficiency in the laboratory, and of conformity in results, the examinations were carried out in a routine manner. Blank outlines indicating the data desirable for each kind of specimen were filled out as the examination of the specimen progressed.

The actual technic of the laboratory investigations has become too well known and standardized, I believe, to require a detailed description here. In general, the sputum "typings" were carried out according to the methods of Cole, Dochez and Avery. Avery's pneumococcus culture medium and his mouse inoculations were both used in the typing of practically all sputums and exudates. By means of blood agar pour plates, streptococci were differentiated into hemolytic and nonhemolytic groups. The blood cultures were made by inoculating 180 c.c. of bouillon with about 15 c.c. of blood, and were examined at twenty-four hour intervals for three or four days.

---

[1] In this report the word "primary" signifies ordinary clinical lobar pneumonia or bronchopneumonia.

COMMENT

It will be seen in Table 1 that approximately three and one-half times as many cases of pneumonia developed during the two months of the influenza epidemic as occurred in the camp during the five preceding months, although the number of troops averaged less than one third during the epidemic. The mortality rate in the postinfluenzal pneumonias was nearly three and one-half times that of the primary pneumonias.

Of the complications shown in Table 2, the incidence of empyema and meningitis was approximately twice as great in the influenzal pneumonia series. The bacteriology of the exudates differed considerably in the two series, as shown in the table.

Positive blood cultures were obtained in 20.7 per cent. of the primary pneumonias, but in only 1.6 per cent. of the influenzal pneumonias; a proportion of 13 : 1. The average leukocyte count in the latter series was considerably less than one half that of the former. Ten and two-tenths per cent. of the primary pneumonias gave a leukocyte count of 12,000 or under, whereas 73.1 per cent. were under 12,000 in the influenzal series.

In Table 4 there is shown a marked difference in the results of sputum "typings." Types I and II pneumococci occurred in 41.1 per cent. of the sputums from cases of primary pneumonia, whereas the same types were found in only 4.6 per cent. of the postinfluenzal cases. Type II atypical and Type III were of about equal ocurrence. Group IV was found in 14.1 per cent. of the primary pneumonias and 46.5 per cent. of the postinfluenzal pneumonias. The hemolytic group of streptococci was encountered more frequently in the primary cases; the nonhemolytic group in the other series.

NOMENCLATURE OF HUMAN ISOHEMAGGLUTINATION GROUPS

M. W. LYON, Jr., M.D.
Captain, M. C., U. S. Army
WASHINGTON, D. C.

In the course of a series of cross agglutinations in order to secure known Group II and Group III serum to keep on hand for grouping individuals for blood transfusions, it became apparent that two systems of designating the four different isohemagglutination groups of men are in use. Few authors[1] refer to the two systems, and the author of the older one is seldom mentioned. While the matter is of little practical importance, it may not be without interest to call attention to the two systems of naming the groups.

The older classification since the existence of four groups has been recognized is that of Jansky.[2] Among others who follow it are Ottenberg,[3] Zinsser,[4] Meleney, Stearns, Fortuine and Ferry,[5] and Edition 1 of the "Laboratory Methods of the United States Army."[6] Here the most common group, the one whose serum is the most agglutinative and whose cells are never agglutinated, is called I. The least common group, the one whose serum never agglutinates and whose corpuscles are always agglutinated except by its own serum, is called IV. Groups II and III embrace those persons whose serum agglutinates each other's cells and the cells of Group IV, but not the cells of Group I, and whose cells are agglutinated by each other's serum and by the serum of Group I and not by that of Group IV. The most commonly encountered of the two reciprocal Groups II and III is designated by Jansky and by every other writer as Group II, and the one less frequently encountered as Group III. Jansky's Groups I, II and III correspond to Groups I, II and III of Hektoen[7] and other early workers when *only three* groups were recognized.

The other system of numbering the groups is that of Moss.[8] Among others who follow it are Sanford,[9] Stitt,[1] Drinker and Brittingham,[10] and Edition 2 of the "Laboratory Methods of the United States Army." Here the common and strong group is designated as IV, the rare and weak group as I. Groups II and III have the same significance with Moss as with Jansky.

The arguments for following the Jansky classification are its priority, and its rational method of numbering the groups inversely according to their frequency of occurrence. The argument for following the Moss classification is its apparently wider adoption.

Explanatory or partially explanatory words might be used with propriety for designating the groups, such as sthenic and antisthenic for Jansky's Groups I and IV, and parasthenic and antiparasthenic for Groups II and III.

Vaccine Treatment of Otitis Media.—In the *Japan Medical World,* Jan. 26, 1919, p. 267, T. Tanaka reports good results from autogenous vaccines made from secretions from the ear or even from the nose if the ear is not discharging. The treatment is effectual in the acute phase or as the otitis is just passing into the chronic stage. The vaccine therapy is peculiarly effectual in otitis media in infants, and the author emphasizes the importance of curing the disease in this early stage as there is no doubt that otitis media in adults is often the result of infectious processes in childhood. The severe pain of otitis media in infants, it is stated, abates and the pathologic process is arrested under the vaccine treatment. The author says that the importance of this is evident as we realize that the staphylococcus, the germ usually involved after the process has persisted for any length of time, is particularly destructive of bone tissue. Ordinary symptomatic treatment does not reach the remoter regions of the lesions, and the destructive process may continue in the depths without any clinical manifestations, while the effect of the vaccine is felt at all depths. The cure is complete under five or six injections, namely, in ten or twelve days; the discharge usually ceases in four or six days. He uses 0.3 mg. of bacteria per cubic centimeter of the physiologic saline, heating this suspension to 30 C. for thirty minutes. After heating, phenol is added to make a 0.5 per cent. solution. In acute cases the intervals are forty-eight hours; in the chronic cases, two or three days. The initial injection dose is 0.1 or 0.15 c.c. for infants and 0.25 for adults, increasing the doses until 1 c.c. is reached, and then recommencing with the inital dose. Tanaka reports an apparently complete cure in 95 per cent. of the acute cases in infants and in 75 per cent. of the chronic cases.

HOSPITAL SERVICE IN RURAL COMMUNITIES

A PRELIMINARY REPORT

Prepared by Ernst C. Meyer, Director of the Department of Surveys and Exhibits of the Rockefeller Foundation, International Health Board
New York

INTRODUCTORY

Public health and sanitation received their first impetus in the urban centers, and quite naturally so, for here the need was greatest. Such extraordinary progress has since been made that the city can claim precedence over the once much vaunted health of the open country. Both old and young in our urban centers live longer and suffer less from sickness than do the inhabitants of the rural regions.

The great national conservation and country life investigations were strong recent influences which brought to the foreground the problem of rural sanitation. Medical inspection of schoolchildren in both urban and rural regions has added many definite data.

Hospitals and health, in almost as intimate a manner as physicians and health, have always been closely associated in the public mind. It was quite natural, therefore, that the rural hospital problem should come to the fore with the rural health problem. Country people have in the past been peculiarly removed from proper hospital care, with consequent unnecessary loss of life and health. Consciousness of this fact has gradually permeated from the medical profession and public health officers to the general population. With it has come the modern movement for rural hospitals based in growing degree on public demand rather than on professional insistence.

But while this educational enlightenment was taking place, the relation of country and city changed markedly. Automobiles, telephones, good roads, motor ambulance service, and other improvements in communication and transportation have done much to span the chasm between the farm-house and the city hospital.

The administration of the first scattered rural hospitals quickly demonstrated the fact that these hospitals must of necessity be of an entirely different type from the city institution. While this would seem self-evident, it is, nevertheless, interesting to record that desperate efforts have been made in the past, and even now are being made, to pattern the rural hospital after its city prototype and to make it express in its routine the large aims of the city institution: treatment of the sick; provision of educational facilities for medical students; investigation of disease; and, more latterly, social service in health for the population with which the city hospital comes in contact.

Gradually it has come to be recognized that the rural hospital can never aspire to the form of service rendered by the city hospital. Adequate treatment of the sick is circumscribed by difficulty in getting proper buildings, efficient staffs of physicians, and well-trained nurses. Educational work is seriously limited by scarcity of clinical material. Research is largely out of the question for the same reason, and because of lack of proper equipment and of ability on the part of staff members to do that kind of work successfully. Lack of vision in some cases, and lack of assistance in others, has prevented social work by rural hospitals, which has distinct possibilities, from assuming the importance that it deserves.

Constantly improving means of communication and transportation are drawing a steadily increasing proportion of country cases to city hospitals. This, coupled with the obvious fact that the ideals of the city hospital are not attainable in the country, has forced supporters of the rural hospital movement to seize on some new idea to justify the community hospital. The original functions of a hospital, as outlined above, have been put more and more into the background, whereas the idea that the rural hospital should be above all else an *educational institution*, through which the community may be taught the fundamentals of hygiene and right living, has been steadily given more prominence. Coupled with this has come the suggestion that the rural hospital may be made a useful mechanism in surveying community conditions and needs in matters of health and sanitation.[1]

A shifting of the aim and purpose of the rural hospital from distinctly hospital service to the educational field raises a number of serious questions which should be answered before too great an impetus is given to this new aspect of the movement. Is it necessary to proceed with the construction of a relatively expensive building and to provide for its maintenance from year to year in order that its halls may be made the nucleus for an educational movement? Is this the most economical and efficient, or even indispensable method for educating a community in matters of health and sanitation?

To what extent is the rural nurse an effective entering wedge for public health work? Should the whole-time health officer properly follow the nurse when public appreciation of greater expenditures has been secured through the work of a nurse? May the rural hospital problem shape itself very differently in terms of need for hospital service after a nurse and health officer have been active in a community for some years, and after public and private health services and needs have been determined and correlated?

Attention must also be given to the relation of the rural hospital to a general community health program. And what is the relation of such a health program to other programs of local government and welfare service? The hospital represents merely one factor in public health work and private medicine. Public health work again is but one factor in the general program of public administration. One must needs keep in mind that funds must be provided by a community for the financing of all its various public services; for the general government purposes of the legislative, executive and judicial departments; and for the special services of protection of persons and property, of education, of recreation, of charities and corrections, of highways, and last, though by no means least, of health, sanitation, and hospitals.

Hospitals and other institutions are being maintained or, where lacking, their maintenance is being urged, for the care of the insane and the feebleminded, for

Vaccine Treatment of Otitis Media.—In the *Japan Medical World*, Jan. 26, 1919, p. 267, T. Tanaka reports good results from autogenous vaccines made from secretions from the ear or even from the nose if the ear is not discharging. The treatment is effectual in the acute phase or as the otitis is just passing into the chronic stage. The vaccine therapy is peculiarly effectual in otitis media in infants, and the author emphasizes the importance of curing the disease in this early stage as there is no doubt that otitis media in adults is often the result of infectious processes in childhood. The severe pain of otitis media in infants, it is stated, abates and the pathologic process is arrested under the vaccine treatment. The author says that the importance of this is evident as we realize that the staphylococcus, the germ usually involved after the process has persisted for any length of time, is particularly destructive of bone tissue. Ordinary symptomatic treatment does not reach the remoter regions of the lesions, and the destructive process may continue in the depths without any clinical manifestations, while the effect of the vaccine is felt at all depths. The cure is complete under five or six injections, namely, in ten or twelve days; the discharge usually ceases in four or six days. He uses 0.3 mg. of bacteria per cubic centimeter of the physiologic saline, heating this suspension to 30 C. for thirty minutes. After heating, phenol is added to make a 0.5 per cent. solution. In acute cases the intervals are forty-eight hours; in the chronic cases, two or three days. The initial injection dose is 0.1 or 0.15 c.c. for infants and 0.25 for adults, increasing the doses until 1 c.c. is reached, and then recommencing with the inital dose. Tanaka reports an apparently complete cure in 95 per cent. of the acute cases in infants and in 75 per cent. of the chronic cases.

STATE BOARD STATISTICS FOR 1918

PRESENTATION BY THE COUNCIL ON MEDICAL EDUCATION OF RESULTS OF STATE BOARD EXAMINATIONS

On pages 1138 to 1147 are three tables, A, B and C, giving in detail the results of the various state medical license examinations held during 1918. Full reports were obtained from all state licensing boards and were carefully verified.

Tables A and B, when read from left to right, show for each medical college named (*a*) the number of graduates appearing for examination in each state, (*b*) whether they passed or failed, (*c*) the total number examined during the year, (*d*) the number who passed, (*e*) the number who failed, (*f*) the percentage of failures, and (*g*) the number of states in which graduates of that school appeared for examination. Read from above downward, they give the results by states, showing (*h*) the number registered and rejected from each college, (*i*) the total numbers examined, registered and rejected, and (*j*) the percentage of rejections. The majority of graduates take the license examination in the state in which the college is located, as shown by the dark diagonal zone of figures passing from the upper left to the lower right corner of each table. These tables are worthy of careful study, since important deductions are possible. The marginal numbers will enable one to follow readily the line for any college.

Caution in Forming Conclusions

In making comparisons on the basis of these statistics, several factors should be kept in mind. The number examined is important, since, if all other conditions are equal, the larger the number of graduates examined, the more accurate is the finding. But other conditions are seldom equal. The number of states in which a school's graduates have been examined is important. The larger this number, the more accurate will be the conclusions. Again, the character of the board making the examination and the methods employed are important factors to be considered, since some boards refuse to examine graduates of inferior medical colleges, while others (see Table I) not only examine graduates of all medical colleges but also admit osteopaths to the physician's and surgeon's examination. Some boards also hold careful examinations which include practical laboratory and clinical tests, or they mark the papers more severely, while others, especially partisan boards, are very lenient. Although conditions are undergoing a steady improvement, it is still true that the character of the license examinations as usually conducted is much more lenient than the examinations required in other countries. It is particularly important, in forming conclusions based on these statistics, to note for each college the states in which its graduates are not admitted to examination—information set forth with these statistics in Table D.

Graduates of All Years Examined in 1918

Table A shows the results for all candidates who took examinations in 1918, regardless of the years in which they graduated. This shows that altogether 3,637 candidates were *examined* last year, as compared with 4,730 in 1917, 4,850 in 1916, 5,313 in 1915 and 5,570 in 1914. There has been a steady decrease each year since 1906, when 8,035 physicians were examined. The decrease each year has been due largely to (*a*) the larger registration through reciprocity, and (*b*) the general diminution in the number of medical colleges, students and graduates. The marked diminution this year is due to the enlistment of so many physicians for military medical service. Of those examined this year, 13.3 per cent. failed, as compared with 14.1 per cent. in 1917, 15 per cent. in 1916, 15.6 per cent. in 1915 and 21.6 per cent. in 1914. This reduction in the percentages of failures indicates improved medical teaching, since there are reasons to believe that methods of examination have not been relaxed.

There were 80 medical colleges in the United States granting degrees in 1918 which had graduates examined, as compared with 89 in the years 1917 and 1916, 93 in 1915 and 96 in 1914. There has been a decrease of 73 since 1905, when graduates from 153 medical colleges were examined. The statistics covering schools which have ceased to exist are included in the line for "miscellaneous colleges."

Graduates of Canadian schools were examined in twelve states, more appearing, naturally, in the border states. The figures for the Canadian colleges are given separately in order to show the number of candidates coming from each, and to show the successes of their graduates at the examinations. Altogether, 29 candidates from Canadian colleges were examined, of whom 11, or 37.9 per cent., failed. Foreign graduates were examined in 14 states, the total number being 45, and of his number 17, or 37.8 per cent., failed. In 1917 there were 79 foreign graduates examined. The largest number of foreigners examined in any state in 1918 was 10 in New York, where 8, or 60 per cent., failed.

Undergraduates and Osteopaths Examined During 1918

For the last three years the few undergraduates examined have been accidental instances due evidently to imperfect credentials. In 1906, there were 703 undergraduates examined, and 342 were licensed. Colorado is now the only state which will knowingly admit nongraduates to its examinations, but only four have been licensed in that state in twelve years. The door has been closed, therefore, against the admission to practice of those whose medical training is known to be incomplete. At present, however, some boards are registering as physicians and surgeons, by examination or by reciprocity, graduates of osteopathic colleges—no one of which compares favorably with even the lowest grade Class C medical college—even though two of these states—Colorado and Texas—refuse to recognize Class C medical schools! (See Table D on page 1148).

During 1918, in California, 133 graduates of osteopathic colleges were admitted to the regular examination for licenses as physicians and surgeons, and of this number 77, or 58.3 per cent., were granted licenses. Of the total examined, 58 were given merely an oral examination, and of this number, 34, or 58.6 per cent., were registered. In Colorado, of 26 osteopaths examined, 21, or 80.8 per cent., were granted licenses as physicians and surgeons (see Tables H and I).

Recent Graduates Examined During 1918

Table B gives the results for graduates of 1914 to 1918, inclusive, examined during 1918. This table is important, since it deals with recent graduates, and is, therefore, the fairest basis for comparison between colleges. Of all candidates examined in 1918, 2,984, or 82.1 per cent., were recent graduates, and of this number, 9.3 per cent. failed, as compared with 13.3 per cent. for all candidates.

Old Practitioners Examined During 1918

Table C is so arranged as to show in comparison the results for graduates of all years (first column), for recent graduates (second column), for graduates of 1913 and previous years (third column), and for graduates of 1918 (fourth column). Of the graduates of 1913 and previous years—"old practitioners"—479 were examined, and of this number 146, or 30.5 per cent., failed, as compared with 9.3 per cent. of failures for recent graduates. This high percentage of failures is due largely to the long time these candidates have been out of college and to the fact that they are commonly required to take the same examination as recent graduates. Justice to these older physicians, who have been licensed, but who, for good reasons, desire to change their locations, is a strong argument for interstate reciprocity in medical licensure; for the use of practical examination by which they

TABLE D.—NONRECOGNITION OF MEDICAL COLLEGES

This Table, Based on Official Reports, Shows the Numerous Pitfalls to Be Avoided by Prospective Medical Students

Colleges marked (x) have been reported as not recognized by the states in the columns of which the letter appears

Marginal Number	COLLEGE	Classification by Council on Medical Education †	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47	48	49	50	Reported Non-Recognition by State Licensing Boards			Marginal Number

---

* *Nine medical colleges give only the first two years of the medical course.*

1. Rated in Class C when last inspected—1912. Has united with the Chicago Hospital College of *Medicine.* Both are reported as not recognized by the Illinois Department of Registration and Education.

2. Formerly the Central College of *Osteopathy;* in 1917 became the Central College Medical Department; present title in 1918.

† Classification revised to March 15, 1919.

3. This college is an offshoot of the *Eclectic* Medical University, an institution rated in Class C. *It is* reported as not recognized by the Missouri State Board of Health.

(x) According to official reports the licensing boards of the states thus indicated do not grant full recognition to, or have taken action refusing to *admit* to their examinations graduates of, the colleges marked by this letter—x.

STATE BOARD STATISTICS FOR 1918

CONCLUDED FROM PAGE 1137

may show their skill in diagnosis and treatment, or for special percentage allowances for years of active practice. The total number of these candidates is diminishing each year as state licensing boards extend the provision for reciprocity, or for the endorsement, without further examination, of licenses granted by other states where a physician's qualifications are otherwise satisfactory. As a rule, the states which do not have reciprocal relations with other states (Florida, Massachusetts, Montana, Oregon and Washington, see Table H) examined the largest numbers of old practitioners.

Total Ex. in 1918	3140	10.2	2881	8.8	259	25.4	2098	5.3		

This table gives data relating to the medical colleges in each state. For example, it shows that, of all the medical schools in Massachusetts, 260 graduates of various years were examined by state boards during 1918, and of this number, 11.5 per cent. failed. Of the 232 who graduated in recent years (1914 to 1918 inclusive), 11.7 per cent. failed; of the 28 who graduated previous to 1918, 9.0 per cent. failed, and of the 186 graduates of 1918, 6.5 per cent. failed.

The ninth column gives the rank of each state group of colleges according to the number of graduates examined. The Illinois group of colleges leads, having 559 graduates examined by state boards during 1918, followed by New York with 518, Massachusetts with 260, Pennsylvania with 256 and Tennessee with 212.

The last column gives the rank of each state group of colleges according to the success of the graduates at the examinations. It is interesting to compare the figures of these two last columns. While the Illinois group ranks first according to the number examined it ranks eleventh in the success of its graduates at the examinations. While Tennessee ranks fifth as to the number examined, it ranks as the twentieth (the lowest place) in the success of its graduates at the examinations.

Graduates of 1918 Examined During 1918

Table C also gives the results for the graduates of 1918 who were examined during the year by the state boards, and shows that 2,149, or 59.1 per cent., of all candidates examined during the year graduated in 1918, including three who graduated from Canadian medical colleges. Educational statistics show that the medical colleges of the United States graduated 2,807 students last year (including 137 for whom diplomas were withheld until a year's internship in a hospital has been completed); therefore, 76.6 per cent. of all graduates in 1918 took examinations for license during that year. In some of the states, graduates in medicine are allowed to serve as hospital interns without first becoming licensed practitioners, which doubtless accounts for some of the remaining 23.4 per cent. Others probably enlisted as medical officers of the United States Army or Navy without first obtaining licenses. Of the 1918 graduates examined, 116, or 5.4 per cent., failed, as compared with 5.7 per cent. in 1917; 7.4 per cent. in 1916; 7.5 per cent. in 1915, and 12.7 per cent. in 1914. A steady improvement in recent years in the qualifications of medical graduates is apparent from these figures.

Nonrecognition of Medical Colleges

Table D shows for each college, from official reports, the states in which its diplomas are not given unqualified recognition. Nonrecognition is expressed by different terms in different states. Some boards list colleges as "not in good standing"; some give them as "not reputable"; in New York full recognition is given only to colleges which are "registered," and in Michigan colleges are divided into groups, only those of Group 1 having full recognition. This table also shows the latest rating given to each college by the Council on Medical Education.

TABLE 1.—RECOGNITION OF MEDICAL COLLEGES (BASED ON TABLE D)

	Number of Colleges
Recognized by all state boards	57
Not recognized by 1 to 3 state boards	12
Not recognized by 7 to 18 state boards	12
Not recognized by 33 to 39 state boards	12
Total	93

From the point of view of the prospective student who may be selecting a medical college, the facts in Table D are of extreme importance. There are 57 medical colleges now having complete recognition in all states. There are 12 others for which the few instances of nonrecognition are due to certain technicalities in state board requirements. If the student gets his medical training in one of the remaining 24 colleges, he will find on graduation that his diploma is not recognized in from 8 to 39 states!

Without the information published in Table D, these state board statistics would be not merely incomplete—*they would be actually misleading.* For example, 25 graduates of the Kansas City (Mo.) College of Medicine and Surgery were examined in 1918. Of these, 23 (92 per cent.) were examined by the Arkansas Board of *Eclectic* Medical Examiners, all of whom passed, while 2 were examined by the Eclectic Board of Connecticut, of whom 1 candidate failed. The statistics show only 4 per cent. of failures, which would make this college appear to belong among the better grade medical schools of the country. Quite different the picture, however, when the facts are known, as set forth in Table D, that this college is reported as not recognized *in its home state* and in 33 other states, and that for its very existence it depends on the acceptance of its graduates by the Eclectic boards of Arkansas and Connecticut! The figures obtained for the last several years indicate that neither the Kansas City College

TABLE 2.—SOURCE OF CANDIDATES REGISTERED BY EXAMINATION

Graduates of	1917		1918	
	Number	Per Cent.	Number	Per Cent.
Class A medical colleges	2,827	69.6	2,109	66.9
Class B medical colleges	813	20.0	541	17.2
Class C medical colleges	255[1]	6.3	288[2]	9.1
Miscellaneous medical colleges	124	3.1	185	5.9
Foreign medical colleges	42	1.0	28	0.9
Totals	4,061	100.0	3,154	100.0

1. Of this number 73 were graduates of osteopathic colleges licensed in California as "physicians and surgeons."
2. Of this number 98 were osteopaths, including 77 registered in California and 21 in Colorado.

of Medicine and Surgery nor the Arkansas Eclectic Board could exist without the other.

During the six years this table has been published, the percentages of fully recognized colleges were, respectively, 29.0, 32.3, 43.7, 65.6, 57.3 and 61.3. This shows a decided improvement in the medical colleges. Thirty-nine state licensing boards, to some extent at least, are utilizing their legal power to refuse recognition to medical colleges which do not meet the requirements in the respective states. In the other eleven states, however, and in the District of Columbia, this table indicates either that the practice acts do not give the boards authority to enforce a requirement of reasonable standards, or else that the boards are not exercising that authority. It is evident that if the graduates of low-standard medical colleges are not eligible for license in the majority of states, they will flock to the other ten which still grant them recognition. These ten states—Arizona, California, Idaho, Kansas, Massachusetts, Nevada, Oregon, Utah, Washington and Wyoming—and the District of Columbia, therefore, will remain the dumping ground for the output of low-grade medical colleges, until the licensing boards obtain the needed legal authority, and until they take action in the matter. Arkansas and Connecticut are also registering through their separate sectarian licensing boards graduates of medical colleges not recognized in the majority of other states. No examinations were held during the year by the Arkansas Homeopathic Board, and from the Florida Eclectic Board no report was received.

Source of Candidates Registered by Examination

Of the 3,154 physicians registered by examination in 1918, 2,109, or 66.9 per cent., graduated from Class A medical colleges; 544, or 17.2 per cent., were from Class B medical colleges; and 288,[1] or 9.1 per cent., were from Class C medical colleges. Of all candidates examined, 213, or 6.8 per cent., came from medical colleges which have ceased to exist and from foreign medical colleges. A comparison of these figures with the results for 1917, as shown in Table 2, will be interesting.

---

[1] Of this number, 98 were graduates of osteopathic colleges who were licensed as "physicians and surgeons" in California and Colorado.

This table is interesting, since it gives data relating to the 26 larger medical colleges arranged according to the number of graduates examined. This allows of comparison between colleges having classes of nearly equal size. Loyola University School of Medicine had the largest number of graduates examined in 1918. The position was held by the Chicago College of Medicine and Surgery in 1913 to 1917, inclusive; by the University of Illinois College of Medicine in 1906, 1907 and 1912; in 1908 by Jefferson Medical College, and in 1909, 1910 and 1911 by the University of Louisville Medical Department. The first place from the standpoint of the number examined, however, does not always mean [illegible] of scholarship. Note the percentage of [illegible] ercentages are for the New York Homeo- [illegible] Meharry Medical College, 32.4; St. Louis [illegible] geons, 28.0; and the Chicago College of Medicine and Surgery, 23.2.

Of the 5 colleges having 100 or more examined, only 2 have failure percentages of less than 10, while the others stand out prominently with large failure percentages.

Of the 21 colleges having between 40 and 100 graduates examined, 13 had failure percentages of less than 10, 4 had failure percentages between 10 and 20 and 4 had failure percentages of over 20 per cent.

The average percentage of failures for these larger colleges for graduates of 1913 and previous years was 23.6; for graduates of 1914 to 1918 inclusive (recent graduates), 10.1; for graduates of 1918, 6.5, and for graduates of all years, 11.1. Of the 3,140 graduates of the 80 colleges in the United States which had graduates examined by state boards in 1918, these larger (32.5 per cent. of all) schools furnished 1,992, or 63.4 per cent., of the graduates examined.

Study of Totals and Percentages

A study of totals and percentages as compared with previous years is of interest. The total *examined* in 1918—3,637—is the lowest number of candidates examined for license in any year since the compiling of these statistics began (see Table 3). The number examined was 1,093 less than in 1917; 1,213 less than in 1916; 1,676 less than in 1915, and 4,398 less than in 1906, when 8,035 candidates were examined. Statistics regarding physicians licensed in the various states by reciprocity and by other methods are given in Tables H, I, J and K. By all methods—examination, reciprocity, under exemption, etc.—4,185 physicians were licensed during 1918, or 1,238 less than in 1917, 1,687 less than in 1916, and 3,680 less than in 1906, when 7,865 physicians were licensed.

Other deductions from the larger tables, presented in Tables E, F and G, are worthy of special study.

This table gives the number of candidates registered and rejected on examination by each state during each of the last five years. The last four columns give the totals for the five years and the percentage rejected by each state.

Three states registered over 1,000 candidates by examination in the five years, these being New York, Illinois and Massachusetts. Over 2,000 were registered in only two states, New York with 2,698 and Illinois with 2,294. Altogether 20,194 physicians were registered by examination in five years, an average of 4,039 each year.

The five highest percentages of rejections for the five years were in South Carolina, 37.7; Alabama, 35.2; Oregon, 29.8; Montana, 29.3; Tennessee, 28.5. Until 1916 Massachusetts, Oregon and Tennessee included nongraduates among those examined during the last five years, and for that reason would be expected to have higher percentages rejected. On the other hand, in several states the boards refused to recognize certain colleges and eliminated many candidates prior to the examination by a scrutiny of credentials, and as a result the percentages of failures on examinations are lower than otherwise would be the case. For rejected only 4.3 per cent. of those who took their examinations. aduates of sixteen medical colleges are not eligible for examinations. This table therefore should be studied Table D.

percentages were in Vermont, 0.8; Washington, 1.0; an, 3.1, and Minnesota, 3.3.

Totals	2710	333	111	972	59	4185

* Nongraduates.

This table shows the total number registered during 1918 in each state by the various methods. The first three columns show those registered by examination: the first column showing the recent graduates registered, the second column the old practitioners (graduates of 1913 and previous years) and the third column shows a few nongraduates and osteopaths who were given licenses as physicians and surgeons. The fourth column shows the number licensed through reciprocity, by endorsement of other state licenses and by certificates of the National Board of Medical Examiners. The fifth column shows those licensed under various exemption clauses in the practice acts, such as because of national fame or by recognition of diplomas (New Mexico). California granted the physician's license to 77 out of 133 applicants who graduated from osteopathic colleges. Of these, 34 were given merely an oral examination.

It is interesting to note that as a rule states which registered large numbers through reciprocity, such as New Jersey, Oklahoma and Michigan, for example, examined very few old practitioners. The large registration through reciprocity in California is due to the liberal provision in the recent medical practice act providing for the recognition of licenses granted in other states. There were no reciprocal registrations reported for ten states, including Alaska.

The last column shows the total number of physicians registered by all methods in each state during the year. Only three states registered over 300 each, these being New York, 496; Illinois, 392, and California, 342. Seventeen states registered less than 50 each. The largest registration was 496 in New York, and the smallest was 1 in Alaska. The total registered by all methods was 4,185, a decrease of 1,238 below the total registered in 1917. This marked decrease is undoubtedly due to the war enlistments.

STUDY OF COLLEGES BY STATE GROUPS

Table E gives the results for the group of colleges located in each state. It shows what states are furnishing the largest number of physicians, and the failure percentages indicate the kind of training these colleges are furnishing, so far as may be judged from the results of state board examinations. Of the thirty-one states having medical colleges which grant degrees, nine furnished 100 or more candidates examined, four states furnished more than 200 each, and two furnished over 500 each. Illinois furnished 559 graduates, the largest number, followed by New York with 518, Massachusetts with 260, Pennsylvania with 256, and Tennessee with 212. Of the thirty-one groups of colleges, twenty-one had failure percentages of less than 10 per cent., eight had failure percentages between 10 and 20, and two—South Carolina and Tennessee—had 20 per cent. or more of failures. Other deductions are given in the legend to the table.

STUDY OF LARGER COLLEGES

Table F is also based on the three large tables, and gives the results of state board examinations as they affect the twenty-six largest medical colleges. Although these colleges represent 32.5 per cent. of the eighty medical colleges in the United States having graduates examined, they furnish 63.4 per cent. of all candidates for license coming from medical schools of the United States. This table shows, however, that the graduating of large classes by a medical college does not prove excellence of teaching, since three of the colleges having 100 or more examined have high failure percentages. The larger the college from the standpoint of students and graduates, the more serious is inferior teaching ability, as indicated by a high failure percentage. In fairness both to medical students and to the public, such schools should strengthen their teaching facilities or reduce the size of their classes.

TOTAL RESULTS FOR FIVE YEARS

Table G shows the number registered and the number rejected in each state for each of the past five years. A comparison of this table with the statistics in the last educational number of THE JOURNAL (Aug. 17, 1918, p. 544, Table 11) shows—what would be expected—that the states having the largest number of medical graduates examined the largest

1. Of the 81 physicians licensed in Arkansas, the Regular Board licensed by examination 7 Class A, 28 Class B and 7 miscellaneous graduates and by reciprocity 5 Class A, 4 Class B and 4 miscellaneous graduates, a total of 13. The Eclectic Board licensed by examination 26 Class C graduates. The Homeopathic Board reported no candidates licensed either by examination or by reciprocity.

2. Of the 105 graduates of Class C colleges licensed in California, 77 were graduates of osteopathic colleges which are not generally recognized as medical colleges by state licensing boards, and 34 of these were required to take only an oral examination. Altogether 133 osteopaths were admitted to the examination for licensure as physicians and surgeons and 77 were so licensed.

3. Of the 24 graduates of Class C colleges licensed in Colorado, 21 were graduates of osteopathic colleges, institutions inferior in most respects to Class C medical schools which are reported as not recognized in Colorado.

4. Texas licensed 3 Class C graduates by examination (although Class C colleges are reported as not recognized) and 18 Class C graduates (including 11 osteopaths) were licensed by reciprocity, a total of 21.

This table shows the classification of the colleges from which most of the physicians graduated who were licensed in 1918. Graduates of colleges which became extinct prior to 1907 who were examined, and all reciprocity licentiates who graduated prior to 1907, are unclassified and included under "miscellaneous" since it was in 1907 that the Council on Medical Education completed its first classification of all medical colleges.

It will be seen that five states accepted Class C graduates through reciprocity where they did not license any by examination. On the whole, however, 287 were licensed by examination where only 54 were registered through reciprocity.

By both examination and reciprocity, the largest numbers of Class C graduates were licensed in California, 116 (including 77 osteopaths); Missouri, 52; Arkansas, 26 (all by the Eclectic Board); Colorado, 24 (including 21 osteopaths); and Texas, 21. The largest numbers of Class B graduates were licensed in Illinois, 161; California, 69; Tennessee, 58; New York, 44; Ohio, 33, and Arkansas, 32.

Of all physicians licensed, 2,456, or 58.7 per cent., were graduates of Class A medical schools; 682, or 16.3 per cent., from Class B schools; 342, or 8.2 per cent., from Class C schools, and 705, or 19.2 per cent., from miscellaneous colleges.

TABLE J.—PHYSICIANS REGISTERED THROUGH RECIPROCITY BY STATE EXAMINING BOARDS DURING 1918

* U. S. Army, Navy and Public Health Service.

This table shows the number of physicians registered by each state through reciprocity during 1918. Read from left to right, it shows the total number of physicians registered through reciprocity in the state named and the number of such candidates coming from each of the states named at the top of the various columns. Read from above downward, the figures show the number of physicians who left the state named at the head of the column and went to each of the states named in the corresponding lines, and at the bottom the total number of candidates leaving the state to go elsewhere. For example, read from left to right, the table shows that Maine registered five candidates through reciprocity in 1918 and that, of these candidates one came from Illinois, one from Ohio and three from Vermont. Read from above downward the table shows that from Maine two candidates each went to the District of Columbia and New Jersey, one each to Delaware, Indiana, Nevada and Virginia, the total leaving the state to go elsewhere being eight. The line at the bottom shows in what states physicians who registered through reciprocity obtained their original licenses. From Illinois 125 candidates, the largest number, obtained their original licenses. New York follows with 74, Missouri with 65, Pennsylvania with 57 and Iowa with 40. The total number licensed by indorsement of licenses or certificates obtained in other states was 972.

Totals	1355	1314	1271	1279	972	6191

This table shows that 6,191 candidates were registered through reciprocity during the last five years.—Registration by reciprocity gradually increased from 1905 to 1914, since which time there has been a gradual decrease as the total of physicians licensed by other methods has decreased. This year the marked decrease in the total registered has been due largely to the war. A study of the totals for the different states shows that of the 6,191 registered during the five years 874, or 11.1 per cent., obtained their original licenses in Illinois. New York could easily lead Illinois but reciprocal relations have been established with only seven other states.

Seven states—Connecticut (regular board), Florida, Massachusetts, Montana, Oregon, Rhode Island, and Washington—do not have reciprocal relations and would not appear in this table except for the fact that some states, like California, Colorado, Delaware, New Hampshire, New Jersey and North Carolina will accept a physician's credentials if satisfactory, whether the state issuing the original license returns the favor or not.

number of physicians. New York leads, having examined 3,597 candidates in five years, followed by Illinois with 2,958. The five states having the next highest numbers are Massachusetts with 1,382, Pennsylvania with 1,278, Tennessee with 1,184, and Missouri with 1,027.

TOTAL REGISTRATION IN 1918

The tables thus far described have referred only to the results of *examinations* and to those registered on that basis. Table H, however, shows the total number who received licenses in each state, including those registered by examination, by reciprocity and under various exemption clauses. Altogether, 4,185 physicians were registered by all methods during 1918, as compared with 5,423 in 1917, 5,461 in 1916, 5,872 in 1915, 5,797 in 1914, and 7,865 in 1906. There has been a constant decrease in the totals licensed by all methods until 1915, when there was an increase of 79. The total registered in 1918 was 1,238 less than in 1917, 1,276 less than in 1916, and 1,687 less than in 1915. By reciprocity or under exemption clauses, 1,031 were licensed in 1918, as compared with 1,362 in 1917, 1,338 in 1916, 1,386 in 1915, and 1,427 in 1914. Only four undergraduates were registered during the past year.

TABLE L.—STATE REQUIREMENTS OF PRELIMINARY EDUCATION

* Require a four-year high school education or its equivalent.
† No fixed standard.

There are now forty states which have adopted requirements of preliminary education in addition to a standard four-year high school education. Of this number 32 now require the two year standard. These states, the number of college years required and the time the higher requirements became or become effective are given in the table.

Over 100 were registered by all methods in eleven states, over 200 in four, and over 300 in three, the largest numbers registered being 496 in New York, 392 in Illinois, and 342 in California. Of those licensed in California, 139, or 40.7 per cent., were registered by the endorsement of licenses granted by the boards of other states. California also registered as physicians and surgeons 77 graduates of osteopathic colleges, and 21 osteopaths were so licensed in Colorado.

MEDICAL TRAINING OF APPLICANTS LICENSED IN 1918

Table I is of special interest, since it shows for each state the numbers of candidates coming from medical schools rated in classes A, B and C, thereby indicating the character of the medical training of the candidates licensed during 1918. Of the 4,185 candidates registered, 3,154 were licensed by examination and 1,031 by reciprocity or on presentation of acceptable credentials. Those who graduated prior to 1907, when the first classification of medical colleges was completed by the Council on Medical Education, are included among those graduating from "Miscellaneous Colleges." Of the 3,154 candidates licensed by examination, 2,109, or 66.9 per cent., were from Class A schools; 544, or 17.2 per cent., were from Class B schools; 288, or 9.1 per cent., were from Class C schools, and 213 graduated prior to 1907 or came from foreign colleges. Among the graduates of Class C schools are included 98 graduates of osteopathic colleges who were granted the physician and surgeon's license in California and Colorado. Of the 1,031 candidates licensed by reciprocity, 492, or 47.7 per cent., graduated prior to 1907 and are, therefore, included among miscellaneous or unclassified colleges; 347, or 33.7 per cent., were graduates of Class A medical schools; 138, or 13.4 per cent., were graduates of Class B schools, and 54, or 5.2 per cent., were from Class C schools. Altogether, of the 4,185 candidates registered in 1918, 2,456, or 58.7 per cent., were graduates of Class A medical schools; 682, or 16.3 per cent., were from Class B schools; 342, or 8.2 per cent., were from Class C schools, and for 705, or 16.8 per cent., the colleges are unclassified.

TABLE M.—ADVANCES IN STATE LICENSE REQUIREMENTS IN FOURTEEN YEARS

Requirement or Provision	States Having Provision for			States Still Having No Provision for
	1904	1918	Increase	
Preliminary Education—				
Any requirement	20	46	26	3^{1}
A standard four-year high school education or higher	10	41	31	5^{2}
One year or more of college work	0	40^{3}	32	9^{3}
Two years of college work as a minimum	0	32^{3}	32	17^{3}
That all applicants be graduates of a medical college	36	49	13	0
That all applicants undergo an examination for license	45	48	3	1^{4}
Requirement of practical tests in the license examinations	1	16	15	33
Hospital intern year required	0	8^{5}	8	41
Full authority by board to refuse recognition to low-grade colleges	14	44	30	5^{6}
Boards refusing to recognize low-grade colleges*	5	42	37	7^{7}
Reciprocal relations with other states	27	41	14	8^{8}
Single boards of medical examiners	36	43	7	6^{9}

* In three states, Arkansas, Connecticut and Florida, each of which has three separate boards, only the regular (nonsectarian) boards have refused recognition to low standard medical colleges.

1. District of Columbia, Massachusetts and Wyoming.
2. Idaho, Oregon and the states named in Footnote 1.
3. See Table L.
4. New Mexico.
5. Pennsylvania, 1914; New Jersey, 1916; Alaska, 1917; North Dakota and Rhode Island, 1918; Illinois, 1921, and Michigan, 1922.
6. District of Columbia, Idaho, Massachusetts, Utah and Wyoming.
7. California, Nevada and the states named in Footnote 6.
8. Arizona, Connecticut, Florida, Massachusetts, Montana, Oregon, Rhode Island and Washington. To this list should be added the outlying territories of Alaska, Canal Zone, Philippine Islands and Porto Rico, which have no provision for reciprocity.
9. Multiple boards still remain in Arkansas, Connecticut, District of Columbia, Florida, Louisiana and Maryland.

As will be noted, the largest numbers of Class C graduates were licensed in California, with 116; Missouri, with 52; Arkansas, with 26; Colorado, with 24, and Texas, with 21. All of the Class C graduates registered in Arkansas were licensed by the Eclectic board.

Illinois registered 161 Class B graduates, the largest number, followed by California, with 69; Tennessee, with 58;

New York, with 44, and Arkansas, with 32. Arkansas, California, Oklahoma and Tennessee licensed more graduates of Class B and Class C colleges than of Class A graduates.

Only Class A graduates were registered either by examination or by reciprocity in Mississippi, South Carolina and Vermont.

It is evident that in several states, particularly, more care should be taken in the recognition of medical colleges, or better methods of examination should be adopted which will provide better safeguards against those not having adequate education.

Table J gives those registered without examination on presentation of satisfactory credentials, which included a license issued by some other state. This is commonly referred to as "reciprocity," which conveys the idea that the state which accepts a license of another must be granted the same courtesy by the state issuing the original license. The term does ot always apply, however, since some state boards—Arizona, ifornia, Colorado, Delaware, Maryland, New Hampshire, v Jersey and North Carolina, as examples—accept the ysician's credentials, if satisfactory, whether or not the state board issuing the original license returns the favor. Had not reciprocal relations been established by the thirty-seven states shown in Table J, 972 physicians—many of whom had been in practice for ten or more years—would have been compelled to undergo the ordeal of a second trying examination.

Table K shows in what states were granted the original licenses of those who were registered elsewhere under the reciprocity provision during the last five years. Of the 6,191 physicians licensed through reciprocity during the last five years, the largest number coming from any one state was 874, who obtained their original licenses in Illinois. Although New York has a larger number of medical college graduates each year than Illinois,[2] only 415 physicians obtained original licenses in New York and registered elsewhere through reciprocity in the last five years. This is accounted for by the fact that Illinois has reciprocal relations with twenty-two other states, while New York has established such relations with only seven.

IMPROVED STANDARDS OF LICENSURE

Table L shows the states which have adopted one or two years of college work as a minimum standard of preliminary education for those who seek the license to practice medicine in those states. The first and third columns show, respectively, when the one year and the two years of premedical college work affects students matriculating in medical colleges, and the second and fourth columns give the years in and after which all applicants for licenses in the various states are affected by the increased requirements. This table shows the rapidity with which state board requirements of preliminary education have been advanced since 1908, prior to which no state was requiring more than a four-year high school education. As will be noted, there are now thirty-eight states which have adopted the higher standard, and thirty-two of these require as a minimum *two years* of premedical college work. It is understood that in every instance the one or two years of collegiate work must have included courses in physics, chemistry and biology.

In Table M the advance in standards of licensure is shown for all states since 1904. The most marked increase is in regard to the requirement of collegiate work in thirty-eight states as referred to in Table L. The next greatest increase (thirty-six) is in the number of states—now forty-one—which are refusing to recognize low-grade medical colleges. Although, as shown in the third column, marked improvements have been made in state requirements for licensure, nevertheless, as indicated by the last column, there is still room for further improvement. The greatest needs are for a wider adoption of the requirement of the hospital intern year, the standard of two years of premedical college work, and—a matter of more vital importance—a more general and larger use of practical tests in the examinations. The states in which the boards are making really effective use of such examinations are Illinois, Massachusetts, Minnesota, North Dakota, Ohio and South Dakota. They are being followed to a greater or less extent in a few other states.

NATIONAL BOARD OF MEDICAL EXAMINERS

The National Board of Medical Examiners, which was organized in 1915, consists of fifteen members, including the Surgeon-Generals of the Army, Navy and Public Health Services, and one other representative of each of those services, three representatives of the state medical licensing boards, and six members appointed at large. Up to Dec. 31, 1918, six examinations had been held, as shown in the following tabulation:

Date of Examination	Where Held	Total Examined	Passed	Failed	Percentage Failed
Oct., 1916	Washington	10	5	5	50.0
June, 1917	Washington	12	9	3	33.3
Oct., 1917	Chicago	28	22	6	21.5
Jan., 1918	New York	20	18	2	10.0
Apr., 1918	Ft. Riley; Ft. Oglethorpe	23	18	5	26.1
Dec., 1918	Chicago; New York	16	15	1	6.3
Totals		109	87	22	20.2

Twenty-four medical schools were represented and the results were as follows:

College	Total Examined	Passed	Failed	Percentage Failed
University of California M. S.	1	1	0	0.0
University of Colorado S. of M.	1	1	0	0.0
Howard University Sch. of Med.	1	0	1	100.0
Emory University Sch. of Med.	1	1	0	0.0
Northwestern University M. S.	17	13	4	23.5
Rush Medical College	31	25	6	19.4
Indiana University Sch. of Med.	1	0	1	100.0
State Univ. of Iowa Coll. of Med.	3	2	1	33.3
Johns Hopkins Univ. Med. Dept.	8	6	2	33.3
University of Maryland Sch. of M.	1	1	0	0.0
Boston University School of Med.	1	1	0	0.0
Harvard University Med. School.	6	6	0	0.0
University of Michigan M. Sch.	2	1	1	50.0
University of Minnesota M. Sch.	2	1	1	50.0
University of Nebraska Coll. of M.	1	1	0	0.0
Columbia Univ. Coll. of P. & S.	9	9	0	0.0
Cornell University Med. Coll.	4	4	0	0.0
Univ. & Bell. Hosp. Med. Coll.	1	0	1	100.0
Western Reserve Univ. Sch. of M.	1	1	0	0.0
Jefferson Medical College	2	0	2	100.0
University of Pennsylvania S. of M.	11	10	1	9.1
University of Texas Dept. of Med.	2	2	0	0.0
University of Virginia Dept. of M.	1	1	0	0.0
McGill University Faculty of Med.	1	0	1	100.0
Totals	109	87	22	20.2

Holders of certificates from the National Board of Medical Examiners will be registered without further examination in the following fifteen states:

Colorado
Delaware
Florida
Georgia
Idaho
Iowa
Kentucky
Maryland
New Hampshire
North Carolina
North Dakota
Ohio
Pennsylvania
Rhode Island
Vermont

When the permanence of the National Board of Medical Examiners is established and the high character of its examinations is more generally recognized, it is quite probable that its certificate will be recognized by the licensing boards of a larger number, if not of all states.

IN CONCLUSION

In the gathering and publication of these statistics, the endeavor has been to give a fair presentation of facts, a knowledge of which is always beneficial. This annual presentation of the results of state license examinations has had a powerful influence on medical education and medical licensure in this country. We reiterate our acknowledgments to the state licensing boards for their ready cooperation and the complete reports which have been furnished. For the verification of all figures, the reports and data furnished by medical colleges have been of much value. We have no doubt that the information here published will be of service not only to the medical colleges and to the state boards, but also to the public, since the end-result is better qualified physicians.

STATISTICS OF THE STATE BOARD EXAMINATIONS

Ve publish this week, for the sixteenth consecutive r, statistics based on official reports of examinations iducted by state medical boards, and of registrations reciprocity and other methods. During these six- n years the work has had the hearty support and peration of the executive officers of the various te licensing boards, who have furnished reports of : examinations. Every report has been carefully ked with alumni lists furnished by the deans of medical colleges, and by this cross-checking, errors ve been avoided; and when errors have been dis- vered, the state boards have been notified. Thus, not ly have these statistics been made accurate and iable, but also state board records have been cor- ted. We express our acknowledgments for the lendid cooperation of the officers of both the state ensing boards and the medical colleges by which the blication of these statistics has been made possible.

These statistics throw an important side light on th medical education and medical licensure. For ch state they show the number and character of phy- ians admitted to examinations; the character of the leges from which they graduated; the numbers who re registered and rejected, and the proportion jected. The material is so arranged that the facts garding any one college or any one state can be mpared with those, respectively, of all other colleges d states. Figures show that in some states people e well protected against illiterate and incompetent ysicians, while in others, in varying degrees, the posite situation prevails. A glaring instance relates Arkansas, where, although the regular board of edical examiners is adhering to reasonably high edu- tional standards and methods of licensure, twenty- x physicians were licensed who could not meet its quirements. This was because of the existence of a parate board of eclectic examiners. This board amined twenty-three graduates of a nominally eclec- c medical school, the Kansas City College of Medi- ne and Surgery, and licensed all of them, in face of e fact that this college is not recognized by the licensing boards of Missouri—its home state—and of thirty-four other states. And this has been going on for several years. Indeed, the reports indicate that neither the Arkansas Board of Eclectic Examiners nor the Kansas City College of Medicine and Surgery could exist without the other. It is true that a few graduates of this college were examined also by the Eclectic Board of Connecticut, but they were not so successful in that state in obtaining licenses. Arkansas and Connecticut, meanwhile, are two states which have not yet abolished their separate sectarian boards.

These statistics also call attention to the fact that during the last two years a few boards have examined and licensed osteopaths as physicians and surgeons. The objection to this procedure is not that they are osteopaths, but is based on the serious inferiority of their teaching institutions and their educational qualifications as compared with medical schools and physicians. Osteopathic colleges have been repeatedly inspected and, when measured by the same standards as were applied in the grading of medical schools, no one of them could rank higher than the lowest Class C medical college. Nevertheless, in Colorado, twenty-one osteopaths were licensed as physicians and surgeons by examination, and in Texas eleven were licensed by reciprocity, although the licensing boards of both states have reported that they do not recognize Class C medical schools. Texas also registered three graduates of Class C colleges by examination and seven by reciprocity, although they say they do not admit such graduates to their examinations. In California this year 133 osteopaths were admitted to the examination of physicians and surgeons, and seventy-seven, or about 60 per cent., were granted licenses, including thirty-four who were given merely an "oral, practical or clinical" examination.

When the collection of these statistics was begun by THE JOURNAL in 1903, returns could be obtained from only thirty-seven states, including four from which the returns were incomplete. The records could not be obtained for the other states for the very reason that records were not kept or were too imperfect to enable the boards to supply the information. This condition has been corrected, however, as evidenced by the fact that full and complete reports have been received from all state boards for the past several years.

Since 1905, the collection of the statistics became an important part of the work of the Council on Medical Education in its campaign for the improvement of medical education and licensure. The results in the improvements in medical licensure are set forth in the statistics.[1] Higher standards of preliminary education have been adopted; all states now require that applicants must have graduated from a medical school; all but one state, New Mexico, now require an examination of all applicants; a larger number of states have improved their examination by the use of practical laboratory and clinical tests; a larger number of states have obtained authority to refuse recognition to low-grade medical colleges and are making use of that authority; reciprocal relations between states have been widely extended; eight states require a hospital internship as an essential for the license, and all but a few states now have single boards of medical examiners.

---

[1] Table M, p. 1155.

On medical education the effect of these statistics has been even more pronounced. The attention of medical schools was called at once to the percentages of failures of their graduates at state licensing examinations, and better methods of teaching resulted. A knowledge of the fact that in certain states graduates of various colleges were not eligible for the license unless they had completed two years of collegiate work before entering on the study of medicine, induced a number of medical schools to adopt higher entrance standards which perhaps were not willing to do so voluntarily. The Council on Medical Education has utilized these statistics also in its efforts to improve medical teaching. A classification of institutions based on the percentages of failures coincided quite closely with the first classification prepared by the Council on Medical Education and based on actual inspections. Occasionally an institution obtained a lower percentage than its actual merits warranted, but no institution having a high percentage of failures was found worthy of being included among acceptable medical schools.

Briefly, these statistics show each medical school what improvements are essential if its graduates are to succeed in examinations of state boards; what state boards are requiring as a minimum of preliminary education, and in what states the boards are refusing to examine its graduates. To each state board these statistics show, by comparison with other states, the lines along which further improvements are needed in its educational standards and methods of examination. Constant publicity has led to a general improvement in educational standards and a greater uniformity in the methods of examination by all state boards. The result has been a lessened confusion in the licensing of physicians throughout the country, and correspondingly better safeguards for the public against the licensing of incompetent practitioners.

OBSERVATIONS ON THE FUNCTIONS OF THE BLOOD SERUM PROTEINS

The comparative richness of the serum in proteins is one of the striking facts in regard to the composition of the blood. It seems surprising, therefore, that so little is decisively known regarding the origin and the functions of these proteins in the body. Only a few years ago the most widely accepted view was that the products of protein digestion were regenerated into protein during or immediately after their absorption through the alimentary wall. So long as this belief was entertained, it followed as a logical consequence that the tissue cells were nourished, so far as nitrogenous needs were concerned, from the proteins. In other words, the production of protein was a regular stage in protein assimilation.

The newer knowledge of the chemistry of diges and the phenomena of the absorption of its prod has made the older conclusion untenable. The products of the alimentary digestive processes in case of proteins are amino-acids and, possibly, peptids which enter the circulation as such, pas directly to the tissues without preliminary synthesi protein. The tissue proteins are different from blood proteins. Furthermore, the blood serum teins show minimal, if any, fluctuations during fas or after heavy feeding, a fact suggesting that content in the circulating medium is more or less pendent of the immediate absorption of protein cursors. The fact that the content of proteins in blood maintains a constancy cannot necessarily taken as evidence, however, that the circulating teins are not directly derived from the food pro or play no part in the nutrition of the body cells. content of blood sugar—a substance referable to food intake—is remarkably constant, owing to rapid regulatory transfer that takes place betw food, tissues and blood.

Investigators[1] at the George Williams Hooper Fo dation for Medical Research at the University of C ifornia Medical School have attempted to throw light on the source of the blood serum proteins following their regeneration after plasma depleti By this is meant the withdrawal of whole blood and replacement of the washed red corpuscles suspend in some modification of a protein-free medium physiologic sodium chlorid or Locke's solution. result was that when the plasma proteins were reduced experimentally to a low level (amounting between 20 and 33 per cent. of normal), regenerati was a slow and difficult procedure, often occupyin many days. If such depletion is assumed, as seem reasonable, to be a maximal stimulus for body pr duction of serum protein, it appears from the res quoted that the body can manufacture them only small amounts, even in an emergency. It is true the regeneration is somewhat more rapid and com on a meat or mixed diet, as compared with fa But, as the California investigators remark, wh follow the slow regeneration to normal in from ten days on a meat diet, we are fairly certain that blood serum proteins cannot be actively concern transition products of protein metabolism between food proteins and body tissue proteins;

---

[1] Kerr, W. J.; Hurwitz, S. H., and Whipple, G. H.: Reg Blood Serum Proteins, I, Influence of Fasting on Cur Regeneration Following Plasma Depletion, Am. J. Physiol. 47 II, Influence of Diet on Curve of Protein Regenera Plasma Depletion, ibid. p. 370; III, Liver Injury Alone; L and Plasma Depletion: the Eck Fistula Combined with tion, ibid. p. 379.

the return to normal would be expected to take ce within twenty-four hours or less.

ince these experiments give no evidence that the proteins may be in any way concerned as interdiary products between food protein and body tissue parenchyma protein, it is logical to inquire anew as the function of the serum proteins. Accumulating indicate that it is independent of the nitrogenous bolism of the body. The blood serum protein exhibits a remarkable stability even under unusual litions of both health and disease. The experital evidence acquired by Kerr, Hurwitz and Whip points to the liver as concerned in maintaining the rmal level, just as this organ has been implicated, d apparently with good reason, in the production of fibrinogen of the blood. If we add that the blood rum proteins probably assist in maintaining a desired cosity of the blood and in preserving its neutrality, remove them from the domain of nutrition into the alm of conjecture. Here lies a *problem* for the ture.

THE FOXHALL FOSSIL HUMAN JAWBONE

In our Correspondence Department this week we blish a letter from J. Reid Moir of Ipswich, Engd, in regard to a fossil human jawbone found at xhall. As will be noticed, the object of Mr. Moir's nmunication to THE JOURNAL is to secure, if possi-, some trace of the jawbone, which Mr. Moir ieves to be in the United States. While not strictly lical, the subject of the antiquity of man, as revealed fossil fragments such as this, is of special interest most physicians. Prof. Frederick Starr of the partment of Anthropology of the University of cago is inclined to believe that this fragment proby is not of the Pliocene period.

he jawbone mentioned in Mr. Moir's letter caused siderable talk a half century ago. It is said to have n found in "coprolite" digging at Foxhall, near wich, Suffolk, in 1855. It came into Dr. Collyer's ds and was shown by him at a meeting of the nological Society at London in 1863. The famous ntists of the day examined it—Owen, Huxley, rchison, Lyell, Busk. It was probably the jawbone a woman well on in years. While admitting that it wed some curious features, none of these authori gave special significance to the piece, and its iquity was clouded. Collyer published an article h illustration in the *Anthropological Review* of 7. His account leaves serious doubt as to the cirstances of its finding; his picture shows that the presents a pronounced chin eminence, a "modern" acter, absent in the old Heidelberg and Neandertypes, though present in Chancelade-Cro-Magnon. skeleton has recently been found, near Ipswich, r chalky boulder clay. Instead of presenting the nderthal type, it is "modern." A long article in the *Journal* of the Royal Anthropological Institute for 1911 discusses the find in detail. Dr. Arthur Keith has made a careful anatomic examination. The individual was about 5 feet 10 inches in height, had a brain of modern form and size, and relatively small jaws and teeth, "and all the features so like the men who live in England today that it seems impossible that a form which lived before the deposition of the chalky boulder-clay could have come down to modern times so little changed." It is this find and others of similar bearing that give present interest to this "coprolite jaw" of Dr. Collyer, for which search is being made. Do these recent finds, and the lost jaw, prove that a "modern type" of man, a *Homo sapiens*, has lived so long? We would expect "missing links" only—"intermediate forms"—so far back in time. To find a "modern type" here is serious. In the course of his discussion, Keith says:

> It will thus be seen that the Ipswich skeleton is not an isolated discovery. It is one of a great number, which to my mind clearly indicates that we have to seek for the evolution of the modern type of man—not in the Pleistocene (i. e., glacial) but *in the Pliocene formations*. With the evidence derived from the discovery of the human remains, the discovery of worked flints[1] must also be taken into account.

Professor Starr states that the three oldest specimens of human remains now recognized by science are those found at Trinil in Java, at (near) Heidelberg in Germany and at Piltdown in England. The Java fragments were described under the name of *Pithecanthropus*, and the type was considered a veritable "missing link." The Heidelberg jaw was unquestionably human, but notable for size, thickness and other characters. The find at Piltdown was the upper part of a skull of interestingly low type. The latest writers—like Osborn and Keith—consider all of these actually "human," but refer them to species different from *Homo sapiens*, to which all existing men belong. All of them show striking brute characters and accord well with what evolution suggests as to ancient types. All are of "glacial" age; Osborn, who is conservative in estimates, refers the Piltdown skull to the third interglacial stage (perhaps 100,000 years ago), the Heidelberg jaw to the second interglacial stage (perhaps 200,000 years ago), and the Trinil fragments to the first interglacial stage (perhaps 475,000 years ago). Osborn estimates the entire glacial period at 525,000 years. Back of it comes the Tertiary Age of the geologist, with the Pliocene as its closing period.

Apart from "eoliths," about which discussion now rages, no relics of human handiwork are recognized as older than the third interglacial stage. The rudest intentionally shaped implements and weapons known come from its gravels and other deposits. The oldest of them are perhaps 125,000 years old. We have no artefacts made by Heidelberg man or *Pithecanthropus*. These creatures may have used natural splinters of flint—"eoliths"—but we do not *know*. In the glacial deposits from the third interglacial stage onward remains of human beings—skullcaps, jawbones, other fragments, even complete skeletons—have been found. At least three types of men are represented during glacial times—Neanderthal (low and perhaps related with Trinil, Heidelberg and Piltdown), Chancelade-Cro-Magnon (much higher, with headform and body structure quite comparable with *Homo sapiens* and no doubt related to him) and Grimaldi (also of *Homo sapiens*, but distinctly "negroid," African in character). All three are "glacial," the Cro-Magnon and Grimaldi from relatively late glacial deposits, the Neanderthal from earlier. Still, the Neanderthal certainly lasted on until these more modern types had made their appearance.

---

[1] These are claimed by their finder, the same Mr. Moir, as Pliocene; they are probably "eoliths," not intentionally shaped.

But—to return to the present—let it be remembered that the Foxhall human jaw bone is possibly somewhere in this country and that the immediate object is to find it.

THE FOOD CRISIS IN GERMANY

When Germany began to realize her isolation as the result of the blockade, she loudly proclaimed the impossibility of success in the direction of an "Aushungerungsplan"—a scheme to deprive her of indispensable food supplies. There is no occasion at present to assume that there was any pronounced impairment of health on the part of the population of the Central Empires because of food shortage in the earlier months of the great struggle. Accumulated resources were still available, and neighboring neutrals were willing and able to exchange food products for money or commodities. As the months of fighting passed into years, however, the need of strict rationing of the population became an open secret. Lack of fats was freely admitted. It was openly attested that thousands of civilians were declining in body weight; yet this was ostensibly hailed as a symptom favorable rather than otherwise to well being. The doctrine of "physiologic economy in nutrition" was preached with seemingly timely emphasis on its alleged advantages to health.

A prolonged period of enforced privation has given an exceptional opportunity to test the validity of some of the prophesies, and to learn what rations kept scant, far beyond the expectation of those who participated in them, really mean for great masses of people. During our own days of conservation, the possible distinction between prudent living and reduced food supply was not always kept clear. Overweight may well represent an unfavorable life insurance risk; yet this fact does not place the stamp of wisdom on underfeeding.

Among the reputed benefits besides the reduction of undesirable corpulence ascribed to the strict rationing of the German population were reports of reduction in gastro-intestinal disorders owing to more frugal living. The decrease in meat consumption was said to have caused gout to disappear almost completely. Such consequences might well be hailed as personal advantages. However, the veil of strict censorship behind which the internal affairs of Germany have long been hidden is now being lifted. Professor Rubner of Berlin, who has long been a student of the nutrition of the people, has recently pictured the state of affairs as he saw them.[1] He has proclaimed that the dangers threatening Germany were at first utterly underestimated. The awakening came with the never-ending restrictions in the allowance of food, which grew scantier as time progressed until every one began to realize through his own deprivation what the blockade really signified. The securing of provisions from friendly or conquered states proved, says Rubner, to be like a drop of water on a hot stone. The turning point in nutrition came in the middle of 1916. From that time on, the people were deprived of the important foods, or could secure at most only small quantities. Meat, eggs, milk and butter practically disappeared, with the result that the guaranteed portion for the adult was ultimately reduced to one half or even one third of the former allowance. The year 1918 brought no halt along the road to decline; on the contrary, it necessitated a further restriction of meat, and renewed decrease in the milk allowance for children and invalids.

Current Comment

TESTING A PHYSICIAN'S QUALIFICATIONS FOR PRACTICE

The scheme generally adopted in this country to ascertain whether a physician is properly qualified to practice medicine is duplex in character. It requires, first, that the applicant submit evidence of graduation from a "reputable" or "recognized" medical school; and, second, that he pass a state examination. The reputability of a medical school may be judged by an investigation of its admission requirements; the manner in which these requirements are enforced; the qualifications of its teachers; the character of the teaching methods and of the facilities for teaching—in brief, the equipment and facilities of the college for furnishing a training in accordance with present-day medical knowledge. Graduation from a recognized or reputable medical school is evidence that the applicant's medical training is complete, and implies that the faculty of the medical school considers him qualified to practice medicine. In effect, therefore, the examination is a supplementary test of the candidate's fitness to practice, and is not of vital importance in states in which only graduates of high grade medical schools are examined.

---

[1] The facts here reported are quoted from the Berliner klinische Wochenschrift, Jan. 6, 1919, p. 2.

But in those states in which this is not the case, the examination becomes of extreme importance, and should be made especially thorough, since here it is the sole means of deciding whether or not the candidate is qualified to treat the sick.

REGISTERING OSTEOPATHS AS PHYSICIANS AND SURGEONS

As shown elsewhere this week, the licensing boards of three states not only have admitted graduates of osteopathic colleges to the examinations for physicians and surgeons, but also have licensed a decidedly generous proportion of them. It is interesting to note that in these three states osteopaths have been appointed as members of the medical licensing boards, California and Texas each having two such members and Colorado one. There is no objection to admitting osteopaths to the physicians and surgeons' examination if the test of their qualifications is fully equal to that for physicians and surgeons. But such is not the case. While they may be examined, they are not required to be graduates of any medical school, much less one that is recognized. Neither is the examination of such character as to test their knowledge of and ability to use scientific methods of diagnosis, much less of the prevention and treatment of disease. It is well known that osteopathic colleges do not enforce as high requirements for admission, nor possess as well equipped laboratories, nor have teachers as efficiently trained in scientific medicine as even Class C medical schools, much less those in Classes B and A. As a matter of fact, two of the states, Colorado and Texas, refuse to recognize Class C medical schools, but do admit graduates of osteopathic schools to the examination for physicians. To ascertain the competence of such candidates to practice as physicians, the duplex method of licensure referred to in the preceding comment should be adhered to. If osteopaths wish to limit themselves to their peculiar and restrictive form of treatment, let them appear before the public in their true light; if they want to appear before the public as physicians and surgeons and to assume all the responsibilities as such, let them be measured by the same standards and submit to the same tests.

LOW TYPHOID RATE IN RICHMOND

We learn from the Richmond authorities that, owing to an error in transcription in the health office in that city, an incorrect figure for the number of deaths was sent The Journal, so that the 1918 rate for Richmond should be 7.5 instead of the high figure given in the annual report for 1918. We make this correction with the greater pleasure since in the past few years Richmond has made great efforts to reduce its typhoid rate, and has succeeded better than any other Southern city. This is the second successive year in which the rate has remained remarkably low, and we congratulate that city on its admirable record. We regret the error in the annual summary, but it is plainly impossible for The Journal to go back of the figures sent it and make a special investigation in each case. Those conversant with the local situation in certain cities are sometimes critical of the figures presented in The Journal. We have, for instance, received a number of intimations that the very low typhoid rate reported for one of our great cities in the past three years does not quite reflect true conditions in that city. It is not believed, however, that it is the province of The Journal to go behind the figures sent it by official agencies. For one thing, the necessity for promptness in publication would forbid any attempt at special investigation in particular cases. None the less, we regret that Richmond, a city with such an excellent typhoid record, should have suffered by a clerical error, although it was none of The Journal's making. We gladly repeat our statement about Richmond in the sixth annual report (for 1917): "Typhoid reduction in the past ten years reflects great credit on the health administration."

THE WALLINGFORD OF MUS MUSCULUS

"One thousand mice in a year should return $25,000," says the Laboratory Supply Company of Philadelphia. A further reading of the pamphlet in which this statement occurs discloses that an outfit consisting of three female mice, one male, and a hutch completely equipped, together with a book of instructions, can be had from the Laboratory Supply Company—for $10. This outfit should yield, by the laws of nature, fifteen litters a year, or 300 new mice, worth $75. As one of the testimonials in the booklet puts it: "Mice are certainly some breeders. Can hardly stop them after they get started." Allowing $5 for expense, since mice eat very little, we have $60 profit, or 600 per cent., on the original $10 investment. This attractive proposition is exceeded only by the cat and mouse farm of proverbial fame. In introducing the general subject the Laboratory Supply Company informs us that:

> Because of the extreme shortage of white mice thousands of men, women and children, as well as our soldiers, died during the last year. Many of these deaths, in fact a large percentage of them, could have been averted had mice been available.

Then we read in a letter accompanying the booklet the following important scientific statement:

> Spanish influenza antitoxine would have greatly retarded the spread of that terrible disease and would have saved thousands of lives, but enough small animals were not available to make the antitoxine in sufficiently large quantities. In making the different antitoxines some small animals are absolutely needed to prepare, test and standardize the antitoxine. No antitoxine can be used before it is properly tested and standardized. Guinea Pigs are used to test and standardize the different fever antitoxines such as scarlet, typhoid and diphtheria, while White Mice are used for pneumonia and influenza antitoxines.

The pamphlet and letter from which the quotations are taken evidently have been received by many physicians, since many were forwarded to The Journal. Physicians do not appear to have fallen for this investment to any great extent. Of course, to any one familiar with laboratory methods or with modern medical practice, the absurdity of the claims is apparent. White mice are used only to a limited extent in immunologic, experimental work, and beyond this primarily for typing pneumococci and streptococci. Furthermore, there exist methods for typing pneumococci without the use of laboratory animals. The statement of the Laboratory Supply Company that the demand for white mice is enormous and that "there are enormous profits for each of those who respond to this appeal" are not in accord with the facts. Their offer to accept war bonds and war savings stamps in return for breeding outfits is on a par with similar offers by promoters of dubious speculations.

WATER-BORNE TYPHOID STILL OCCURS

The recent water-borne typhoid outbreak in Herkimer, N. Y.,[1] affords another illustration of the importance of controlling and safeguarding water purification by chlorination. It cannot be emphasized too often, first, that some waters are much more difficult than others to treat by the chlorination process, and secondly, that it is not safe to entrust the supervision of any water chlorination to unskilled subordinates. The hand of a responsible expert must be kept on the operation all the time. Jordan and Irons[2] have shown in their report on a typhoid outbreak at Quincy, Ill., how well-intentioned deviations in the amount of chlorin applied might result disastrously. There is other evidence to the same effect, notably in an outbreak in Milwaukee in 1916. As regards the Herkimer epidemic mentioned above, we read that an emergency supply was resorted to in time of water scarcity, and that "while an attempt was made to sterilize this emergency supply by means of liquid chlorin, the arrangement of the apparatus was such that the chlorin was not properly applied." As a result of this and further omission of and interference with the chlorination process, contaminated creek water gave rise to about 155 cases of typhoid. It must be repeated that water purification is not an automatic affair and does not function without guidance. Especially must highly contaminated water be very cautiously dealt with if dependence is placed on chlorination.

THE GOLDENROD AND HAY-FEVER

With the recurrence of the hay-fever seasons, physicians will be interrogated as usual regarding the "dangers of flowers" and other alleged noxious factors popularly supposed either to contribute to the distress of hay-fever victims or to threaten the unattacked. The knowledge that plants play a decisive part in the etiology of the disease has become widespread. Nevertheless a wider appreciation of the origin of the pollens for which a relationship to hay-fever seems to be established ought to be encouraged. Scheppegrell[3] has formulated the following characteristics of hay-fever plants: They are wind pollinated, are very numerous, the flowers are inconspicuous, without bright color or scent, and the pollen is formed in great quantities. In the spring season now at hand the chief offenders are the pollens of grasses in all sections. The fall hay-fever in the Northern, Eastern and Southern states[4] is for the most part attributed to the pollens of the ragweeds (*Ambrosiaceae*), these being replaced in the Pacific and Rocky Mountain states by the wormwoods (artemisias). Scheppegrell[5] seems to have proved an alibi for goldenrod. Its flowers are insect pollinated, have bright colors and scent, and the pollen is not formed in large quantities. In fact, according to Scheppegrell, it is never found on atmospheric pollen plates. Furthermore, goldenrod continues to bloom for some time after the close of the hay-fever season. It will be hard to convince many victims of the disease that Scheppegrell is correct in his views regarding the goldenrod; but if these observations are confirmed, a beautiful flower will be saved from undeserved disrepute.

Association News

THE ATLANTIC CITY SESSION

Tournament to Be Held by the American Medical Golfing Association

The American Medical Golfing Association will hold its 1919 Tournament, June 9, on the links of the Atlantic City Country Club. Luncheon will be served at the club house from 12 to 2, and the annual golf dinner and meeting of the association will be held that evening. The tournament will be conducted in a manner similar to that followed last year. Section captains will be appointed and will be expected to get out their respective teams. Entries will be made in the order of their receipt, and each team will be closed when the capacity of the course (twenty-five foursomes) is reached. They will be closed at the office of the secretary, under any conditions, May 30.

Fellows desiring to be entered will appreciate how important it is for the Atlantic City Committee on Arrangements to know as early as possible the number that will participate. Accordingly, Fellows are urged to be entered and to inform their golfing confrères of this tournament, that they also may submit applications as promptly as possible.

Any Fellow of the American Medical Association becomes automatically a fellow of this association on acceptance of its by-laws and the payment of the enrolment fee ($2). This enrolment fee is for the general funds of the association and may be paid at any time.

Those desiring further information should address Dr. Will Walter, Secretary-Treasurer, 1414 Chicago Avenue, Evanston, Ill.

Ample Hotel Accommodations Assured

The Local Committee on Arrangements assures those who plan to attend the coming annual session — the Victory Meeting — of the Association, to be held in Atlantic City next June, that there are ample and excellent hotel facilities at reasonable rates available for all. The chairman of the Subcommittee on Hotels, Dr. David B. Allman, or the chairman of the Central Local Co on Arrangements, Dr. Emery Marvel, will gla llows in communication with hotel managers. located on the avenues indicated, off the American plan at rates for a sing

Medical Mobilization and the War

Personnel of the Medical Corps

For the week ending April 11, the Medical Corps contained 19,008 officers, a decrease of 310 from the previous week. The Medical Reserve Corps contained 1,555 officers. The total number of medical officers discharged since the beginning of the war is 14,533.

Distinguished Service Cross to Gen. T. H. J. C. Goodwin

The commander in chief of the American Expeditionary Forces announces that pursuant to authority granted by cable A-2830 he has awarded the Distinguished Service Cross to Lieut.-Gen. Sir T. H. J. C. Goodwin, G.C.B., C.M.G., director-general, army medical service. It will be remembered that General Goodwin was sent to this country as liaison officer, following the entrance of this country into the war, and spoke before many medical organizations.

The Recall Appears

The first issue of the *Fort Sheridan Recall*, a newspaper issued for the benefit of the wounded at General Hospitals Nos. 28, Fort Sheridan, and 32, Chicago, appeared, April 9. The new journal is similar to those already in operation in Washington, New York and Detroit, and contains news of the various hospitals in the Central Department. A printing plant is being installed at Fort Sheridan so that patients in U. S. General Hospital No. 28 may learn the printing and allied trades.

Courses for Student Nurses at Civilian Hospitals

Arrangements are being made by the Surgeon-General of the Army with civilian hospitals for courses of instruction for student nurses. To be eligible for the diploma of the Army School of Nursing, students must complete the courses satisfactorily in both classes of hospitals. The arrangements with the civilian hospital training schools provide that the students in the Army School of Nursing shall be given board, lodging, laundry and such allowance, if any, as is given their own students. Some schools do not provide an allowance. During the period of their affiliation the monthly allowance of $15 from the Army will be discontinued.

Weekly Bulletin, A. E. F.

(*March 17, 1919*)

HIGH DIPHTHERIA INCIDENCE AND DEATH RATE

This number of the *Bulletin* is devoted largely to two epidemics of diphtheria occurring in Base Section 2 and in Base Hospital No. 54. In Base Section 2 there were 166 cases. In summarizing conditions, the chief surgeon states that the late diagnosis due to indifferent examination and lack of pains to obtain confirmatory cultures, failure to give antitoxin promptly on clinical diagnosis and have the diagnosis confirmed later, insufficient initial dose and unsuitable use of small divided doses seem to have been chiefly responsible for the deaths. It is stated that of 96 cases in which full reports were made, 56 developed so long after admission to hospital that it is probable the infection was acquired in the hospital.

WEEKLY REVIEW

The venereal disease rate has dropped to 30.97 from 36.69, due to substantial reductions in the rates in all sections and districts, except Base Sections 4 and 6 and in the First and Third Armies, where increases were recorded. Apparently this reduction is largely due to decreased exposures, since the percentage of failures to take prophylaxis is higher than it was a week ago.

There have been reductions during the past week in all communicable diseases, except paratyphoid fever. One case of smallpox was recorded in the Second Army. The total number of communicable diseases reported during the week is less than at any time since the signing of the armistice.

Interallied Congress of Aviation Medicine

Rome, Feb. 15-19, 1919

An interallied congress of aviation medicine convened in Rome, February 15 to 19, inclusive. The various countries concerned were thus represented:

Great Britain: Lieut.-Col. Martin Flack, R. A. F. M. C.; Dr. Henry Head; Lieut.-Col. Georges Dreyer, R. A. M. C.; Lieut.-Col. Birley, R. A. F. M. C. (absent through illness); Capt. D. Ranken, R. A. F. M. C. (interpreter).

France: Capt. Georges Guillain; Capt. J. LeMaire; Lieut. L. Ambard; Lieut. D. Garsaux; Lieut. R. Gaumont, artillery observer, secretary.

Italy: Major-Gen. R. Bressanin; Lieut.-Col. C. Gradenigo; Lieut.-Col. Arturo Cascarino; Major Amedo Herlitzka; Major Alberto Agazzotti; Prof. Gino Galeotti.

Belgium: Capt. P. Voncken, Service de santé.

United States: Col. Thomas R. Boggs, M. C.; Col. W. H. Wilmer, M. C. (absent through illness); Lieut.-Col. L. G. Rowntree, M.C.

Captain Samarini, American Red Cross, acted as interpreter. Professor Gradenigo of Italy was elected president of the congress.

SUBJECTS DISCUSSED

The program was arranged by the Italian delegation. The following subjects were discussed:

1. Considerations concerning the admission of candidates as pilots: (*a*) The necessity of the psychophysiologic examination and its organization. Great importance was attached to the question of civil and commercial aviation. In order to secure pilots physically and temperamentally fit it was deemed advisable to have psychophysiologic examinations for all candidates for aviation, military or civil. Perfect somatic health should be insisted on, and if possible perfect sensory functions. Absolute physical fitness should be demanded of all civil pilots, while for military aviation each country must determine the limits for admission according to its necessity. It was generally agreed that simple psychomotor tests alone are of little consequence, but that discrimination tests are of greater value in determining aptitude for flying. Reaction time tests alone should not, however, constitute the basis for rejection, but they should constitute a part of the general examination of the candidate. (*b*) Indispensable tests at the present moment of our knowledge of the physiology of aviation. This and the following subject were discussed at length; the more important conclusions are presented later. (*c*) Limits of fitness and causes for exclusion. (*d*) The necessity for continuing in the proper institutes the studies and researches in physiology and hygiene of aviation. (*e*) The need of special training in psychologic institutes of medical officers attached to aviation. The last two subjects, *d* and *e*, were unanimously granted.

2. Duration of fitness: (*a*) Necessity of periodic examination of pilot. This was unanimously admitted. (*b*) Necessity of periods of rest. The necessity was admitted by all. It was deemed advisable to leave the question of time duration to the physician in charge of the fliers rather than make it a matter of routine as suggested by the Italians, who advocated one month's rest after each 100 hours of flying. (*c*) The special trouble of aviators.

3. Methods for the protection of the pilots: (*a*) Protection against cold and wind. Those with experience felt that

electrically heated clothing had proved a failure. Fur lined clothing has proved much more popular with the pilots themselves. Face greases were in general use in all the countries and were considered of unquestionable value, but further experimentation is necessary in regard to composition. Belts and padding for the cockpit were also discussed. (*b*) Means of controlling the effects of low barometric pressure. It was deemed essential to equip all machines with an oxygen apparatus preferably automatic in character. No decison was reached as to whether carbon dioxid is nesessary in addition. (*c*) General hygienic considerations.

4. Medical organization and medicolegal responsibility.
5. Representation to the governments concerned.

SPECIAL SESSION

A special session was held on the day following the official congress for consideration of some of the problems fundamentally important in aviation medicine, such as circulation, respiration, vision and equilibrium.

Circulation: In order to obtain comparable results in various countries, uniformity in blood pressure apparatus and in technic regarding posture and type of exercise was advocated in the study of the effects of posture and exercise on the pulse and blood pressure.

Respiration: Studies of vital capacity were considered by the British of definite value, especially in relation to fatigue. It was suggested that hereafter it be not considered alone but in relation to body surface. Colonel Dreyer asserted that vital capacity is a function of a body surface rather than that of body weight, and submitted a practical formula in this connection. Flack's test (a support of a 40 mm. column of mercury) was looked on as an excellent index of physical fitness and was considered of special value in revealing flying fatigue.

Vision: The desirability of perfect vision is unanimously admitted. America alone was in a position to demand perfect vision without correction by glasses. It was left to each country to set its limits as determined by its needs and the supply of men available. The importance of muscle balance and of color vision was emphasized. A general feeling existed that there was need of further study of standards in relation to night vision.

Equilibrium: While it was agreed that vestibular function has some bearing on aptitute for flying, it was felt that its importance had been overemphasized. It was the opinion of the congress that much further study was necessary before limits could be placed on the various Bárány chair tests.

RESOLUTIONS

Resolutions were passed that:

1. Special examinations are necessary for aviation. The basis of this should be a thorough general physical examination. Perfect somatic health is essential and in addition, if possible, perfect sensory functions.
2. Research institutions for medical, physiologic, psychologic and hygienic investigations are essential. Such institutions should be maintained in each country.
3. It is desirable that such institutes should be uniformily known as aviation medicophysiologic institutes.
4. Uniformity is desirable in relation to standards in medical, physiologic, psychologic and hygienic examinations as carried on in various countries.
5. Special training is necessary for medical officers designated for service in aviation, and provision for their training should be made in the aviation medicophysiologic institutes.
6. All aviation medical officers attached to field work should be required to fly as passengers, and it is desirable that medical officers engaged in research problems of aviation should also fly as passengers in order that they may better grasp the flier's point of view of the problems involved.
7. Special hospitals should be established or wards under proper control should be set aside for military fliers in existing hospitals, and such hospitals should be supplied with properly equipped laboratories for the studies in relation to aviation medicine.
8. It is essential to equip all machines with an apparatus, preferably automatic in character, for the administration of oxygen and carbon dioxid in order to overcome the effects of altitude.
9. A permanent organization should exist for the prosecution of work in relation to aviation medicine and for the interchange of ideas and information relating to it.

OFFICERS

A permanent organization was created and designated as the Société scientifique d'étude médicale aeronautique. The following officers were elected: president, Dr. Georges Guillain, Paris; secretary, Dr. Alberto Agazzotti, Modena, Italy; treasurer, M. Raymond Gaumont, Paris. Executive committee: Dr. Giuseppe Gradenigo for Italy; Dr. Henry Head for Great Britain; Dr. Thomas R. Boggs for the United States; Dr. Jules Voncken for Belgium. Rome was selected as the home of the society, and Oxford, England, for the next annual meeting in 1820.

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

To Chicago, Ill., from Lakewood, Capt. R. J. E. ODEN, Minneapolis.

To Walter Reed General Hospital, D. C., from Camp Lee, Lieut. C. K. HOLMES, St. Paul. For instruction, and on completion *to his proper station*, from Fort McPherson, Lieut. S. V. HODGE, Minneapolis.

The following order has been revoked: *To San Diego, Calif.*, Rockwell Field, from Riverside, Lieut. R. A. JOHNSON, Minneapolis.

Missouri

To Camp Jackson, S. C., base hospital, from Dansville, Capt. W. T. PATTERSON, Shelbina.

To Camp Zachary Taylor, Ky., base hospital, from Camp Shelby, Capt. E. L. DORSETT, St. Louis.

To Fort McHenry, Md., from Camp Dix, Lieut.-Col. W. T. COUGHLIN, St. Louis.

To San Francisco, Calif., Letterman General Hospital, from Fort Oglethorpe, Lieut. W. S. CULPEPPER, Willow Springs.

To St. Louis, Mo., from Fort McHenry, Lieut.-Col. W. T. COUGHLIN, St. Louis.

Nebraska

To report to the commanding general, Western Department, from Vancouver Barracks, Lieut. W. E. MOGAN, Petersburg.

New York

To Camp Dodge, Iowa, base hospital, from Camp Dix, Major H. A. DURHAM, New York.

To Camp Upton, N. Y., base hospital, from Camp Dix, Capt. J. J. PARSONS, Cortland.

To Camp Lewis, Wash., base hospital, from Camp Fremont, Capt. E. M. JOHNSON, New York.

To Camp Meade, Md., to examine the command for cardiovascular diseases, from Camp Sevier, Lieut. M. A. McIVER, New York.

To Camp Meigs, D. C., to examine the command for nervous and mental diseases, from Camp Dix, Capt. W. M. KRAUS, New York.

To Camp Pike, Ark., base hospital, from Camp Gordon, Major F. G. HODGSON, Elmira.

To Camp Upton, N. Y., base hospital, from Camp Dix, Capt. C. M. ALLABEN, Roscoe; from Hoboken, Lieut. E. A. SPIES, New York.

To Eastview, N. Y., from Camp Upton, Major C. E. COON, Syracuse; from Walter Reed General Hospital, Lieut. S. EPSTEIN, New York.

To Fort Logan H. Roots, Ark., from Camp Travis, Lieut. A. RAVICH, Brooklyn.

To Walter Reed General Hospital, D. C., for instruction, and on completion *to his proper station*, from Camp Upton Lieut. F. S. WETHERELL, Syracuse; from Fort Benjamin Harrison, Lieut. J. G. MORRISEY, Yonkers; from Fox Hills, Capt. L. H. FINCH, Amsterdam.

The following orders have been revoked: *To Camp Meade, Md.*, base *hospital*, from Fort Oglethorpe, Capt. H. R. WILLSE, Westfield. *To Fort McPherson, Ga.*, from San Juan, Major E. W. LEE, New York.

North Dakota

To Fort Sheridan, Ill., from Camp Dix, Capt. J. A. HALGRON, Bismarck.

Ohio

To Colonia, N. J., from Camp Dix, Major P. D. WILSON, Columbus.

To East Potomac Park, D. C., from Army Medical School, Lieut. F. BEEKEL, Cleveland.

To Fort McHenry, Md., from Camp Dix, Lieut. F. F. DAVIS, East Liverpool.

To Fort Sill, Okla., Post Field, from Fairfield, Ohio, Lieut. E. I. G. REINARTZ.

To St. Louis, Mo., from Camp Dix, Major P. G. BORDEN, Massillon.

To Washington, D. C., Surgeon-General's Office, and on completion *to Colonia, N. J.*, from Camp Dix, Major P. D. WILSON, Columbus.

Oregon

To Cape May, N. J., from Surgeon-General's Office, Capt. L. SELLING, Portland.

To San Francisco, Calif., Letterman General Hospital, from Camp Lewis, Capt. F. J. ZIEGLER, Portland.

Pennsylvania

To Camp Wadsworth, S. C., from Camp Jackson, Lieut. L. G. FLANNERY, Philadelphia.

To Cape May, N. J., from Camp Dix, Lieut. W. R. KRAUSS, Philadelphia.

To Fort Bliss, Texas, base hospital, from San Diego, Major A. W. YALE, Philadelphia.

To Fort McPherson, Ga., from Washington, D. C., Lieut. C. H. MANLOVE, Jr., Altoona.

To Fort Snelling, Minn., for consultation, and on completion *to Cape May, N. J.*, from Rochester, Minn., Major C. H. FRAZIER, Philadelphia.

To Otisville, N. Y., from Mineola, Col. A. J. SMITH, Philadelphia.

To Philadelphia, Pa., from Camp Upton, Lieut. P. A. LONERGAN, Dickson City.

To Walter Reed General Hospital, D. C., for instruction, and on completion *to his proper station*, from Carlisle, Major D. M. W. GRANT; from Lakewood, Capt. W. P. HUGHES, Pittsburgh.

To Washington, D. C., from Camp Dix, Lieut. L. W. HUGHES, Tioga. Surgeon-General's Office, from Camp Crane, Lieut.-Col. R. SLEE, Swiftwater.

The following order has been revoked: *To Cape May, N. J.*, from Camp Dix, Lieut. W. R. KRAUSS, Philadelphia.

South Dakota

To Fort Snelling, Minn., from Camp Lewis, Lieut. D. SUTTON, Redfield.

Tennessee

To Camp Gordon, Ga., from Camp Dodge, Lieut. M. E. CANNON, Riceville.

Texas

To Belleville, Ill., Scott Field, from Detroit, Capt. W. R. RUSSELL, Ben Hur.

To Camp Bowie, Texas, base hospital, from Camp Dix, Capt. G. W. DAY, Fort Worth.

To Fort Douglas, Utah, from Houston, Capt. O. P. GOODWIN, Lamasco.

To Fort McHenry, Md., from Camp Dix, Lieut. J. R. WHISENANT, San Antonio.

To Fort McPherson, Ga., from Camp Bowie, Lieut. D. C. BURKES, San Antonio.

To Fort Sam Houston, Texas, base hospital, from Camp Bowie, Major J. H. GAMBRELL, Dallas; from Camp Dix, Lieut. F. N. HAGGARD, San Antonio.

To Fort Sill, Okla., Post Field, from Dallas, Lieut. S. G. ODOM; from Millington, Lieut. G. P. RAWLS, San Augustine.

To Fox Hills, N. Y., from Camp MacArthur, Lieut.-Col. S. W. FRENCH.

To Houston, Texas, Ellington Field, from Camp John Wise, Major A. M. LEHMAN.

To San Antonio, Texas, Kelly Field, from Dallas, Capt. L. G. BUCHANAN, Big Springs.

Utah

To Camp Meade, Md., from Long Beach, Capt. H. B. FORBES, Ogden.

Virginia

To Camp Meade, Md., to examine the command for nervous and mental diseases, from Camp Lee, Lieut. J. A. STRICKLAND, Norfolk.

To Fort Sheridan, Ill., from Camp Custer, Capt. C. W. MERCER, Richmond.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Radium and Oncologic Institute.—Through the interest of Mr. King C. Gillette, the Radium and Oncologic Institute has been established in Los Angeles, and a fireproof building, to cost about $65,000, is now under construction. The building will contain laboratories for clinical research work, and has a modern and complete roentgen-ray equipment and more than 1 gm. of radium with the necessary emanation apparatus and appliances. The institution will afford, for a fee consistent with the financial condition of the patient, treatment of neoplastic diseases. Profits earned above those required for the expense and maintenance of the institution will be devoted to scientific and research work. Dr. Rex D. Duncan, Los Angeles, has been selected as medical director and will be assisted by a resident staff consisting of a pathologist, roentgenologist, physicist, and other necessary assistants. The institution will be ready for operation early in August.

ILLINOIS

New Hospital in Rock Island.—The new St. Anthony's Hospital, Rock Island, is almost completed and will be ready to receive patients early in June. The new building has been constructed at a cost of about $240,000, is five stories in height, fireproof and contains 150 rooms.

Institute of Medicine to Discuss Reconstruction.—At its meeting of April 19, held at the City Club at 8 p. m., the Institute of Medicine will discuss "Reconstruction." Col. Frank Billings will speak on "Physical Reconstruction of the Disabled," and Capt. A. E. Bott, C. A. M. C., on "The Mentality of Convalescence."

Nurses Continue Suit.—Although the strike of the nurses of the Oak Park Hospital was called off, two of the striking nurses are said to have filed a petition in the circuit court to have the hospital prosecuted for alleged violations of the law, and to force the hospital authorities to obey the ten hour law.

Personal.—Mark Greer, Lieut., M. C., U. S. Army, Vandalia, now on duty with the British Expeditionary Forces, has been commissioned Captain, M. C., and returned to the United States, and expects to be separated from the service in a few days.——William D. Chapman, Capt., M. C., U. S. Army, Silvis, has returned from military service, and resumed practice.——Dr. William H. Conser, Lieut., M. C., U. S. Army, Cambridge, who has been in France for eight months, has been honorably discharged.

Illegal Practitioner Fined.—April 3, the Department of Registration and Education of the State of Illinois secured the conviction in the courts of Madison County of Reverend Davis, a colored man who was practicing medicine without a license. He was fined $115 and sent to jail to work this out. The business cards used by this man announced that he was "the world's greatest wonder; born with a full set of teeth; talked in ten days after birth; revealed to his father, who is now 107 years of age, that he would live to be 112 years old; revealing spiritualist and stomach guarder."

Chicago

Hospital to be Dedicated.—It is announced that the remodeled Mount Sinai Hospital, 1519 South California Avenue, will be formally dedicated, May 4.

Chicago Drugs Found in San Francisco.—Federal authorities, April 12, arrested a man in San Francisco in whose luggage, which had been checked through from Chicago, were discovered habit-forming drugs valued at $10,000.

Industrial Surgery Meeting.—April 15, the Illinois Manufacturers' Association held a dinner and discussion on industrial surgery in connection with the Chicago Safety Council. Dr. Loyal A. Shoudy, Bethlehem, Pa., chief surgeon of the South Bethlehem Steel Corporation, spoke on "Fifteen Functions of an Industrial Surgeon," and Paul B. Magnuson, medical director of the Industrial Commission of Illinois, on "The Present Deficiency of Surgical Treatment and After-Treatment of Accidents." Dr. Leroy P. Kuhn, chief surgeon of the Illinois Manufacturers' Casualty Association, presided.

Tuberculosis Society Meeting.—At the meeting of the Robert Koch Society for the Study of Tuberculosis, at the city club, April 22, at 8 p. m., the subjects for discussion are "The Relation of Dust to the Spread of Tuberculosis," by Dr. Henry C. Sweany, and "The Prevention of Relapses in Cases of Arrested Tuberculosis in Soldiers and Sailors," by Dr. S. Adolphus Knopf of New York, with demonstration of massotherapy, hydrotherapy and respiratory therapy on a subject.

Personal.—Dr. Orville W. McMichael, formerly director of the Edward Sanatorium, Naperville, and consulting director of the Rockford Municipal Sanitarium, and more recently medical director of the Winyah Sanatorium, Asheville, N. C., has severed his connection with the latter institution, and resumed private practice in Chicago.——Lewis Wine Bremerman, Lieut.-Col., M. C., U. S. Army, in command of the 310th Sanitary Train, American Expeditionary Force, arrived in New York from France, April 10.——Payson L. Nusbaum, Major, M. C., U. S. Army, in command of Base Hospital Unit No. 12, American Expeditionary Forces, arrived in New York, April 2.——Kellogg Speed, Major, M. C., U. S. Army, returned, April 11, after a long term of service on the western front.

MARYLAND

Personal.—John M. T. Finney, Brig.-Gen., U. S. Army, Dr. Hugh H. Young, formerly Colonel, U. S. Army, and Dr. William S. Thayer, formerly Brig.-Gen., U. S. Army, Baltimore, were given the Distinguished Service Medal by Secretary of War Newton D. Baker, for exceptionally meritorious and distinguished service.——Dr. Clement A. Penrose, who has been ill at his residence in Baltimore, is slowly convalescing. While in France, Dr. Penrose was seriously ill with septic poisoning, and his present condition is the result of the poisoning.

Clinic for Women.—In line with the lectures on motherhood, which are being given in Baltimore by Dr. J. Whitridge Williams, Baltimore, in connection with the School of Hygiene and Public Health, a clinic for women will be organized at the Johns Hopkins Hospital sometime within the year. The clinic now in use there has about seventy beds; the new clinic will have 150. This has been made possible by an anonymous gift from a woman of $400,000 to be used for the building. The teaching staff and equipment will be supplied by the General Education Board. The second of the motherhood lectures given by Dr. Williams and sponsored by the Women's Section of the Maryland Council of Defense was held, April 10, at McCoy Hall, and dealt with "Reproduction and Heredity." The need not only for these lectures but also for the women's clinic is demonstrated by the report of the Federal Children's Bureau on maternal mortality, in which it is shown that annually about 15,000 women die in childbirth in this country whose deaths might have been prevented by proper care.

MASSACHUSETTS

School for Physicians to Open.—The opening of the "School for Doctors," under the direction of Drs. Richard C. and Hugh Cabot is announced at the Massachusetts General Hospital by Dr. Joseph B. Howland. Clinical and pathological conferences will be held every Tuesday from 12 to 1.

Putnam Memorial Professorship.—An effort is being made to raise $50,000, of which more than half has already been pledged, for the endowment of a professorship of diseases of the nervous system, in memory of Dr. James Jackson Putnam, Boston, who inaugurated the neurologic clinic at the Massachusetts General Hospital in 1872, and who devoted more than forty years of service to its interests and to teaching in Harvard University Medical School. In 1893, Dr. Putnam was appointed the first professor of diseases of the nervous system, but the chair was then, and is still, without endowment.

Personal.—Dr. Eoline B. C. DuBois, Springfield, has returned after a year of service, and resumed practice.——Dr. Samuel W. Ellsworth, after service in France, has been reinstated in his position in the roentgen-ray service at the Boston City Hospital, and Dr. Patrick F. Butler has been reassigned as assistant physician in this department.——Frederic A. Washburn, Lieut.-Col., M. C., U. S. Army, organizer of Massachusetts General Hospital Unit, which operated at Base Hospital No. 6, Bordeaux, has returned from France.——Dr. Horace D. Arnold, Boston, has resigned as director of the Graduate School of Medicine of Harvard University.

MINNESOTA

Y. W. C. A. Given Mayo Home.—Dr. and Mrs. Charles H. Mayo have presented their town house in Rochester to the Young Women's Christian Association of the city.

Clinical Association Organized.—At a meeting of thirty-seven physicians and interns of the medical staff of the Minneapolis City Hospital, March 28, a constitution and by-laws were adopted. At the next meeting, April 25, a scientific program will be presented.

Public Health Nurses Now Available.—The bill authorizing city and village councils, boards of county commissioners, and town boards to employ public health nurses has passed both houses of the legislature. Under directions of this bill, public health nurses are now legally available throughout the state.

Personal.—Clarence C. Burlingame, Major, M. C., U. S. Army, Fergus Falls, formerly on the staff of the state hospital, has been decorated by the Polish government.——Charles R. Ball, Lieut., M. C., U. S. Army, St. Paul, who has been on duty at American Red Cross Hospital No. 1, Paris, since September, 1918, has returned home.——Dr. Gustav A. Renz, assistant chief city health officer of St. Paul, is reported to be seriously ill with malignant disease of the mouth and throat.

MISSOURI

State Association Meeting.—The annual meeting of the Missouri State Medical Association will be held at Excelsior Springs, May 26 to 28, with headquarters at the Elms Hotel.

Fordyce in St. Louis.—At a meeting of the St. Louis Medical Society, April 12, a paper was read by Dr. John A. Fordyce, New York, professor of dermatology and syphilology in the College of Physicians and Surgeons in the City of New York, on "The Results Obtained in the Treatment of Neurosyphilis by Intraspinal Injections."

Personal.—Arthur Gundlach, Capt., M. C., U. S. Army, St. Louis, who was secretary of the St. Louis Medical Society when he accepted a commission in the Medical Corps of the Army, has been honorably discharged and has returned.——Dr. Albert F. Koetter, who has been acting as secretary in Dr. Gundlach's absence, resigned on Dr. Gundlach's return and the council thereupon reelected Dr. Gundlach secretary.——Dr. Dora Green Wilson, Kansas City, sustained a fracture of the left clavicle, March 17, in a collision between her motorcar and a street car.

NEW JERSEY

Tuberculosis Clinic Opens.—The antituberculosis clinic at 82½ Lexington Avenue, Passaic, was opened to the public, April 8. The rooms are to be open every Tuesday and Friday from 3 to 5 p. m., and are in charge of Dr. Joseph F. A. Rubacky.

Marriage Examination Law.—Under bills passed in the House, April 8, a physician's certificate becomes a prerequisite to marriage in New Jersey. The purpose of the bill is to prevent the marriage of persons afflicted with contagious or infectious social diseases. The bill provides that the fee of a physician for making the necessary examination before the issuance of a certificate shall not exceed $2.50, and county physicians will be required to make such examinations gratuitously to indigent applicants. The bill was indorsed by the officials of the U. S. Public Health Service and the state department of health, and was approved by the Surgeon-Generals of the Army and Navy.

NEW MEXICO

Personal.—Dr. James F. Chalmers, East Las Vegas, has resumed charge of the Santa Fe Railway System Hospital at Fort Madison, succeeding Dr. Bishop, who has been transferred to Topeka, Kan.

Governor's Signature Alone Required.—The public health bill has become practically a reality, lacking only the governor's approval. The house bill was passed by the senate, March 13, with a large number of amendments in which the house concurred, March 14.

Medical B[illegible].—The governor, March 22, appointed th[illegible] of medical examiners for the state: Drs. Miguel F. Desmarais, Las Vegas; Charles B. Kohlhousen, Raton; Creighton H. Ferguson, Tucumcari; John A. Reidy, Albuquerque; Robert E. McBride, Las Cruces; Carey B. Elliott, Dawson, and Jose M. Diaz, Santa Fe.

NEW YORK

Medical Club Meeting.—At the annual meeting of the Utica Medical Club, March 20, Dr. Hyzer W. Jones was elected president, and Dr. Arthur M. Johnston, secretary-treasurer.

Clinic Opens.—A free medical clinic under the auspices of the Geneva Board of Health was opened, March 27, in the board of health rooms in the city hall under the charge of Dr. F. Lansing Stebbins. The clinic will be open every Thursday afternoon until further notice, and all children in the city under 16 years of age are requested to visit the clinic and be examined.

Public Health Nurse Preparation.—Under the auspices of the New York State Department of Health, with the cooperation of the Rochester Health Bureau, Rochester Tuberculosis Association and the Monroe County Red Cross branches, a course of study in public health nurse preparation is being given this month at the University of Rochester, under the direction of Dr. Bertis R. Wakeman, Hornell, sanitary supervisor of the New York State Department of Health.

Personal.—Dr. Paul G. Taddikin, superintendent of the Buffalo State Hospital, has resigned to become superintendent of the Ogdensburg State Hospital.——Dr. Fowler A. Watters, health officer and city physician of Lockport, for twelve years past, has resigned, and Dr. Thomas E. Spalding, Lockport, has been appointed to fill the unexpired term.——Michael J. Thornton, Major, M. C., U. S. Army, Albany, has been promoted to Lieutenant-Colonel, M. C., U. S. Army, and has returned from abroad.——Dr. Milton P. Messinger, Oakfield, who has been on duty with the American Red Cross in France since October, has returned home.——Milton Chapman, Capt., M. C., U. S. Army, Rochester, who was on duty with the 42d Field Artillery on the western front, has returned and will resume practice.

New York City

Surgical Society Elects.—At its annual meeting, April 9, the New York Surgical Society elected Dr. William A. Downes, president; Dr. John A. Hartwell, vice president, and Dr. Ransom S. Hooker, secretary.

New Hospital for Drug Addicts.—A new hospital, recently established by the health department on North Brother Island, will be devoted to the treatment of drug addicts. The hospital has a capacity of 200 beds, and will receive patients committed by the courts as well as self-committed persons who desire to be cured of the drug habit.

Personal.—Robert Emery Brennan, P. A. Surg., U. S. Navy, has been given an honorable discharge.——Dr. Joseph A. Blake, formerly surgeon of the American Hospital at Neuilly, near Paris, sails for New York, April 19.——Dr. Irving F. Wallace, in charge of the maternity school at Bellevue Hospital, has resigned and will resume practice.——Dr. William L. Wolfson, Brooklyn, announces his return from France and resumption of practice, April 13.——Dr. Laura M. Riegelman, Brooklyn, has been placed in charge of the bureau of child hygiene for the department of health of Brooklyn, replacing Dr. John H. Plath.——Dr. David S. Flynn has been appointed director of the state employment bureau.

NORTH CAROLINA

Student Nurses Strike.—After sending in a petition to the trustees for better food, higher wages and more privileges, twenty-two student nurses of the Rex Hospital, Raleigh, quit the institution on strike.

Memorial to Nurses.—Patriotic citizens of Raleigh have arranged for a memorial to the volunteer nurses who cared for the sick during the recent influenza pandemic. For this memorial it is proposed that two public drinking fountains be erected.

Full-Time Health Officer.—Vance County has recently made arrangements to have a full-time health officer, arranging with the state board of health and the International Sanitary Commission for an intensive health campaign. There will be an office assistant to the health officer, and a nurse for rural sanitation and infant hygiene work. Forsythe, Davidson, Lenoir, Pitt, Robeson, Rowan, Nash, Northampton and Wilson counties are each now operating similar intensive health plants. The average typhoid fever deaths in the nine counties from 1914 to 1917 was 120 per year, with a death rate of 35.2. During 1918 there were only twenty-four deaths from typhoid in the nine counties, the rate being 7.8. During the war the whole-time health work was suspended in Vance County.

PENNSYLVANIA

Officers Return from Abroad.—John W. Burkett, Lieut., M. C., U. S. Army, Moon Run, and John F. Golden and Robert T. Hood, Lieuts., M. C., U. S. Army, Pittsburgh, have returned from abroad.

Three Years' Accidents Cost $30,000,000.—Nearly $30,000,000 have been awarded in three years under the provisions of the workmen's compensation act for the injured and families of those killed at their work. In three years, 6,668,348 accidents show that labor casualties furnish a startling comparison with those on the battlefield. The fatalities for the period reached 9,143.

To Improve Sanatoriums.—Extensive improvements are planned for the state's three tuberculosis sanatoriums at Mont Alto, Crescent and Hamburg, carrying on to a still greater efficiency the work done by the late Dr. Dixon. Plans have been drawn by the present commissioners of the health department for alterations and improvements at the three institutions which will cost approximately $300,000 for Mont Alto and $100,000 each for Crescent and Hamburg.

Physicians and Industries Get Together.—The acting commissioner of labor and industries has offered the services of the state to enable industries and physicians and surgeons to get together, because of the numerous requests for information regarding opportunities for industrial service in Pennsylvania which are being received from medical officers discharged from the military service. This feature of the state work is in the hands of Dr. Francis D. Patterson, Harrisburg, chief of the Bureau of Hygiene.

Philadelphia

Reception for Surgeon-General.—A reception was held by the Medical Club of Philadelphia for Major-Gen. Merritte W. Ireland, M. C., U. S. A., at the Bellevue-Stratford, April 18. Major William Keen, M.D., LL.D., was elected to honorary membership in the club.

Schools Insanitary.—According to the annual summary of investigation of schools submitted by Dr. Bernard Kohn, acting director of medical inspection of public schools, 101 schools are enumerated, as overcrowded, 75 lack sufficient illumination, 90 have inadequate yard space, 64 are deficient in exits and fire escapes, and 26 are insufficiently equipped with drinking water accommodations.

Gift to a Hospital.—A new maternity building to take the present site of the Smith Memorial Hospital of the Lankenau Institution and to cost about $125,000 has been donated by Charles H. Smith, a brother to the president of the Lankenau Hospital. The proposed new building will have a greater capacity than the one now in use, and while there will be several private rooms the donor will permit the construction of the building only with the definite assurance that it will be used entirely for poor women.

Personal.—Dr. Alexander C. Abbott, professor of hygiene at the University of Pennsylvania, and in charge of sanitary supervision for the Second Army, American Expeditionary Forces, has been promoted to colonel.——Walter A. Wood, Capt., M. C., U. S. Army, now in charge of the evacuation hospital at Coblenz, Germany, has been promoted to major.——Philip Atlee Sheaff, Major, M. C., U. S. Army, who has been with U. S. General Hospital No. 36, Detroit, as chief of the medical service, has been discharged and has returned to his practice in this city.——Lieut.-Col. Thomas H. Johnson, on duty with Base Hospital No. 29, University of Pennsylvania Unit, has been awarded the médaille d'honneur des épidémies by the French government.——Joshua E. Sweet, Major, M. C., U. S. Army, on duty with Base Hospital No. 10, has been promoted to lieutenant-colonel.——J. Chalmers DaCosta, Lieut.-Com., U. S. Navy, sailed on the *George Washington,* April 11, for France.

VIRGINIA

Personal.—Dr. William S. Keister, Roanoke, has been in conference with the state health officer of Alabama and is considering the acceptance of the position of field director of sanitation. This will include the charge of the five units cooperating with the International Health Board. Dr. Keister recently returned after ten months' service with the American Expeditionary Forces.

Must Report Vital Statistics.—The state board of health has served notice that all physicians and undertakers who fail to report vital statistics or fail to secure burial permits will be prosecuted. Dr. Oscar E. Bevins, Dungannon, is said to have pleaded guilty recently to the charge of failure to report three births, and was fined $5 on each offense. An undertaker of Broadway was fined on each of three charges of failure to report deaths and failure to secure burial permits.

CANADA

University Principal Resigns.—Principal Sir William Peterson of McGill University, Montreal, has resigned, and Sir Auckland C. Geddes, formerly professor of anatomy, has been appointed to succeed him.

Smallpox in Quebec.—Dr. Elzéar Pelletier, Montreal, of the provincial board of health of Quebec, reports an unusual number of cases of smallpox throughout that province. Fifty localities are affected, and there are more than 400 cases in the province. There are 1,200 municipalities in Quebec province, and 716 have adopted a resolution to establish compulsory vaccination. Some parishes in the neighborhood of Montreal are affected, and the provincial board of health has been made a center to direct the campaign against the incipient epidemic.

LATIN AMERICA

Workmen's Compensation.—Recently enacted legislation, officially promulgated by the vice president of Brazil by decree of Jan. 15, 1919, provides compensation for workmen killed or injured in the performance of labor or contracting disease in the performance of such labor, the laborer, his family or his heirs being entitled to receive such compensation from the employer.

GENERAL

Gorgas en Route to Ecuador.—Major-General William C. Gorgas, former Surgeon-General of the Army, and a party of sanitary experts arrived in Panama, April 3, and left April 7, for Guayaquil, Ecuador, to investigate sanitary conditions in that place and country.

Encephalitis.—This disease has appeared at the following places, among others, since April 1: Wallace, N. C.; Des Moines and Emmettsburg, Iowa; Chicago and Aurora, Ill.; St. Joe, Mich.; La Crosse, Wis.; Fargo, N. D.; Kansas City, Mo.; New Orleans, Alexandria and Lake Charles, La., and Birmingham, Ala.

Transportation of Sick and Wounded.—During March, 20,080 patients were transferred by the evacuation officer at Hoboken, N. J., to hospitals in various parts of the country, and these transfers were made from debarkation hospitals without a single accident. March 29, a hospital train left Hoboken with 2,011 patients, the largest record for transporting sick and wounded for a single day.

Personal.—Miss Lucy Minnegero, Fairfax, Va., chief nurse of the American Red Cross Unit, which was sent to Kief, Russia, in 1915, and later was superintendent of nurses at Columbia Hospital, Washington, D. C., and who since 1917, has been in charge of the preparation of the Red Cross nurses for assignment overseas, has been appointed superintendent of the U. S. Public Health Service Nurse Corps.

For a Campaign Against the Fly.—In the interest of a fly-killing and prevention campaign, the agricultural extension division of the International Harvester Company is distributing a pamphlet giving methods and materials for fighting the fly, and offers to lend charts and lantern slides for the use of persons or organizations in communities where fly-killing campaigns are to be conducted. The fly-breeding season is here, and efforts expended now will have the best results.

Funds Urged for Venereal Disease Control.—In a telegram sent out to state boards of health by the Surgeon-General of the U. S. Public Health Service, April 1, it was announced that the following sixteen states had already made appropriation for venereal disease control: Texas, Alabama, West Virginia, Maine, Washington, North Dakota, South Carolina, Delaware, New York, Utah, Wyoming, Oklahoma, Arizona, Oregon, Wisconsin and Iowa, and it was urged that the remaining states take immediate action to secure the federal aid available for this work.

Bequests and Donations.—The following bequests and donations have recently been announced:

Harvard Medical School, an anonymous donation of $50,000 for the establishment of the James C. Melvin fund for tropical medicine, the income to be used for research in medicine.

Hartley Laboratory, Columbia University, a gift of $2,000 by Mrs. Helen Hartley Jenkins.

For additions to the medical school buildings of the College of Physicians and Surgeons in the City of New York, a donation of $1,000 from Mrs. V. Everett Macy.

The German Hospital and Dispensary, Mount Sinai Hospital, Home for Aged and Infirm Hebrews, Montefiore Home for Chronic Diseases and Charity Organization Society of New York City, each $2,500; National Jewish Hospital, Denver, $2,500; Lebanon Hospital, St. Mark's Hospital for Deformities and Joint Diseases, and Mount Sinai Hospital Training School for Nurses, New York, each $1,000, and the United Hebrew Charities, $5,000, by the will of Emil Schweinburg.

FOREIGN

Personal.—Dr. T. A. Henry, superintendent of the laboratories of the Imperial Institute, London, has been appointed director of the Wellcome chemical laboratories.——Dr. F. L. Pyman has been appointed professor of technological chemistry in the Manchester Municipal College of Technology and the University of Manchester.——Dr. Janet Mary Campbell, London, has been appointed a medical officer of the British Local Medical Board with special charge of the work in respect to maternity and child hygiene.——Dr. George Barger, research chemist to the Medical Research Committee of the National Health Insurance, has been appointed to the chair of chemistry in connection with medicine at the University of Edinburgh.

Deaths in the Profession Abroad.—The *Nederlandsch Tijdschrift* reports the death of Dr. **F. Schauta**, professor of gynecology and obstetrics at the University of Vienna since 1891, aged 70. The list of his works and manuals on these specialties is a long one, but his name is best known, perhaps, by his advocacy of the vaginal route for operations on the uterus.——Dr. **E. W. Nordenson**, a leading Swedish ophthalmologist, prominent in public health work and in the work of the Swedish Medical Association. He was especially watchful over the character of the advertisements accepted for the publications of the association, including its monthly, *Hygiea*. His principal monographs were on detachment of the retina and on nervous diseases affecting vision. He had had a private eye clinic at Stockholm for nearly thirty years.——Dr. **F. Carriazo** of Seville, Spain, a specialist in radiology since 1897. In 1915 he had to have a finger amputated on account of a roentgen cancer and recently succumbed to the effects of its generalization.

CORRECTION

Child Welfare Congress to Be Held in Montevideo in May, 1919.—In our issue of February 15, Medical News section, we published an item taken from an exchange to the effect that the second Congreso Americano del Niño (Child Welfare Congress) which was to have been held at Montevideo, Uruguay, last December, had been postponed until May, 1920. In a cablegram just received from Dr. Luis Morquio of the above mentioned city, he states that the congress will be held in May of this year.

BUENOS AIRES LETTER

Buenos Aires, March 13, 1919

The Spanish Edition of The Journal

The edition in Spanish of The Journal of the American Medical Association is meeting with a most favorable welcome.

Entrance Examinations

The evident lowering of the standards of the secondary studies in recent years has impelled the Facultad de Medicina to insist on an entrance examination in physics, chemistry and natural sciences, in addition to the diploma of graduation which they have hitherto accepted as sufficient without necessity for further examination. The recent graduates of the national *colegios* have petitioned for the abrogation of these entrance examinations, insisting that the diploma of graduation should entitle them to admittance to the medical school. The latter, however, has legally the right to exact such examinations as it deems proper. The entrance examination was demanded by both professors and alumni on different occasions. One of the reasons which led to its adoption was the excessive number of matriculates in the first years of the medical course. Some of the courses had 800 inscribed which large number rendered practical instruction for all impossible. As 75 per cent. of the matriculates failed to conclude the course, it was deemed best to make a selection from the beginning and avoid the drawbacks of carrying a large number of students who are wasting their time in studies they will be unable to complete.

Opening of the Medical School Year

The school year will be officially inaugurated, March 20, in the Facultad de Medicina with a solemn session, the dean, Dr. J. Mendez, presiding. The classic date for opening the school has always hitherto been March 15, and the opening occurred without any ceremonies.

Epidemics in Northern Argentina

The epidemic of plague which has been prevailing in certain districts of the Jujuy and Salta provinces has declined. The death rate has been considerable as very acute cases and the septicemic forms were frequent. New cases of exanthematous typhus have appeared in the province of Jujuy, especially at Tilcara. The cases are isolated, which is not surprising as the zone affected is mountainous and the population scanty.

There has been a recrudescence of malaria. The Dapartamento Nacional de Higiene has organized anew the sections for defense against malaria. These sections had been reduced or suppressed entirely in the last few years. Complaints are being received as to an insufficient supply of quinin.

Reorganization of the National Public Health Service

In February the reorganization of the Bacteriologic Institute of the Departamento Nacional de Higiene was officially approved. The technical personnel were declared in commission about a year ago. Most of the personnel have been confirmed in their appointments but the new assistants were appointed directly, without any competitive examination such as has always been the rule hitherto.

Funds for the Public Hospitals and Charity Work

A subscription was recently collected to increase the funds available for the Asistencia Publica of the capital; the amount collected has not yet been made public.

At the time of the carnival festivities, the Asistencia Publica also was authorized to organize a festival in the Avenida de Mayo, that is, in the principal avenue of the city; the sums realized therefrom to be devoted to the city hospitals. The festival was a success, but owing to inefficient management of the entrance payments, the sum realized amounted only to $8,000.

LONDON LETTER

London, March 27, 1919.

The Influenza Epidemic

The third wave of the influenza epidemic has now ended. The deaths from the disease recorded for the *ninety-six* great towns of England and Wales last week numbered 3,218, compared with 3,889 the previous week. In London the deaths numbered 597, as against 808. The mysterious periodicity which the disease seems to have established for itself has been maintained. This periodicity is roughly twelve weeks. The first wave began in July and died down about the end of August—a two months' course. Twelve weeks after the beginning of the first wave—at the beginning of October—the second wave began to flow. This wave was spent by the middle of December. Again twelve weeks after the beginning of the second wave, that is, in January, the third wave appeared. It had begun to spend itself in the first days of March. If this periodicity is continued we may look for a fourth wave, beginning some time in April and ending about the first week in June.

Medical Graduate Course in London

Further particulars of the medical graduate course in London (The Journal, March 8, p. 742) may be given. Arrangements have been made with all the medical hospital schools, two other general hospitals, and the following special hospitals: Cancer, Chelsea Hospital for Women, Hospital for Children, National Hospital for Diseases of the Heart, National Hospital for the Paralysed and Epileptic, Queen's Hospital for Children, Hackney Road, St. Mark's Hospital for Diseases of the Rectum, St. Peter's Hospital for Urinary Diseases. Arrangements are being made for a definite course of daily lectures and demonstrations on special subjects at the Royal Society of Medicine. Graduate instruction has received a great stimulus from the large number of physicians in the armies of the dominions and the United States who are taking the opportunity while in Europe of profiting by their sojourn here. In the case of the dominion armies, special leave for three months for this purpose is granted to medical officers. For many years, attempts have been made to put graduate teaching in London on a satisfactory basis but, as stated in previous letters, without success. A new spirit has been awakened since the war, and it is recognized that the impossibility of resorting to the German schools for some years to come furnishes a great opportunity. A public meeting is about to be held in London under the chairmanship of Sir William Osler when a scheme, which has received the approval of the London medical schools, will be considered. It is proposed that the instruction shall comprise general and special courses, and that after attending one of the latter a graduate may apply to the teacher responsible for the courses for permission to do research work under him or to act as his clinical assistant. Thus after attending a course on children's diseases of orthopedics he could, if regarded as sufficiently qualified, stay on at the hospital as clinical assistant, or do research under the physician for children's diseases or the orthopedic surgeon. Those who have given graduate instruction in the London graduate schools and special hospitals in the past will continue to do so in cooperation with the other teaching institutions working with the association, which include all the undergraduate medical schools in London. The medical schools of the United Kingdom will be invited to cooperate with the London association in providing periodic courses to run concurrently, especially at times, such as the summer months, when those seeking to attend courses will probably exceed the number that can be dealt with adequately in London. The recently formed British Association of Radiology and Physiotherapy has agreed to cooperate.

Birth Control

In view of the fact, mentioned in my last letter, that in the last quarter there were in England and Wales 79,443 more deaths than births, special interest attaches to the meeting of the National Birth Rate Commission (instituted by the National Council of Public Morals). Dr. C. K. Millard, health officer for Leicester, dealing with the declining birth rate, said that the question of the birth rate was intimately bound up with that of birth control. It was unfortunate that scientific study of the subject had been hitherto neglected. Owing to the supposed moral stigma many had tabued it, and it was only quite recently that unbiased discussion had become possible. The subject was of special interest and importance at the present day, through conditions arising out of the war. In many parts of Europe the social conditions of the people, with starvation staring them in the face, without proper clothing or shelter, with civilization itself breaking down, were deplorable in the extreme. It appeared to him eminently desirable that rigid birth control should be practiced in those countries, and probably in others also, if acute maternal suffering and terrible infant mortality were to be avoided. The best thing for the people of those countries to do was temporarily to stop having children, so far as it could be avoided, until happier and more prosperous times arrived. It seemed to have been taken for granted in most countries that rapid increase of population was needed in the national interest, and that a stationary population would be disastrous. No doubt this sentiment was really based on militarist considerations, and in the past, when such considerations were vital, it might have been wise to encourage it. But now, with the international situation fundamentally altered, and with the League of Nations (whose special function it would be to safeguard the nations with small populations), it was time to reconsider our attitude. International competition in birth rates was to be avoided, just as was competition in armaments. There were certain countries which were already "saturated" as regards population, in the sense that any further increase would not tend to increase the happiness or prosperity of the inhabitants. Wherever that point had arrived, or was nearly at hand, he regarded birth control as the proper remedy, and as greatly preferable, in most cases, to emigration. The case of our own country was complicated by the fact that she was the mother country of an empire. Many people would agree that the population of the British Isles was large enough, but they wanted to see our great colonies filled up with an all British population. No doubt this was very patriotic, from the standpoint of conditions before the war; but from the point of view of the League of Nations we ought to regard our colonies as the natural outlet for the surplus population of all European countries. It was so necessary for the peace of Europe that such an outlet should exist that we need not be in any hurry to see those territories filled up. As to the question of practical methods, physicians had not given it sufficient attention to enable them to speak very authoritatively. Certain physicians, with obviously a strong bias on moral grounds, had condemned all methods as highly injurious, and the bishops in the special report on this subject presented to the Pan-Anglican Conference in 1908, had seized on isolated medical opinion of this kind and used it as though it were the considered verdict of the medical profession. To ascertain what was the real opinion of the profession of the present day, Dr. Millard had recently issued a questionnaire to medical practitioners, and from some eighty replies received he was quite satisfied that the great majority of the profession did not regard birth control as necessarily injurious.

The Venereal Danger to the Troops of the Occupied Area

Attention has been called in the press to the venereal danger to which the British troops, largely young soldiers, are exposed in the occupied portion of Germany. The Germans took elaborate precautions for the health of their troops in town areas, and on the whole were successful. They isolated and kept under surveillance all women suffering from contagious diseases; but when it became known that the Allied troops were to occupy the town, these women were released. A German official interrogated on the subject said that they had "escaped." Many of their towns, among which Cologne has a certain notoriety, have proved hotbeds of disease, and there is some reason to believe that pains have been taken in a manner not infrequently adopted by conquered people in the East to endanger our troops. It is reported that since the occupation, venereal disease has become much more prevalent among them. The government has been asked to take the requisite precautions.

PARIS LETTER

Paris, March 13, 1919.

An American Hospital to Be Established in France

Colonel House has informed M. André Tardieu, general commissioner of Franco-American War Welfare, of the project to create in Paris a hospital to be built by Americans in commemoration of soldiers of the United States who died in France during the war. This matter was submitted to Colonel House by Dr. Kenneth Taylor who, during the four years of the war, has devoted himself particularly to the question of hospitalization in France, and is now director of an American Red Cross Hospital, No. 2 rue de Puccini, Paris. This institution would care for French and Allied patients, and would also strengthen the union between French and American medical men, by giving courses teaching American medical students French methods, and demonstrating American methods in the clinics which would be open to French students. This hospital would be a center of French and American documentation and would serve likewise as a training school for French and American nurses.

Compulsory Notification of Tuberculosis

This question was discussed recently by the Académie de médecine. Dr. F. Bezançon, professor of bacteriology in the Paris medical faculty, presented the report of the Commission permanente de la tuberculose. The conclusions on which the discussion hinged were as follows: "The Commission permanente de la tuberculose is of opinion that compulsory notification is one of the fundamentals in the campaign against tuberculosis, but that it is merely one phase of the work; the campaign against alcoholism and against insanitary dwellings should likewise command the attention of legislators. The attending physician should register the case, and by making the notification to the health officer, he does not violate professional secrecy. This does not preclude notification by the party most interested or by the head of the family. Notification should be limited to open cases of pulmonary tuberculosis, and it should not be enforced until the prophylactic measures and necessary assistance can be realized. The committee seizes this occasion to request that the Académie vote a resolution asking for the creation of an Institut national d'hygiène for the purpose of promoting hygiene and training competent hygienists."

This subject was also discussed by the Société médicale des hôpitaux de Paris. Dr. Emile Sergent would restrict notification at present to the open cases of pulmonary tuberculosis, cases in which the diagnosis is confirmed by demonstrating the tubercle bacillus in the sputum, such bacteriologic examination to be made in a reliable laboratory and to be accepted only when two successive examinations have been positive.

Dr. Dufour would register not only the open cases of pulmonary tuberculosis, but all cases of suppurating tuberculosis, of bone, for example, which may spread contagion.

He is strongly opposed to requiring bacteriologic proof based on special laboratory examination, but would hold the attending physician responsible.

Dr. Guinon believes that to demand the finding of the tubercle bacillus will leave unregistered many cases of tuberculosis.

Dr. H. Méry did not agree with these statements at all. They would require the notification even of cases of tracheobronchial gland tuberculosis. He would register all cases of contagious tuberculosis. This would exclude from the schools all teachers who are contagiously tuberculous.

Drs. Béclère, Brocq and Milian would provide the means for fighting the disease first, before insisting on compulsory notification.

Dr. Crouzon recalled that the war has compelled compulsory notification in the army with all its consequences of care for the sick, before and after their discharge from the army, and has resulted in creating an organization to fight the disease. The proposed law for compulsory notification of tuberculosis provides for an allowance to the families, and asks for an appropriation of 84 million francs to build hospitals, dispensaries, sanatoriums, disinfection centers, etc., and for the annual expense of maintenance. Crouzon believes, therefore, that under these conditions the principle of declaration cannot be rejected.

Dr. Armand-Delille, former chef de clinique in the Paris medical faculty, was of the opinion that such notification would be of great educational value to the public, but that it should be limited to cases of open pulmonary tuberculosis, because cases of open surgical tuberculosis do not spread bacilli much. Among 180,000 repatriates whom he examined at Evian he found about 1,400 cases of tuberculosis, in 30 per cent. of which tubercle bacilli were found. He concluded, therefore, that there are not more than 100,000 tuberculous individuals in France whose disease is contagious. He regards the present as a favorable time for notification because many buildings and measures installed by the Service de Santé militaire are now available for use in the campaign against tuberculosis.

Bezançon was formerly opposed to compulsory notification, but he is now an ardent advocate of this measure. This is because, along with the notification, many measures of great value are now being proposed. At the Conseil général de la Seine, the Office publique de lutte antituberculeuse is now engaged in the planning of dispensaries, hospitals and sanatoriums for the isolation and treatment of the tuberculous; in child welfare work; the establishment of school colonies; the campaign against slums, providing clean, sanitary homes, etc. What are the objections to this measure? It cannot prove objectionable to the family, because the notification will be made only to the sanitary inspector and he will order proper measures to be taken only if the family itself cannot provide the means to effect them. The attending physician should always state on the notification slip that the proper precautions have been taken, when this is so.

Dr. Carnot and Dr. Barbier, on the other hand, are opposed to this new measure believing that it will end only in failure.

American Red Cross Gives a Sanatorium

Miss E. Hoyt, secretary of the Commission de la Croix Rouge américaine in France, and Major A. H. Garvin, chef du Bureau de la tuberculose, have advised M. Autrand, prefect of the département de la Seine, that the American Red Cross, wishing to give evidence of its sympathy with the work of the Office publique d'hygiène sociale, and its great appreciation of the organization of the campaign against tuberculosis in the département de la Seine, will donate to the département for the use of this commission the sanatorium at Yerres (département de Seine-et-Oise).

M. Autrand expressed his heartfelt thanks for this generous act which again shows the valuable assistance which has been rendered to the sick, wounded and unfortunate French by the American Red Cross.

Personal

Dr. C. Achard, professor of pathology and general therapeutics in the Paris medical faculty, has been named professor of clinical medicine at his request. Dr. Cluzet, professor of medical physics in the Lyons medical faculty, has been named professor of physics, biology, radiology and physiotherapy.

Dr. Vincent, medical inspector and director of the laboratory of antityphoid vaccination and of serotherapy for the army, has been named inspector of the hygienic and epidemiologic services of the army, while still retaining his present activities.

Deaths

Joseph Ephraim Sawtell ⊕ Kansas City, Kan.; College of Physicians and Surgeons, Baltimore, 1886; aged 59; also a member of the Kansas Medical Society; professor of rhinology and otolaryngology in the University of Kansas, Lawrence; president of the Kansas State Medical Society in 1907-1908; for several terms president of the Wyandotte County Medical Society; formerly a member of the State Board of Medical Examination and Registration; a member of the staff of St. Margaret's, Bethany, Belle Memorial, Christian, and St. Joseph's hospitals; died at his home, April 4, from pneumonia.

Russell Cisney Parson ⊕ **Capt., M. C., U. S. Army,** Ambridge, Pa.; Jefferson Medical College, 1914; aged 27; who entered the service, Aug. 15, 1917; and after a special course in roentgenology, and tours of duty at Fort McHenry, Md., and Camp Gordon, Ga., was sent overseas with Evacuation Unit No. 13, and served as roentgenologist in the Toul Sector until December, when he was transferred to Camp Hospital No. 91 at Le Banle; died at that place, March 1, from epidemic lethargic encephalitis.

Lyman Henry Hills, Binghamton, N. Y.; New York University, New York City, 1863; aged 81; a member of the Medical Society of the State of New York; in 1870 president of the Otsego County Medical Society, and in 1899 president of the Binghamton Academy of Medicine; consulting physician to the Binghamton City Hospital; for several years a member of the local board of education, and for two terms coroner of Broome County; died at his home, March 21.

William Henry Comegys, Col., U. S. Army (retired), New York City; Miami Medical College, Cincinnati, 1876; aged 66; who entered the Army as an acting assistant surgeon in 1879 and served in the Geronimo campaign; and in 1881 was appointed major and paymaster, serving in that department until 1911, when he was retired at his own request after more than thirty years of service; died in the Presbyterian Hospital, New York City, March 31.

Francis Joseph Duffey ⊕ **Lieut.-Col., M. C., U. S. Army,** Brooklyn; Long Island College Hospital, Brooklyn, 1896; aged 44; a member of the New York Academy of Medicine; who recently returned from service with the American Expeditionary Forces in France; assistant visiting physician to the Post-Graduate Hospital and the Neurological Institute; died, March 31, from heart disease, while in attendance on a patient in Manhattan.

William Elton Guthrie ⊕ Bloomington, Ill.; Rush Medical College, 1881; aged 61; a specialist in surgery; local surgeon of the Chicago and Alton, and Lake Erie and Western railroads; once president of the Illinois State Medical Society; died in the Presbyterian Hospital, Chicago, April 6, a week after an ileostomy had been performed to relieve intestinal obstruction due to malignant disease.

James Harvey Wright ⊕ Pittsburgh; University of Buffalo, N. Y., 1878; aged 70; for several years city physician of Allegheny; a member of the staff of the Allegheny General Hospital since its organization; consulting physician to St. John's General Hospital; died in the West Penn Hospital, Pittsburgh, March 25, after a surgical operation.

Louis-Edouard Desjardins, Montreal, Que.; Ecole de médecine et de chirurgie, Montreal, 1864; Toronto School of Medicine, 1873; aged 81; who became professor of ophthalmology in his alma mater in 1882, and later was made professor emeritus; one of the pioneers of the French-Canadian medical institutions; died at his home, March 2.

Paul Herman Dernehl ⊕ Milwaukee; Johns Hopkins University, Baltimore, 1907; aged 40; a specialist in ophthalmology; a member of the American Academy of Ophthalmology and Oto-Laryngology, and a member of the staff of the Columbia, Children's and Mount Sinai hospitals, Milwaukee; died at his home, March 28, from diabetes.

John J. Hislop ⊕ **Capt., M. C., U. S. Army,** Miner's Mills, Pa.; Jefferson Medical College, 1892; aged 53; who entered the Army, Aug. 27, 1917, and after serving at Camp Wheeler, Macon, Ga., was discharged on account of physical disability, Dec. 10, 1918; died at his home, March 5, from cardiorenal disease.

Austin B. Allen ⊕ Maryville, Mo.; College of Physicians and Surgeons, Keokuk, Iowa, 1877; aged 69; a specialist in pediatrics; a member of the staff of Ensworth Hospital, St.

⊕ Indicates "Fellow" of the American Medical Association.

Joseph, Mo.; examining surgeon to the Omaha and St. Louis Railroad; died at his home, March 24, from arteriosclerosis.

William J. Andrews, Lakeside, Ohio; Medical College of Ohio, Cincinnati, 1865; aged 75; surgeon of U. S. Volunteers throughout the Civil War; a charter member of the Delaware County (Ind.) Medical Society; died in the Scarlet Oaks Sanitarium, Clifton, Cincinnati, March 26.

William Latimer Hall ⊕ **Lieut., M. C., U. S. Army**, Freedom, Okla.; Emory University, Atlanta, Ga., 1915; aged 29; who entered the United States service, June 1, 1918, and was sent to France, November 5; died in Marseilles, France, February 10, from bronchial pneumonia.

John R. Smith, Cleveland; Western Reserve University, Cleveland, 1879; aged 64; for several years professor of materia medica in his alma mater, and for three years house physician of Lakeside Hospital; died at his home, March 24, from cerebral hemorrhage.

Mary Elizabeth DeLong Pope Westcott, Lansing, Mich.; New England Female Medical College, Boston, 1865; aged 86; for several years a member of the faculty of her alma mater; died at the home of her daughter in Lansing, March 27, from bronchitis.

Edwin Jackson Kibbe ⊕ Aurora, N. Y.; College of Physicians and Surgeons in the City of New York, 1906; aged 39; until recently superintendent of the Queen Alexandra Sanatorium, London, Ont.; died in Aurora, about March 29.

Bradner Earl Gorham ⊕ **Lieut., M. C., U. S. Army**, Kent, Ohio; Grand Rapids (Mich.) Medical College, 1903; aged 37; who recently returned from military service; died in Lakeside Hospital, Cleveland, March 26, from pneumonia.

William Hilt, Pensauken, N. J.; Jefferson Medical College, 1884; aged 72; for many years a reporter on Philadelphia newspapers, and assistant city editor of the Philadelphia *Public Ledger;* died at his home, March 28.

Thomas Stratton Roberts, Long Beach, Calif.; Medical College of Ohio, Cincinnati, 1870; a member of the South Dakota State Medical Association; for many years a practitioner of Sioux Falls; died at his home, March 30.

William Beidler, Akron, Ohio; Medical University, Columbus, 1897; aged 51; a member of the Ohio State Medical Association; died at his home, March 28, from epidemic lethargic encephalitis following influenza.

David Clair Vosler ⊕ Ellwood City, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1894; aged 48; formerly captain, M. R. C., U. S. Army; died at his home, March 19, from organic heart disease.

John R. Absher, Foss, Okla.; University of Tennessee, Nashville, 1892; aged 62; was dragged by a cow he was leading, sustaining injuries as a result of which he died in the Clinton (Okla.) Hospital, March 27.

Eli Judson Peck, East Norwalk, Conn.; Bellevue Hospital Medical College, 1884; aged 70; for twenty-five years a practitioner of New York City; also a graduate in veterinary surgery; died at his home, April 3.

James Alexander Hutcheson, Lynbrook, N. Y.; Long Island College Hospital, 1874; aged 62; for several years health officer of Hempstead, L. I.; died at his home, March 30, from septic lymphadenitis.

George Edward Henderson ⊕ **Capt., M. C., U. S. Army**, Brooklyn; Long Island College Hospital, Brooklyn, 1907; aged 34; on duty with the 330th Field Artillery; died in France, February 12.

Cyrus Henry Pendleton, Hebron, Conn.; Western Reserve University, Cleveland, 1860; aged 88; a member of the Connecticut State Medical Society; died at his home, March 6, from heart disease.

Benjamin Fidler ⊕ New York City; Long Island College Hospital, Brooklyn, 1903; aged 47; radiotherapist and roentgenologist in the Mount Sinai Dispensary; died at his home, March 26.

Randall E. Poindexter, Benton, Ill.; Northwestern University Medical School, 1892; aged 56; local surgeon of the Illinois Central Railroad; died at his home, March 25, from heart disease.

George Willis Crosby ⊕ Sheboygan, Wis.; University of Michigan, Ann Arbor, 1884; aged 57; a specialist in genito-urinary diseases; died at his home, March 24, from cerebral hemorrhage.

Charles Milton Sawyer, National Soldiers' Home, Me.; Jefferson Medical College, 1872; aged 69; died in the National Soldiers' Home, February 11, from arteriosclerosis.

John Francis Abel ⊕ Chicago; Northwestern University Medical School, Chicago, 1879; aged 61; surgeon to the Southside Hospital; died at his home, April 3, from pleuropneumonia.

Charles Frederick Dole, Sharon, Mass.; Harvard University, Medical School, 1900; aged 43; a member of the Massachusetts Medical Society; died at his home, March 25, from paresis.

John Henry Bradsworth, Paterson, N. J.; New York Homeopathic medical College, New York City, 1881; aged 70; also a druggist; died at his home, March 20.

Simeon Otho Francis, White Bear Lake, Minn.; Minnesota Hospital College, Minneapolis, 1884; aged 58; died at his home, January 30, from cerebral hemorrhage.

Josiah Swinney, Bloomfield, Iowa; College of Physicians and Surgeons, Keokuk, Iowa, 1888; aged 61; once coroner of Davis County; died at his home, March 22.

Deborah K. Longshore, Topeka, Kan.; Woman's Medical College of Pennsylvania, Philadelphia, 1872; aged 77; died in Topeka, March 24; from heart disease.

Elton James Bassett, Taunton, Mass.; Harvard Medical School, 1869; aged 74; a member of the Massachusetts Medical Society; died at his home, March 16.

Noe Dumont, Little Falls, Minn.; Ecole de Médecine et de Chirurgie, Montreal, 1887; aged 56; health officer of Little Falls; died at his home, March 26.

Richard Henry Lawlor ⊕ Methuen, Mass.; Dartmouth Medical School, Hanover, N. H., 1898; aged 47; died at his home, February 12, from influenza.

Roy Oliver Thompson ⊕ Imperial, Calif.; College of Physicians and Surgeons, Los Angeles, 1914; aged 32; died in Imperial, March 25, from influenza.

Wade Hampton Sherrill, Philadelphia; Jefferson Medical College, 1916; aged 29; died at the home of his mother at Sherrill's Ford, N. C., March 25.

Bennie U. Spickard, Gem, Texas; University of Tennessee, Nashville, 1917; aged 40; died at his home, March 9, from pneumonia following influenza.

William Stark, Cincinnati; University of Berlin, Germany, 1858; aged 82; died at the home of his son in Cincinnati, March 9, from myocarditis.

Emanuel Sipes ⊕ Jacksonville, Ill.; Cincinnati College of Medicine and Surgery, 1887; aged 69; died at his home, March 1, from pneumonia.

Edward James O'Brien ⊕ Cheboygan, Mich.; Detroit Homeopathic College, 1910; aged 39; died in a hospital in Detroit, about March 26.

Lewis B. Griffith, Philadelphia; Hahnemann Medical College, Philadelphia, 1880; aged 61; died at his home, March 31, from heart disease.

Edward Stiles Allen ⊕ Providence, R. I.; Bellevue Hospital Medical College, 1876; aged 63; died at his home, March 29, from heart disease.

John Henry Pflueger, Holmen, Wis.; Starling Medical College, Columbus, Ohio, 1879; aged 65; died at his home, March 24, from heart disease.

Stanley F. Heskett, Chicago; College of Medicine (Physio-Medical), Chicago, 1887; aged 57; died at his home, March 29, from nephritis.

Marriages

William Ernest Kramer, Capt., M. C., U. S. Army, to Miss Kate Irene Peebles of Lawrenceville, Va., at Richmond, Va., March 26.

Leo Fleischer Stiendler, Capt., M. C., U. S. Army, Douglas, Ariz., to Miss Lucile Isabel Smith of San Antonio, Texas, March 8.

William Berry Marbury, Capt., M. C., U. S. Army, to Miss Violetta Carroll Mercer, both of Washington, D. C., April 2.

Burton James Lee, Lieut.-Col., M. C., U. S. Army, to Miss Louise Freeman, both of New York City, March 29.

Fritz Ernst Buchen, Wisdom, Mont., to Miss Frieda Louise Martini, at Butte, Mont., March 28.

Samuel Herman Lippitt to Dr. Eleänore Scholl Cushing, both of Milwaukee, April 7.

The Propaganda for Reform

GERMANY AND THE AMERICAN CHEMICAL INDUSTRY

Extracts from the Report of the Alien Property Custodian on the Chemical Industry

The average government report is notoriously dry and uninteresting. There are exceptions. The most recent of these exceptions is the chapter in the report of the Alien Property Custodian, A. Mitchell Palmer, recently made public which deals with "The Chemical Industry." This part of the report should be read by every man, physician and layman, who is interested in the larger industrial and scientific problems of the day, but especially should it be read by every physician.

At the outset, Mr. Palmer points out that the field of chemical industry was perhaps the most difficult of the many problems which his office was expected to solve. Chemical industry in the United States was saturated through and through by German influence, and in no branch of human endeavor was the myth of the German superman more firmly fixed in the public mind. The United States was flooded with chemists who were German either by origin, training or tradition. The chemical industry was certainly the most remunerative and probably the strongest of all Teutonic industries in the United States. The report briefly outlines the history of the German chemical industry. It shows how natural advantages and national characteristics combined to give Germany an advantage over the rest of the world.

GERMANY'S ADVANTAGES

"Labor was cheap, docile, and stable. On the other hand, the national habit of mind was peculiarly fitted for chemical research work, and particularly for the interminable tasks presented by such research, in the way of exhausting the immensely numerous possible combinations available within a particular field. From the first, scientific attainment, and particularly accomplishment in the field of research, appealed strongly to the public mind. Men of science, and particularly research workers, were more highly regarded than in other countries. This tendency was strongly fostered by the government, which, by conferring honors and titles, did everything possible to exalt the position of the successful scientist.

"As a consequence of these conditions, the universities were at an early date provided with the most elaborate and advanced equipment for research work, and attracted to themselves an extraordinary proportion of the ablest young men of the nation. They accordingly proceeded to turn out a constantly increasing number of highly trained technical men, whose services were available to the rising chemical industry. The number of these men was such that the inevitable competition between them for places made the average salaries exceedingly small. Highly skilled service was, therefore, available to the German chemical manufacturer at an extraordinarily low cost. In this respect he had a marked advantage over the manufacturers of any and every other country in the world."

These advantages did not give the German supremacy in the manufacture of what are known as "heavy chemicals," such as sulphuric acid, soda ash, etc. It did, however, give them an advantage, in fact it gave what was to all intents and purpose a world monopoly in two other great branches of chemical industry, which call for more difficult and complicated processes—that is, the practical application of organic chemistry to the manufacture of dye stuffs and medicinals. "The complexity of the manufacture of dye stuffs, as a business proposition," says the report, "is almost beyond belief." Nevertheless, over 900 distinct dyes were sold in logicciable quantities in the American market alone, before activities, each product requiring a separate and distinct process of manufacture, "one differing from the next in many cases as widely as if the products had been those of unrelated industries."

BY-PRODUCTS OF ECONOMIC AND POLITICAL VALUE

While all of these dye stuffs and many of these pharmaceuticals are derived from coal-tar, "they descend from this common ancestor by an enormous number of separate family lines." There are ten "crudes" which form the starting point of practically all the processes leading up to the production of dyes. From these ten there are more than 300 "intermediates" produced by more or less complex chemical reaction. While from the intermediates an almost infinite number of possible dye stuffs may be made.

The problem is, of course, largely restricted by the limitations of chemical laws. The most valuable of the modern dyes are derived from anthracene, obtained from the original coal-tar. The tar distiller, in producing anthracene, also produces or wastes enormously greater quantities of naphthalene, benzol and other crudes. The same principle obtains in subsequent steps of the complex processes of dye manufacture, whereby at each step large quantities of by-products are produced. The result is that the finished dye must either be sold at a tremendous price or else commercial uses must be found for the by-products. Some of these by-products have been found to have medicinal value, and have become established as pharmaceuticals.

"The most important feature, however, of this production of by-products is the relation which it bears to the explosive industry. All the most important explosives of the present day are either coal-tar products or the result of chemical processes requiring the use of coal-tar products. In a large dyestuff factory there is an unavoidable production of considerable quantities of substances which are directly available for conversion into explosives. A still more striking example is that of paramononitrotoluol. This is an intermediate necessarily made in quantities often beyond the needs of the dye makers. To the end of the last century many thousand tons of this substance had accumulated in the German dye works, which were making frantic efforts to find uses for it in dye making. About 1904 these efforts suddenly ceased. Trinitrotoluol (TNT) had been adopted as a military explosive, and every pound of the accumulation was directly available for easy conversion into this most formidable of high explosives."

GOVERNMENTAL SUBSIDIES

The report points out that three things were inevitable as the German dye industry developed. One was the necessity of immense resources in the way of capital and technic to carry out the business. The second, following as a result of the first, was that it was inevitable that large research laboratories must be maintained to work out the varied problems of disposing of by-products. The third was the government control of the dye industry because of its intimate relation with the explosive industry, and much was done by the German government "to insure the prosperity of the dye industry and its immediate convertibility to the production of munitions." This highly specialized industry, aided as it was by the government, led to overproduction, which in turn led to a determined effort to establish and maintain a large export trade.

KILLING AMERICAN INDUSTRIES

"The natural advantages of the German industry, as compared to the industry in other countries, prevented serious competition in Germany itself. The government's tariff and other policies enabled home prices to be kept up. It was then evidently to the advantage of any manufacturer to produce far more than he could sell in the home market, even if his export trade had to be carried on at a loss, when by so doing he could use a process so economical that his profits on home trade would be largely increased. Accordingly, German dyestuffs began to appear in every country at prices which domestic manufacturers could not meet. The inevitable result was that in country after country the domestic manufacture was destroyed or stifled in its cradle. As soon as this had been accomplished, it was no longer necessary for the German exporters to sell at or below cost. Prices were immediately raised and handsome profits realized. The tendency to this result was recognized by the German government from the first, and every facility was afforded to the growing export trade. It was fully realized by both the civil and military authorities that if a world monopoly in the dyestuff industry could be built up the military strength of Germany would be colossally enhanced, since it alone of all the great powers would then be in a position to secure immediate supplies of the vast quantities of munitions likely to be needed in modern war."

Specific instances of the German dumping policy are given in the report which shows, too, the way in which American manufacturers were forced to the wall. In addition to this, the Germans took advantage of the patent laws of the United States. "For example, Bayer alone accumulated in the neighborhood of 1,200 such patents which were placed in the hands of one of its subsidiary companies." In spite of the patents having been taken out, the German concerns made no effort, except in a few instances, to manufacture the products patented in the United States, showing that "these patents were obviously obtained and held in order to prevent the formation of an American dye industry and to make impossible importation from outer countries. The latter of these two purposes seems to have been the more important in the German mind. They seem to have had no fear that any American industry could be established on a competing basis."

GERMAN INDUSTRIAL FRIGHTFULNESS

The tactics thus described, while ruthless, were at least technically legal, but the report also shows that in addition to dumping and destructive underselling "the methods of the great German houses in carrying on their business in this country, were from the first, honeycombed with corruption." The head dyers in various mills and other important customers of the dye manufacturers were directly and indirectly subsidized. The Alien Property Custodian reports that this corruption was so extensive that he came across only one American consumer which had escaped its ill effects.

"This concern, the United Piece Dye-Works of Lodi, N. J., avoided the difficulty by having all its dyes purchased by the head of the company himself, under contracts providing that no barrel or package should show the name of the manufacturer. The company was thus able to designate the dyes which its dyers were to use solely by its own arbitrary numbers, and the dyers were thus unable to determine whose dyes they were using and to whom they should look for their graft."

In addition there appears to have been an organized propaganda intended to discourage American attempts to establish a dye industry in this country. "It seems to have been regarded as the duty of a good German chemist in the United States to preach the doctrine of the invincibility of the German chemical industry, the impossible difficulty of the processes involved in the manufacture of many important dyes, and the hopelessness of procuring the necessary technically trained men and skilled labor outside of Germany."

The result of all this was that up to August, 1914, the American industry in dyestuffs and medicinals consisted of little more than a series of rather small assembling plants. Although American manufacturers had from time to time attempted to make some of the various intermediates, the industry was killed almost at its inception by German price cutting. As a result, practically the entire American industry, small as it was, operated on German intermediates, and as such existed on the sufferance and was at the mercy of the German producers.

AMERICAN PHARMACEUTICAL HOUSES

"In medicinals very little real American manufacture existed. A few of the coal-tar pharmaceutical products were produced by two American houses in St. Louis, the Mallinckrodt Chemical Works and the Monsanto Chemical Works. By far the most important factor in this field, however, was the New York house of Merck & Co., which was a branch of the world-famous firm of E. Merck of Darmstadt, and has accordingly as such been taken over. The enormous dispensing and distributing business of such firms as Parke, Davis & Co., Lilly & Co., and Powers-Weightman-Rosengarten Co., successful and efficient as it was beyond comparison with similar businesses in any other country, seems to have involved very little real manufacture, and the materials used were largely imported. There seems to have been but little, if any, German interest in this branch of the industry, except among small brokers and dealers."

The vital character of the dye industry, says the report, is not due to its financial importance, although at the outbreak of the war these dyes were absolute essentials to industry, producing, perhaps, $2,500,000,000 worth of goods annually. Its real importance rests on "the fact that the technical skill and equipment provided by a successful dye industry furnished the means, and almost the sole means, to which every nation must look for advances in the application of chemical science to practical undertakings."

THE "BIG SIX"

Recording the fact that in the opening of the year 1914 nine tenths of the dyes used in American industry came from Germany and the bulk of them from the six huge German corporations which practically controlled the business, the report discusses, in interesting detail, the ramifications of the "Big Six" in American industrial life. The six firms were: (1) *Badische Anilin und Soda Fabrik*, Ludwigshafen on the Rhine, which the report for convenience briefly designates as "Badische"; (2) *Farbenfabriken vorm. Friedr. Bayer & Co*, in Leverkusen, shortened in the report to "Bayer"; (3) *Actien-Gesellschaft für Anilin-Fabrikation* in Berlin, abbreviated to "Berlin"; (4) *Farbwerke vorm. Meister Lucius & Bruning* in Hoechst-am-Main, briefly, "Hoechst"; (5) *Leopold Cassella, G.m.b.H.* in Frankfort, and (6) *Kalle & Co. Aktien-Gesellschaft* in Biebrich.

"At this time [January, 1914] each of these six giants was represented in this country by a subsidiary American corporation. The agent of "Bayer" was Bayer & Co. (Inc.), a New York corporation, while in the Synthetic Patents Co. (Inc.), another subsidiary, was vested the ownership of the 1,200 American patents taken out by the parent house. This New York company also owned other subsidiaries, including the Hudson River Aniline Works, through which it had established its Albany factory. "Berlin" was represented by the Berlin Aniline Works, also a New York corporation. Kalle & Company were operating through a third New York corporation, also called Kalle & Company. In these three cases all of the stock of the American house was admittedly owned outright by the parent organization. All three were accordingly taken over at the outset. The great Badische Co. acted through the Badische Co. of New York, the stock of which appeared on the books to be owned by Messrs. Adolph Kuttroff, Carl Pickhardt, and their chief employees. Leopold Casella & Co. were represented by the Casella Co., also a New York corporation, the stock of which appeared to be owned by its president, Mr. William J. Matheson, and its vice president, Mr. Shaw. Hoechst operated through a New York company known as Farbwerke Hoechst, of which the stock stood in the name of its president, Mr. Herman A. Metz. Of these gentlemen, Messrs. Kuttroff and Pickhardt were Germans by birth and Americans by naturalization. Messrs. Matheson and Shaw, Americans by birth and tradition, and Mr. Metz, American by birth. An extensive investigation was instituted by my bureau of investigation under the direction of Mr. Francis P. Garvan, and as the result of a long-continued and strenuous effort it was at last shown that the ostensible ownership of the stock of these three branches was not genuine but that each remained in fact owned by its German progenitor. As will hereinafter appear in the detailed accounts of these proceedings, each of these three companies has also been taken over."

GERMAN INDUSTRIAL CAMOUFLAGE

The report also points out that up to about 1910 all of the great German houses shipped their goods to their American representatives on a consignment basis, the representatives being paid wholly by commission. The prosecution, in 1912, of an officer of the Farbenfabriken of Elberfeld (later Bayer & Co., Inc.) for some of the corrupt practices in the way of bribing buyers, gave an insight into the German industry, and showed that it might be attacked under the Sherman law, as a conspiracy in restraint of trade. Suits were commenced against most of the American representatives.

"The institution of these suits, which were subsequently settled, resulted, in at least two cases, in a transfer by the Germans of their stock in the American company to the officers of that company. In the case of Badische Co., the stock of which was already in the names of the American representatives, it was only necessary to change the basis of the business from consignment to sale. This was done in all the cases, so that the German house might appear not to be doing business in this country through its representative, but to be merely selling to an apparently independent American corporation. There was on the surface no apparent reason why these transfers should not have been genuine. Each German house really controlled the situation with reference to its agent because it could instantly ruin its agent's business by withdrawing supplies. Accordingly, for a considerable period these houses escaped more than mere general suspicion, and it was not until the Bureau of Investigation of my department had acquired considerable familiarity with German methods of comouflage that the true situation could be disclosed."

Then follows a description of the various devices resorted to by many of these German concerns after the war started, to prevent the chemical industry of the United States from aiding the Allies, and the close relationship between these concerns and the imperial German propaganda, is touched on.

"At the time when I took office, it, of course, became the duty of all companies in which any alien enemies held stock to report such ownership. About half of those American chemical enterprises which are now known to be German owned complied more or less promptly with this requirement. The rest mostly relying on pretended transfers by which the stock had ostensibly been put in the hands of American citizens, paid no attention to the act until the activities of the Bureau of Investigation had disclosed the true facts. In some cases, however, the camouflage which concealed the true ownership was of a much subtler and more effective description. In the case of more than one of the companies which promptly reported themselves as entirely German owned, measures had been taken to transfer to companies which were presumably beyond the reach of the Trading-with-the-Enemy Act, the essential value of the German property and business."

BAYER & CO.

Particularly interesting to the medical profession is the custodian's report of the methods of Bayer & Co., Inc.:

"This company at an early date reported all its stock as held by one of the officers, Mr. Seebohm, for three trustees who in turn held for the benefit of the German parent house. It was, on the whole, the most important of all the German branches. Besides representing, as sales agent, one of the three equal giant concerns at the head of the German industry, it was the only German branch which had established any considerable manufacture in this country. Through the purchase of the stock of the Hudson River Aniline Works, it had acquired and greatly expanded a considerable plant near Albany, N. Y., in which it produced a few of the simpler coal-tar colors and considerable quantities of pharmaceuticals, especially the most valuable single product of the German house—the drug known throughout the world by its trade name of Aspirin. This was a patented coal-tar product on which enormous profits had been made. Practically the entire management of this company was in the hands of German subjects. The leading spirit, Dr. Hugo Schweitzer, was, as has been stated, among the most ardent propagandists and German agents in the country. The Albany plant represented the expenditure of many hundred thousand dollars, and the enterprise was exceedingly flourishing.

"To conceal the profits for the purpose of taxation another company was organized, known as Synthetic Patents Co. (Inc.), all the stock of which was also held by the German concern, to which were conveyed all the American patents of the German house, approximately 1,200 in number, and all the real estate, including the plant. By contracts between Bayer & Co. (Inc.), and Synthetic Patents Co. (Inc.), almost all of the profits of the former were diverted to the latter in the form of rentals and royalties. The investigation also covered a number of less legitimate evasions of the tax laws, and resulted in the recovery of a large sum by the Treasury."

In this connection it is interesting to read that the Bureau of Investigation "discovered that the treasury of Bayer & Co. (Inc.) was one of the great sources from which German propaganda funds in this country were derived." The details of the Alien Property Custodian's report on another one of the "Big Six" has especial interest to the medical profession; namely, that relative to the Farbwerke vorm. Meister Lucius & Bruning, in Hoechst-am-Main, referred to more briefly by the custodian as Hoechst.

THE FARBWERKE-HOECHST CONCERN

"The American branch of the great Hoechst Co. had for many years been conducted by Mr. Herman A. Metz. Prior to 1912, the New York corporation was known as H. A. Metz (Inc.), and a majority of its stock was always owned by the parent house. In that year the German company took over all but 10 shares of the minority stock which had previously stood in the name of Mr. Metz, leaving him the record owner of these 10, the only shares not held by them. At the same time the name of the New York corporation was changed to Farbwerke-Hoechst, so that the value of the good will might be firmly fixed in the German name. At about this time the antitrust proceedings above referred to were commenced against these companies also. Mr. Metz settled for $40,000 the suit commenced against his company, and proceeded to make strong representations to the German house to the effect that the stock ought to be owned by him so that it could be asserted that the German house was no longer doing business in America. A prolonged negotiation ensued, the Germans being very reluctant to make any change. At last in the summer of 1913 it was arranged that the 1,990 shares held by the German concern should be transferred on the books to Mr. Metz; that in return he should execute a demand promissory note without interest for the sum of $597,000; that the note should be delivered to the German company and the stock, together with a suitable transfer properly executed, should be deposited to the sole order of the German concern in a Montreal bank, as security for the note.

"At this time and for many years previous the American company had been operating under a contract by which the German house appointed it its sole American sales agent and agreed to furnish it with goods in return for which the profits were to be divided according to an arbitrary scale, irrespective of stock ownership. Under this arrangement the Germans were to have one half the profits of the color business and 75 per cent. of the profits of the pharmaceutical business, which, owing to the development of salvarsan and novocaine, had become of great importance. In return, and as a check on possible overcharges by the German house, Mr. Metz was to receive a percentage of their profits on the sales to the American company. An irrevocable power of attorney was given to Mr. Metz to vote the stock owned by the German company in the New York house and an option was reserved to the German company to purchase the stock in the event of Mr. Metz's death or retirement.

"This contract was continued unaltered after the stock transaction of 1913, and under it the profits were divided as long as it was possible to remit moneys to Germany. There was also an oral understanding between the parties that the note should not be payable except out of the stock or its proceeds, and that it could not be demanded as long as Mr. Metz should remain president of the company. It will thus be seen that the whole stock dealing produced no change whatever upon the rights of the parties. After it, as before, the share in the profits of each party remained the same, power to secure and pass title to the certificates remained as before in the hands of the German company alone; the voting power remained as before in Mr. Metz's hands; in fact none of the incident of ownership was in any way affected by the transaction.

"At the outset, Mr. Metz filed reports stating the existence of the note and the fact that certain stock was deposited as security for the same, but it was not until the ascertainment of the entire history of the transaction that the proof could be obtained that the transfer was not and was not intended to be of any effect. At last, however, the investigation thoroughly demonstrated this, and the stock has accordingly been taken over by me.

"During the course of the year 1916, Mr. Metz, finding that he could no longer secure from Germany supplies of pharmaceuticals, especially salvarsan and novocaine, which formed the most profitable part of his business, determined to enter upon their manufacture in this country. Correspondence with the German house proving unsatisfactory, he sent his brother, Dr. G. P. Metz, to Germany to secure the necessary permission. This permission was refused, but the latter came home with a sufficient knowledge to permit the commencement of the work. A new company was organized under the name of H. A. Metz Laboratories (Inc.), a New York corporation, and this company commenced the manufacture of these two invaluable medicinals, which has been continued since our entrance into the war under license from the Federal Trade Commission."

Almost as interesting are the details given in the report about the Badische Company of Ludwigshafen; of the Roessler & Hasslacher Chemical Company; and the Heyden Chemical Works, and the Bauer Chemical Company, the latter known as the manufacturers of the patent medicines "Sanatogen" and "Formamint." The stock of the Bauer Chemical Company, really the property of a Berlin concern, appeared, by a fictitious transaction, to have passed into the hands of a New York lawyer, who is now under indictment for his participation in other proceedings relative to another company. The stock of Merck & Company of New York appeared on the face to be owned exclusively by George Merck, but according to the custodian's report, investigation showed that the profits of this company had always gone to the German house in a manner utterly inconsistent with the apparent stock ownership. According to the report, George Merck insists that he is really the owner of one third of this stock, by virtue of the fact that he owns 20 per cent. interest in the Merck concern of Darmstadt. The Alien Property Custodian, however, held that indirect ownership of this kind could not be recognized, and has determined that the whole of the Merck stock is enemy owned.

The report closes with a description of the corporation that has been founded, to be known as the Chemical Foundation, Inc., in which practically every American manufacturer of importance will be a stockholder. The problem of this corporation is to acquire by purchase the German patents, which in the past have formed such a colossal obstacle to the American dyestuff industry. These will be held as a trustee for American industry and "for the Americanization of such institutions as may be affected thereby, for the exclusion or elimination of alien interests hostile or detrimental to the said industries, and for the advancement of chemical and allied science and industry in the United States." The Alien Property Custodian has sold to this company, by Executive Order, for the sum of $250,000, approximately 4,500 patents. It is believed that the organization of the Chemical Foundation will constitute the most important step in the protection of the new industry. A tariff has in the past proved utterly unavailing. In the future it would doubtless prove equally so, for, as the report says, Germany has so much to gain by extending its foreign trade and destroying the industry in other countries, that it would undoubtedly give away its goods in the United States for nothing in order to recover the American market.

THE JOURNAL realizes that this attempt to abstract this intensely interesting and valuable report is far from satisfactory, but it hopes that it may stimulate physicians to go to the trouble of getting a complete copy of the Report of the Alien Property Custodian.

Steps to Eradicate Defects in Youths.—The Maryland board of education has adopted measures with a view to eradicating physical defects in the youth of the state, following the submitting of figures at a recent meeting in McCoy Hall by Dr. M. Bates Stephens, superintendent of education, showing an alarming condition among young men. Dr. Stephens showed that in the first draft call for Maryland there were 21,644 young men ranging from 21 to 31 years, of whom 9,117 were rejected as physically unfit for military service. The percentage of unfit was entirely too high and could be greatly reduced by preventive measures. Greater stress on school sanitation, proper schoolhouse architecture, mandatory medical school inspection, instead of the present optional law, and larger provision for physical education in the schools, would be no small contribution toward better health conditions. Dr. William Burdick, Baltimore, supervisor of physical education, reported that the federal government has allotted $6,000 to Maryland to be expended in maintenance of a course of hygiene in the normal schools. He also reported that a beginning has been made to adjust the daily program so that physical exercise may be given regularly.

Correspondence

THE FOXHALL FOSSIL HUMAN JAWBONE

To the Editor:—In the year 1867, a Dr. Robert Hanham Collyer published an account of a fossil human jawbone which was found at a place called Foxhall, near Ipswich. In the days when this specimen was discovered, it was regarded as being in every way improbable that the human race was in existence in the Pliocene period to which the jaw was referred. But our knowledge has now greatly advanced, and we have now found flint implements at the same geological horizon at which the Foxhall jaw occurred. Prof. Arthur Keith, of the Royal College of Surgeons of England, and I are therefore anxious to know the whereabouts of Dr. Collyer's specimen so that it may be examined afresh in the light of our present knowledge. But, unfortunately, we cannot come on traces of it. It appears that Dr. Collyer was registered, June 23, 1868, with the General Medical Council in London, the qualification being M.D., Medical College, Pittsfield, Mass., 1839; and in 1898 his name lapsed from the Medical Register. We understand that the American Medical Directory states that the college from which, apparently, he obtained his degree is described as the Berkshire Medical College, Pittsfield, Mass., and that this institution is classed with those which are extinct or merged with other colleges. These details have been given me by the registrar of the General Medical Council in London, who has suggested that I should write to you in the hope that you may be able to give me some information in regard to medical practitioners who obtained this qualification at the time when Dr. Collyer obtained his. If you could let me know where and when Dr. Collyer died (it seems clear that after leaving England he returned to America) and if any of his relations are still living, I would be most grateful.

This is a matter of scientific importance and one in which, as the first discoverer here of the flint implements of Pliocene man, I am deeply interested, and this is my excuse for troubling you in this manner. I may say that I have put advertisements in the London *Times*, *Nature* and *Royal Microscopical Journal*, regarding the Foxhall jawbone, and the London *Illustrated News* is this week publishing an illustrated account of the discovery.

J. REID MOIR, One House, Ispwich, England.

[COMMENT.—See editorial with the same title, this week, page 1159.—ED.]

CONTRIBUTIONS FOR BELGIAN AND FRENCH PHYSICIANS

To the Editor:—With this I beg to acknowledge the subjoined subscriptions in cash and also gifts of instruments. The cash was forwarded early last January, half to Dr. Antoine Depage for the Belgians, and half to the treasurer of the Comité d'Appui des Réfugiés de Professions Libérales for the French physicians.

The instruments donated in this list consisted of 180 entries, and the value is $368.85. Some of them were in sets, for example, a set of ear instruments, laryngeal instruments, postmortem instruments, and instruments for amputations. The number, therefore, is well above 200. These have been recently sent by Messrs. George P. Pilling & Son of Philadelphia, to whom my sincere thanks are due for the great care and trouble that they took in repairing, sharpening, packing, and finally forwarding the instruments to the agent of the Belgian Relief in New York. The value in money of their services they have declined to state, but it is, as in the case of the other instrument makers, whose equal generosity I have heretofore acknowledged, a very substantial contribution.

As this practically closes my very willing and delightful service in this matter I beg to say that all told I have received in cash $2,764.88. Of this, $100 was specifically for the Belgian physicians. The remaining sum was divided equally between the Belgian and French physicians. The total value of the instruments was $4,728.85, making a grand total of money and instruments of $7,493.73.

I have not yet received from Dr. Depage the number of the Belgian physicians who have been relieved, but I have from the French committee a complete list of names of physicians and hospitals that have been assisted, with the exception of the last $70. This list numbers seventy-seven, to which are to be added those that have been assisted by the last dispatch of money and of instruments, and is to be more than doubled by the number of Belgian physicians who have been assisted by us.

In the name of our suffering confrères of France and Belgium, I beg leave to thank the profession, and in addition a few friends outside of the profession who have generously aided us. Imagine yourself in the places of those poor desolated homes and you can then possibly realize, at least in part, the thankfulness they entertain for this help.

W. W. Keen, M.D., Philadelphia.

SUBSCRIPTIONS IN CASH

Dr. R. M. Ellyson, Washington, D. C.	$ 5.00
Dr. J. T. Bottomley, Boston	10.00
Dr. J. H. Bristow, Portland, Ore.	10.00
Dr. Floyd W. McRae, Atlanta, Ga.	25.00
Dr. R. L. McCreery, Manville, Wyo.	5.00
Dr. M. Manges, New York	50.00
Mr. Louis A. Bauer, Washington, D. C.	10.00
Dr. W. W. Keen, Philadelphia (third contribution)	25.00
	$140.00

DONORS OF INSTRUMENTS

Dr. Frank Taliaferro, Carlisle, Ohio; Dr. M. Manges, New York; Dr. James C. Bloomfield, Athens, Ga.; "Anonymous Donor," Chicago; Dr. John R. Williams, Rochester, N. Y.; Fred. Haslam & Co., instrument makers, Brooklyn.

MEDICAL MEN SHOULD BE SENT HOME PROMPTLY

To the Editor:—Medical units, after closing up the hospitals, are held up over in France for weeks and months, which is an outrage. Medical men certainly have made the greatest sacrifice, I think. Men with good incomes (from five to ten thousand dollars) have taken positions in the Army for eighteen or twenty-four hundred dollars to help a good cause along, and now they are treated shabbily. When the units are closed, they are sent to the seashore awaiting transportation, while thousands and hundreds of thousands of privates are sent over, but the professional man simply waits for transportation. Why should not doctors (in fact all professional men, who have a great deal to lose "by being kept idle") be sent over promptly? It is certainly the rankest mismanagement to keep men over there for six to eight weeks who have nothing to do, while if they were home, where they are generally needed, they could do good and valuable work. The War Department certainly should be stirred up. The medical men, I am sure, are willing to go on any kind of a ship, and travel third or fourth class, as long as they can get home.

J. H. Carstens, M.D., Detroit.

PROTEST INCREASE IN TAX UNDER NARCOTIC LAW

To the Editor:—I am writing to ask if our Association cannot make a concerted objection to the extra tax which the government has put on us, especially to its failing to credit the $0.50 paid under the old law on the amount demanded by the new law. For example, I paid $1 for the year ending June 31 next, $0.50 of which, of course, applied to the half year we are now in. At the revenue office I was told that the ruling was that no credit could be given for this, and consequently I paid the $1.50, the amount the new law requires for six months. I feel that this is an imposition, and as such, remonstrance should be made in such a way as to be felt.

Henry E. Hale, M.D., New York.

Mind and the New-Born.—The mind of the new-born infant is less in evidence than that of the new-born chick.—Lay.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

NIKOLSKY'S SIGN—EPIDERMOLYSIS BULLOSA—PEMPHIGUS FOLIACEUS

To the Editor:—Please explain what is meant by Nikolsky's sign in dermatology. If I understand it, the phenomenon consists of a very loose connection between the epidermis and corium, allowing the epidermis to be very easily abraded. Please state the skin disorders with which it has been found to be connected, and indicate where and when it was first referred to. I have a case of an adult who for the past two years has had a condition similar to the symptoms of epidermolysis bullosa, excepting that no bullae develop at the site of injury. However, the epidermis is so readily abraded that he has a large number of denuded areas with weeping. Within a short time these become covered with a thin crust before healing. Should you be able to locate similar conditions in medical literature, I should be glad to have the references.

R. A. C. Wollenberg, M.D., Detroit.

Answer.—Nikolsky's sign has been described as "a condition in which the outer layer of the skin is easily rubbed off by slight injury." Sutton speaks of Nikolsky's sign in connection with his description of pemphigus foliaceus. Stelwagon, under the same head, refers to Nikolsky's "Contribution to the Study of Pemphigus Foliaceus of Cazenave" (Thèse doctorat [Kief], 1896) in which Nikolsky refers to seventeen cases of the disease reported by various authors whom he names. Stelwagon gives an extensive bibliography. According to Pusey, Cazenave first described pemphigus foliaceus in 1844.

Our inquirer does not give sufficient information on which to base a diagnosis. Failure to develop bullae at the site of traumas would seem to rule out epidermolysis bullosa; and the other characteristics of the case as far as given, with the easy abrasion of the epidermis as described by Nikolsky, might point to pemphigus foliaceus.

PETROLEUM POISONING

To the Editor:—I have a patient, a man, who drives an oil wagon and handles several hundred gallons of gasoline, distillate and kerosene daily. He has recently developed peculiar symptoms consisting of vertigo, throbbing of the temples, lassitude and loss of appetite. After examining him thoroughly I can find nothing which would cause these symptoms. Can you give me any information on the possibility of poisoning through inhalation of gasoline fumes?

Ivan W. Keith, M.D., Beaumont, Calif.

Answer.—This question was discussed in Queries and Minor Notes, Nov. 15, 1913, and July 28, 1917. In brief, the general symptoms of petroleum poisoning are headache, dizziness, accelerated heart action, labored respiration, collapse, stupor, unconsciousness and, more rarely, convulsions. Sometimes there is a rise of temperature. In case of actual collapse it is necessary to use the usual restorative measures in the form of warm baths, cold effusions and the usual respiratory and cardiac stimulants. It would seem desirable that in the case of a man particularly susceptible to symptoms on inhalation of the fumes of petroleum products, he find an occupation which would not subject him to this hazard.

The subject has been more fully discussed in an article by J. G. Johnson on the "Toxic Effects of Gasoline Fumes," *Canadian Medical Association Journal*, February, 1913.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Arkansas: Little Rock, May 13. Sec. Eclectic Bd., Dr. C. E. Laws, 803½ Garrison Ave., Ft. Smith; Sec. Regular Bd., Dr. T. J. Stout, Brinkley.

Georgia: Atlanta and Augusta, June 5-6. Sec., Dr. C. T. Nolan, Marietta.

Hawaii: Honolulu, May 12. Sec., Dr. J. R. Judd, Beretania St., Honolulu.

National Board of Medical Examiners: Philadelphia, June 2-7. Sec., Dr. J. S. Rodman, 1310 Medical Arts Bldg., Philadelphia.

Nevada: Carson City, May 5. Sec., Dr. S. L. Lee, Carson City.

New York: Albany, Buffalo, New York and Syracuse, May 20-23. Mr. George M. Wiley, director, Exam. and Inspections Div., State Edu. Bldg., Albany.

North Dakota January Examination

Dr. G. M. Williamson, secretary of the North Dakota State Board of Medical Examiners, reports the oral, practical and written examination held at Grand Forks, Jan. 7-10, 1919. The examination covered 13 subjects and included 106 questions. An average of 75 per cent. was required to pass. Of the 3 candidates examined, 2 passed and 1 failed. Two candidates were licensed through reciprocity, and 1 candidate, a graduate of the University of Pennsylvania in 1873, received a special license on account of forty-five years of successful practice. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Detroit College of Medicine and Surgery	(1916)	81
Barnes Medical College	(1911)	79
FAILED		
College of Physicians and Surgeons, Baltimore	(1882)	54.5

College	Year Grad.	Reciprocity with
LICENSED THROUGH RECIPROCITY		
Chicago Homeopathic Medical College	(1889)	Minnesota
University of Minnesota	(1912)	Minnesota

Ohio December Examination

Dr. H. M. Platter, secretary of the Ohio State Medical Board, reports the oral, practical and written examination held at Columbus, Dec. 3-5, 1918 The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass Of the 20 candidates examined, 15 passed and 5 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Georgetown University	(1918)	90.3
Rush Medical College	(1918)*	84.2
Johns Hopkins University	(1918)	87.5
Harvard University	(1918)	89.9
Columbia College in the City of N. Y.	(1894)	77.1
Cleveland College of Physicians and Surgeons	(1910)	84.5
Ohio State University College of Medicine	(1918)	85.1
Western Reserve University	(1918)	83.1
Jefferson Medical College	(1918)	77.4, 82.2
University of Pennsylvania	(1918)	88.5
University of Pittsburgh (1917) 89.6; (1918) 83, 85.5, 87.8.		
FAILED		
Atlanta Medical College	(1890)	46.8
Homeopathic Hospital College	(1892)	†
Meharry Medical College	(1918)	†, †, 69.7

*Received certificate for four years' work. Degree will be granted on completion of hospital internship.

†No grade given.

Irregulars and Their Methods.—Irregular practitioners do not prosper because their therapeutic methods are successful, but because of the advantage they take of sick people. Why not put an end to the taking of this advantage? It is now unethical to guarantee a cure; why not make it unlawful as well by the enactment of special legislation? The taking of money in advance of treatment should constitute *prima facie* evidence of fraudulent intent. If it were accepted after unsuccessful treatment, the failure to cure should then constitute proof of fraud, assuming the previous guarantee. Restitution of the fee should be included in the penalty.—*Weekly Bulletin*, Department of Health, New York City.

Book Notices

Quarterly Medical Clinics. A Series of Consecutive Clinical Demonstrations and Lectures. By Frank Smithies, M.D., F.A.C.P., Associate Professor of Medicine, School of Medicine, University of Illinois. Volume 1, Number 1. Paper. Price, $1.50. Pp. 188, with 42 illustrations. St. Louis: Medicine and Surgery Publishing Company, Inc., 1918.

The success of the Murphy Clinics popularized this form of medical literature. This venture was followed by the Medical Clinics of Chicago, subsequently the Medical Clinics of North America, the Surgical Clinics of Chicago, and others. A recent recruit is Smithies' Quarterly Medical Clinics. The preface modestly points out that students and visiting physicians had suggested to Dr. Smithies that his clinics be presented in permanent form. The distinctive feature of these clinics, differing from those mentioned, is the addition to each case report of detailed notes on clinical and laboratory procedures describing the elementary laboratory and clinical methods used by the author or his laboratory assistants in reaching a diagnosis. The descriptive titles on the cases seem unnecessarily verbose; for example,

"Mr. C. D., an Adult Blacksmith, with a Previous History of Enterocolonic Amebiasis, Walked into the Hospital Complaining of Severe Frontal Headache, Mental Cloudiness, and Feeling as Though he had Fever." This is the title. The case, it develops, was one of diffuse, acute cerebrospinal meningitis, the treatment of which consisted of good nursing, "preliminary purge with 2 ounces oleum ricini; urotropin, 10 gr., every two hours in an attempt to combat cerebrospinal infection." Incidentally, cultures from the spinal fluid on two examinations had been negative. The routine form for each case is the presentation of history, environment, preliminary physical examination, special examinations, positive findings, differential diagnosis, usually a general discussion of the subject, including the pathology of the disease, and finally treatment. In general, the therapeutic methods used are rational and simple. In places the language of the author is somewhat unusual; for example, "The 'hard boiled egg' type of drunkard rarely reacts to the psychology of 'drink-cure' institutions; he comes to look upon 'taking the cure' as part of the price he must pay for the joys of his jag"; and elsewhere, "In effecting a cure himself he has about as great a chance as he would to buck a First Ward 'crap' game." This presumably adds local color.

The Unsound Mind and the Law: A Presentation of Forensic Psychiatry. By George W. Jacoby, M.D., Consulting Neurologist to the Hospital for Nervous Diseases. Cloth. Price, $3 net. Pp. 424. New York: Funk & Wagnalls Company, 1918.

The author in his introduction states the irreconcilable differences that have arisen in the application of legal dicta of responsibility in mental disease. He makes no effort to reconcile them. To attempt to do so at this time would be not only useless but also untimely. He contents himself with urging the physician, on the one hand, to obtain some juristic knowledge and, on the other, those who are charged with the administration of the criminal law to equip themselves in psychiatry to such an extent that they may be able to understand the principles underlying opinions given by physicians.

The discussion of the general relations of jurisprudence and psychiatry opens with a historical retrospect showing the genesis of the varying views in relation to responsibility in mental disease as they have been formulated from the earliest times. The author points out that psychiatry has had to travel a difficult road, and that long after inductive methods of observation had taken root in general medicine, psychiatry was still looked on as an intellectual science. He leaves us in no doubt as to his position when he says that the term "mental" disease is misleading, conveying as it does a notion of disease of the mind as opposed to a disease of the body. It would be profitable if the writer's words were hung as a motto in every hospital where sick people are treated: "Mental disease is bodily disease, and differs from other forms of such affliction merely by reason of the fact that it has its seat in the brain. Not every brain disease is mental disease. But every mental disease is brain dis-case even when no anatomical lesion of the brain is discoverable." The earliest writers, notably Hippocrates, had this conception of mental disorder, but it was buried under the mass of superstition which developed in the middle ages.

One of the most satisfactory chapters is that devoted to the examination of the insane. The second half of the book deals with psychiatric expertism and consists of a discussion of various forms of mental disease together with a description of their symptoms and differential diagnosis and a discussion of their forensic aspects. This part will be found to be of special value for the legal profession, as it succinctly and accurately tells what is meant by a diagnosis in mental disease and how it is arrived at, and the general principles on which responsibility should be assessed in each group of disorders.

Jacoby leans strongly toward the idea of modified responsibility in mental disease. It is difficult to understand how a psychiatrist could reach any other conclusion, but unfortunately the application of such doctrine at this time is purely academic. There is in the majority of jurisdictions in this country no provision for carrying it out. The statute prescribes certain penalties for certain cases, and if the defense of insanity is successfully made there is no place for the patient to go excepting to an asylum. If, on the contrary, it is not maintained, the penitentiary and the gallows are the only alternatives. In those states which still maintain capital punishment, a sort of modified responsibility is obtained by the substitution of life imprisonment in capital cases when there is a doubt of mental capacity. Whether the substitution of life imprisonment for the death sentence is in effect a modification of responsibility is perhaps open to argument.

The author has produced an excellent book—one that was needed at this time, and one that will do much toward putting modern psychiatry in the possession of those who have charge of the administration of the criminal law but who are not possessed of any technical knowledge of the subject.

Genitourinary Diseases and Syphilis. By Henry H. Morton, M.D., F.A.C.S., Clinical Professor of Genitourinary Diseases in the Long Island College Hospital. Fourth edition. Cloth. Price, $7. Pp. 807, with 330 illustrations. St. Louis: C. V. Mosby Co., 1918.

If one favors the idea of embodying urology and syphilology in one treatise, then Morton's book must be regarded as a most satisfactory one. All the chapters are written with equal care, and the presentation of the matters discussed is concise and yet perspicuous. A feature worthy of mention is the endeavor of the author to give proper credit to other medical writers for their contributions to the advance of the specialty. In forty chapters devoted to urology, the author covers practically everything that is worth knowing in this line of work. The modern methods of examination and diagnosis are fully described, and are illuminated by numerous illustrations, among which the colored plates are deserving of praise. The generally accepted tests of elimination are described, and valuable hints are given concerning their application and the interpretation of the results. The discussion of gonorrhea is complete; it will be a welcome guide for the practitioner. The sober attitude taken by the author toward operations for malignant growths of the bladder will be appreciated by every surgeon who does not permit his ambitions to run riot with his judgment. Radiotherapy of the bladder and the clinical features of vesical diverticula would seem to deserve more than the somewhat scanty discussion given these topics. Twelve chapters are devoted to the clinical aspects of chancroid and syphilis. Special stress is laid on the diagnosis, and the outline given in the form of tables is particularly instructive. The most important types of clinical manifestations are presented by the aid of many illustrations, among which the colored plates again deserve special recognition. The modern laboratory tests are not only described in reference to their technic, but are also explained from a biologic and biochemical standpoint. The therapy is presented clearly. Of great value is the discussion of the various methods with reference to the state of the disease and the general condition of the patient. The dangers and untoward effects of the modern energetic treatment are pointed out with great precision, and valuable hints as to their prevention are furnished.

Social Medicine, Medical Economics and Miscellany

Health of Workers and the Eight Hour Day in Wool Manufacturing

The National Industrial Conference Board Research Report No. 12, just issued, discusses the hours of work as related to the output and to the health of workers in wool manufacturing. Statistically the report is based on replies from 111 establishments employing 71,595 workers, supplemented by reports of field agents. All together, the report covered 126 establishments employing 47 per cent. of the total number of wool mill workers in the United States. With the question of output we are not particularly interested, although it is worth noting in passing that the board concludes that the adoption of a fifty-four hour schedule in the wool manufacturing industry has in a large number of cases resulted in a reduced output. Regarding the effect on the health of the workers, the investigators found that on account of lack of satisfactory records and careful observation of health conditions, conclusive judgment was impossible and only approximate deductions could be made. Of the fifty-seven establishments reporting definitely on health conditions, fifty stated that the shortening of the hours of work had no significant effect; three reported good effects, and four reported decided improvement. Each of the seven reporting good results had had a previous schedule of fifty-eight hours; those in which the weekly reduction amounted to only two hours reported no apparent change in health conditions. There appears to be no strictly occupational disease in the wool manufacturing industry. Suction shuttles are not allowed in wool factories as they are in cotton mills. Animal dusts are considered less harmful than the vegetable dusts evolved in cotton and flax manufacture. The dirt given off in wool sorting, rag sorting and grinding is irritating to the respiratory tract, and in extreme cases causes "shoddy fever" with symptoms similar to influenza. The greater part of this dust has been eliminated in the more modern mills. The carbonizing process is more or less hazardous on account of the dust and fumes. Anthrax, in its pulmonary form known as "wool sorter's disease," is apparently extremely rare in the wool industry in this country. Of 132 deaths from anthrax recorded in the twenty-four registration states from 1910 to 1915, only one of the victims had been engaged in woolen manufacturing. The president of a large woolen mill states that in fifty years' experience he has never had a case in his mill and has known of but one case. Most of the anthrax in this country is found among those working in hides and dry hair rather than wool. In striking contrast to the condition in this country, the Seventeenth Abstract of Labor Conditions of Great Britain reports that of 150 cases of anthrax in Great Britain, from 1900 to 1913, sixty-six were in the wool manufacturing industry. The comparative freedom of American wool sorters from this disease is largely due to the relatively small amount of wool imported from regions where anthrax is prevalent. The heat, humidity and poor ventilation found in the weaving sheds results in coughs, colds, rheumatism and pulmonary diseases, while the chemicals used in scouring and dyeing are also responsible for some industrial disease. As is to be expected, tuberculosis among wool workers has a higher rate than the average, the percentage of the total number of deaths for the three decades from 25 to 55 being 41.7, 35.3 and 16.7 for wool mill operatives as against 30.8, 25 and 15.6 for all manufacturing and mechanical groups. In pneumonia also the rate among wool mill operatives is markedly higher, being 12.5 and 13.2 for the decades from 25 to 45, as contrasted with 7 and 9.5 for the same decades in all manufacturing and mechanical pursuits. Strangely enough, however, in the decade from 45 to 55 the percentage of deaths from pneumonia to all deaths in the wool mill operatives class is only 6.1, while in all manufacturing and mechanical pursuits it is 9. On the other hand, the percentage of deaths from heart disease and nephritis is less among wool workers from 25 to 45, but higher from

45 to 55 than it is among all manufacturing and mechanical pursuits. Regarding accidents, while there are few conspicuously dangerous machines, there is a relatively large number of accidents among workers in the wool industry, the insurance rate being 83 cents per $100 for wool spinners as against 92 cents for cotton spinners and weavers and 30 cents for silk manufacturing. This, in the opinion of the board, is due to complex and crowded arrangement of the machinery, to unguarded machinery, to slippery floors and to carelessness on the part of workers themselves. The final conclusions are that the adoption of a fifty-four hour schedule has had an unimportant effect on the health of workers; that the occupation is comparatively free from strictly occupational diseases; that it has a distinctly high death rate from tuberculosis and pneumonia caused in part by the high temperature and humidity characteristic of certain processes in the industry, and that the high death rate from tuberculosis among wool mill workers would indicate that conditions within the industry are a contributing factor.

Ireland and a Ministry of Health

T. Hennessy, F.R.C.S.I., D.P.H., Irish secretary of the British Medical Association, discussing the subject of Ireland and a ministry of health in the *Dublin Medical Journal,* Feb. 1, 1919, says that in an experience of almost twenty years in the County Tipperary Dispensary as a physician in the Poor Law Medical Service he found that between 50 and 70 per cent. of the Irish population receive free medical treatment as "poor persons." This abuse of dispensary privileges, he says, is not so much the fault of the Irish people as of legislators, who are too indifferent to make themselves acquainted with the medical needs of the country, or to take the advice of those who can best give it. He believes that Ireland is more in need of legislation providing for a ministry of health than any other country of western Europe. The main principles governing the establishment of such a ministry should be as follows: It should take over the complete control of all the health services belonging at present to the different government departments; its administrative functions should be carried out by a central body called the board of health, presided over by a minister of cabinet rank; to this board should be transferred, in Ireland, (*a*) the duties of the Local Government Board with regard to health; (*b*) the duties of the Home Office with regard to the inspection of workshops and factories, and those of the board of trade, for example, medical inspection of ships; (*c*) the Irish Insurance Commission; (*d*) administration of lunacy laws; (*e*) health functions of the Privy Council with regard to midwives, etc.; (*f*) Education Extension Act, 1915, and medical inspection of schoolchildren; on the board of health there should be members of the medical profession representing, in equal numbers, the clinical and preventive sides of medicine, and there should be a consultative council for giving advice and assistance in all health matters.

For local organization, the country should be divided into suitable administrative areas which would require the services of whole-time administrative medical officers, both clinical and preventive. In each county and borough there should be county and borough health committees, composed of dentists, pharmacists and certain lay persons. There should also be district health committees, the functions of which, as well as the duties of the medical officers and the dispensary physician assistants, are outlined by Hennessy. For each area the county health committee should established hospitals, including, when necessary, sanatoriums, clinics (including natal and prenatal maternity, and child welfare), nursing schemes, and medical and dental inspection of schoolchildren. There should also be provided pathologic laboratories and facilities for consultation and specialist services.

Though the reports of the Local Government Board for the three years preceding 1918 show that an average of 610,322 new cases were attended and registered as poor persons by the dispensary physicians, about one third of whom were attended at the patients' homes, Hennessy says that this does not represent half of those attended, on account of records not having been made of the cases. The amount of work thrown on the dispensary physicians is very large, and for it they are very poorly paid. The average population for whose "public health" the dispensary physician is responsible is between 4,000 and 5,000, and his salary is about £15 ($75) a year. For the actual work and liabilities for the treatment of about two and a half million people in Ireland in 1917, the dispensary physicians received £109,604, or an average of approximately £130 a year.

Remarkable Case of Personation of a Dead Physician

A curious case of personation of a dead physician for many years came to light recently in a British court. In the fashionable town of Chislehurst, Kent, a man practiced under the name of James Allan and enjoyed an excellent position. He was surgeon to a number of charitable institutions and to the local cottage hospital. He moved in the best medical circles, for he was also a fellow of the Royal Society of Medicine, a member of the West London Medical Society, and the author of several medical papers, some of which had appeared in the transactions of the West London Medico-Chirurgical Society. Among these were "Twelve Cases of Tracheotomy in Young Children with Nine Recoveries," 1899, and "Treatment of Malignant Disease by Electric Currents of High Potential and Frequency," 1902. In the Medical Directory (which it must be remembered is not an official book but is issued by a firm of publishers), his name appeared from 1901 onward as James Allan, M.B., C.M., of Edinburgh, the exact name and qualifications of a physician who practiced in Bradford and died in 1898. The deception was discovered in this way: The defendant was largely instrumental in forming a branch of the V. A. D. (Voluntary Aid Detachment, an institution formed for training women in duties of nursing so as to be able to help in case of emergency). When the war broke out, the V. A. D. was able to provide an almost unlimited amount of nursing and other help for the hospitals that were formed all over the country. The defendant was appointed medical officer of the V. A. D. hospital at Chislehurst, and also assistant county director for the V. A. D. in Kent. For this work he was decorated by the government, received the distinction of O.B.E. (Order of the British Empire). But this was his undoing. When the usual annual form was sent out by the Medical Directory to all physicians on its list, he returned his name with the distinction O.B.E. added to it, and this also appeared in the newspapers and was seen by the registrar of the General Medical Council whose duty it is to supervise the Medical Register (the official list of all physicians). On looking at this he found that there was no such practitioner registered. The history of the defendant was as follows: He was the son of a farmer at Lurgan, Ireland. At 18 he went to Glasgow, where he was a shop assistant and studied medicine. He remained in Glasgow until about 1893 and then became an assistant to physicians in London until about 1901. Then he went to Chislehurst, where he has practiced ever since. About the time he began to practice at Chislehurst the sister of the late Dr. James Allan received a request from a person in Glasgow asking if she would dispose of her brother's diplomas and saying that he had a hobby for collecting diplomas. The sister did not part with the diplomas. The writer of the letter turned out to be a physician practicing in Glasgow who knew the defendant well. When the case came into court, Lord Chilston, director of the Kent V. A. D., was called to give evidence of the character of the defendant. He spoke highly of the work of the defendant in connection with the Red Cross Hospital at Chislehurst, of which the defendant had had charge. Of the 2,161 patients who had passed through it, only one had died, and that was a patient with pneumonia. Canon Dawson, rector of Chislehurst, said that the defendant had attended his household for sixteen years successfully and skilfully. The defendant was ordered to pay the maximum penalty of $100, and $50 costs. Many cases of imposture in connection with the medical profession have occurred, but it is doubtful if ever an impostor enjoyed such a respectable position in the eyes not only of the public but also of the profession.

Medicolegal

Using and Submitting Reports of Assistants

(Mesmer & Rice et al. v. Industrial Accident Commission et al. (Calif.), 173 Pac. R. 1099)

The Supreme Court of California, in affirming an award of the Industrial Accident Commission in favor of one Wilson for injuries alleged to have been suffered by him in the course of his employment by Mesmer & Rice, says that the employers contended that the disability for which compensation was sought was due to a certain disease with which it was said Wilson was afflicted, rather than to the injury received by him. After the taking of the evidence before the referee, it was agreed, or understod, that Wilson was to submit himself to an examination by the physician of the commission, who was to take whatever measures he might deem necessary to reach a conclusion, and that his report was to be made to the referee, to be used by the commission in arriving at a conclusion. The report of the physician was presented, accompanied by the reports of two other physicians whom he had in consultation with him in the case, one of which latter reports was a report of certain symptoms as shown by an examination, and the other was simply a report of the result of a Wassermann test, the answer being "negative." The employers complained of the physician of the commission submitting to it with his own report, and as a part thereof, the reports to him, which were thus made evidence in the proceeding. But it could not fairly be disputed that, in view of the understanding that the physician of the commission was to take whatever measures he deemed necessary to reach a conclusion, he had the right to employ assistance to make certain observations as to Wilson, including a serologic examination, and to report the result for his information in observing Wilson, and in coming to a conclusion. This he did, and on their reports to him and his own personal observation of the case, continued for many days, he made his own report to the commission. There can be no doubt that his report was, in view of the understanding of the parties, competent evidence to be considered by the commission. The court may assume for the purposes of this decision that the written reports of the two assistants, which the physician submitted with his report, were not competent independent evidence, for the consideration of the commission, and that the application of the employers before the award was made, that such other reports should be stricken out and withdrawn from the record, should have been granted. But the failure of the commission to reject the incompetent evidence could not affect its jurisdiction to make the award, and independent of the evidence alleged to be incompetent there was ample evidence to support all the findings. At most, there was refusal on the part of the commission to strike out incompetent evidence which was merely cumulative of other evidence, and in no way essential to support the conclusion of the commission. It may further be noted that, in view of the report of the physician of the commission, the other reports were of no substantial importance. Wherefore the award is affirmed.

When Fees Paid in Advance May Be Recovered

(Bucklin v. Morton (N. Y.), 172 N. Y. Supp. 344)

The Supreme Court of New York, appellate term, first department, reverses a judgment that dismissed the complaint in this action to recover money paid in advance by the plaintiff to the defendant for medical services to be rendered by the defendant as a physician at his office and which the plaintiff could not receive on account of his having become very ill and being unable to leave his house to go to the defendant's office. The court says that the rule governing cases of this character has been well stated as follows:

"The principle underlying these cases is that the contract was entered into by the contracting parties on the implied condition of the continued ability of the party who is to render the services to perform, and that, when unable to perform, because of sickness or physical or mental incapacity proceeding from no wilful or deliberate conduct of the party, such inability is in consequence of an act of God, and excuses performance. . . . The obligation of the party who is to receive the services to pay is conditional on the obligation of the party who is to render the services to perform, and vice versa. If the contract of employment is to continue operative and binding, those interdependent obligations must continue to exist; and, if one party is excused from the performance of his obligations, the obligations of the other party must likewise come to an end."

The rule would seem to be equally applicable to both parties to a contract, in which the services to be rendered and received were dependent on the physical ability of the plaintiff to attend for treatment and of the defendant to give the treatment. In the event of illness of the defendant and his physical inability to perform, he would not have been liable for damages for breach of contract, but would have been obligated to return to the plaintiff the money paid in consideration of services subsequently to be rendered and not actually rendered. If, by reason of the defendant's inability to perform through no fault of his, the contract ceased to be binding on the defendant, it became inoperative in like manner to the same extent in the event of similar disability on the part of the plaintiff.

There was no evidence to support the contention of the defendant that the money paid by the plaintiff was paid as a retainer. It was paid in contemplation of services to be rendered, the rendition of which, by reason of the continuing serious illness of the plaintiff, became impossible. On the expiration of the period during which the monthly treatment was to have been rendered, the plaintiff became entitled to the return of the money; there being no proof of any expense having been incurred by the defendant in preparation therefor prior to the plaintiff's permanent disability. The judgment rendered in favor of the defendant must be reversed, and judgment directed in favor of the plaintiff for the full amount, with interest and costs in this court and in the court below.

What Medical and Surgical Aid or Service Includes

(Olmstead v. Lamphier et al. (Conn.), 104 Atl. R. 488)

The Supreme Court of Errors of Connecticut, in holding that the workmen's compensation act of that state imposed a legal duty on the defendant to purchase for the plaintiff an artificial leg as a part of the surgical aid or service provided for in said act, says the court was left with the bald question whether surgical aid or service includes the furnishing of an artificial leg. There is no specific provision for the furnishing of medicines or any material or apparatus required by the physician. Yet it is clear that all these are included in the term "medical aid or service." It must also be clear that all necessary bandages, materials, splints, and apparatus required by the surgeon in effecting a cure are included under the term "surgical aid or service." The fact is that Section 7, as amended by Chapter 368 of the Public Acts of 1917, is general in its terms and purposely so. In the New York act there is a specification of various things to be furnished. In Connecticut a different course was adopted, general terms being used in the act with the intention, the court thinks, to include all things which might reasonably fall within its provisions. The employer is required to furnish the employee a physician, and, in addition, "such medical and surgical aid or hospital service as such physician shall deem reasonable or necessary." This language is broad and general.

"Medical aid" is relief pertaining to the science of medicine. And "surgical aid" is relief pertaining to surgery or used in surgery. The term in its ordinary significance is not limited to the personal service of the surgeon, but includes all the means and instrumentalities used in surgery which will help effect a cure. Splints and crutches and apparatus for holding the limb manifestly are brought to the patient by the surgeon, adjusted by him, and usually paid for directly by the patient. It is part of the duty of the surgeon to prepare the stump of arm or leg for the artificial arm or leg. It is a part of his duty to adjust it. Why give the patient splints to hold the bones in place or crutches with which to walk, and regard these as used in surgery? Why supply a glass eye? Because it is the everyday duty of the surgeon to order these things for his patient, and they are included as of course under "surgical aid." There is no difference between supplying these and the artificial limb. That pertains to surgery and is used in surgery. The stump must be prepared by the surgeon to receive the artificial limb, and that must be adjusted to the stump by the surgeon. The only difference between the crutch and the artificial limb is the latter costs more than the former.

The Connecticut act contemplates the furnishing of all the medical and surgical aid that is reasonable and necessary. The purpose of this provision is to restore the injured employee to a place in the industrial life as soon as possible by the use of all medical and surgical aid and hospital service which ordinary usages of the modern science of medicine and surgery furnish. Humanity and economic necessity in this instance are in harmony in working for the accomplishment of the individual and of the public welfare.

"Surgical aid" is a term of technical significance and has an established meaning in standard works on surgery. The duty of the surgeon does not end with the healing of the stump. His duty continues until the artificial limb is adjusted and the patient has learned how, with the help of the surgeon, to use it properly. It would not be questioned that the entire bill of the surgeon for his services would fall under the head "Surgical Aid." It would be difficult to justify this expenditure, as well as that for bandages or ointments or other material used by the surgeon in his treatment of the patient, and not make a like expenditure for the artificial leg in connection with which these things were used.

Basis for Opinion

(Ft. Smith & Western Ry. Co. v. Hutchinson (Okla.), 175 Pac. R. 922)

The Supreme Court of Oklahoma holds, in this personal injury case, that a physician in giving evidence as an expert may base his opinion on his observation and examination of the patient, together with a history of the case as given to him, and such opinion will not be rendered inadmissible in evidence because based partly on statements made to him by the patient with reference to her condition, symptoms, sensations, and feelings when they were made to, and received by him, and were necessary to an examination and proper diagnosis and treatment of the patient's injuries.

Antiscorbutic Values of Foods.—During the late war there was considerable scurvy among the troops of the various armies; least of all along the western front. The scurvy was mainly of the latent or subacute variety, and influenced the character of some of the infectious diseases. Scurvy also prevailed among the civilian population to a degree far greater then in peace times. In infants the question of scurvy centers about the milk supply. An infant requires fully 1 pint of fresh raw milk daily to protect it from this disorder. If the milk is pasteurized, or stale, or heated for a second time, or rendered more sensitive to deterioration by means of an alkali—and particularly if more than one of these influences are operative—more than a pint is needed. The fact that there is an inverse relationship between the amount of milk consumed and the tendency to scurvy in the authors' opinion show that the poison is not an exogenous toxin and argues in favor of the disorder being primarily a deficiency disease.

Hess and Unger point out that milk does not necessarily lose its antiscorbutic value in the course of drying. If it is dried rapidly, even at a temperature of about 240 F., it retains sufficient of the protective factor to have curative value, provided, naturally, that it was fresh at the time of drying. In considering the question of destruction of this "vitamin" by heat or by alkali, the duration of exposure to the deterimental influence is of the greatest importance. Babies fed on pasteurized milk should receive an antiscorbutic from the time they are a few weeks of age, as there is no reason for allowing the negative balance of "vitamin" to continue for a longer period. A small amount of orange juice will answer the purpose, and is potent for a period after alkalinization. Its value does not reside in its laxative properties, or in its salt content, as "artificial orange juice" has practically no therapeutic effect. If orange juice is filtered, boiled, and rendered faintly alkaline it may be given intravenously without causing any slightly untoward reaction. In this way a very prompt cure can be effected.

From a pathogenic point of view, a result obtained by this route is of interest as demonstrating that scurvy can be counteracted by a therapy acting quite apart from the alimentary tract. Diuresis and catharsis do not play an important rôle in the cure of scurvy, as they may be stimulated to a high degree without alleviating the symptoms. This fact argues against regarding this disorder as essentially toxic in nature. It was found also that giving an antiseptic (sodium benzoate) was without effect. Dehydrated vegetables were ineffective in two instances studied by Hess and Unger in which an equivalent amount of fresh vegetables brought about a cure. They do not infer from this result that dehydration necessarily destroys this "vitamin." In this connection too much attention has been paid to the degree of the heating process, and too little to the more important factors —the age of the vegetables, their freshness previous to dehydration, their manner of preservation, etc. For almost a year strained canned tomatoes have been given by Hess and Unger, in place of orange juice, to a large number of infants. This substitute has been found a very effective antiscorbutic, and is well borne by babies a few weeks of age. It has the advantage of low cost and availability, and therefore is of particular value for the infants of the poor.

Fat Metabolism of Infants.—The fat of the stools of normal breast fed infants, according to the observations made by Holt and others, averaged 34.5 per cent. of the dried weight and frequently was as high as 50 per cent. The soap fat in the best stools predominated over the other forms of fat, averaging 57.8 per cent. of the total fat, as determined on the dried stool. The average stool of the normal breast fed infants showed a soap fat of 43.1 per cent. of the total fat, as determined on the dried stool, which would correspond to over one third of the total fat of the fresh stool. The neutral fat in the best stools averaged 15.9 per cent. of the total fat; in the average stool the neutral fat was 20.2 per cent. of the total fat. The amount of neutral fat is not affected by the drying process. No constant relation was shown between the percentage of fat in the mother's milk and the percentage of total fat and its distribution in the stool. With a higher total intake of fat, the fat percentage and the soap fat in the stool were somewhat increased. A range of fat absorption from 90.3 to 99.2 per cent. of the intake was found in healthy breast fed infants.

Bovine Tuberculosis in Children.—An analysis of twenty-four cases of tuberculosis in children and infants is made by Austin with special reference to the bovine or human type of infecting organism in each case. Seven of the twenty-four patients were infected with the bovine type of the tubercle bacillus. In the twelve cases in which the primary focus was noted, it was found in the right lung in six, in the left lung in two, in three cases apparently in a bronchial lymph nodule on the right side, and in one case in the intestine. One of the bronchial node cases and the intestine case had bovine infections. The corneal scratch test was not very satisfactory. Although consistently negative in rabbits with human type infection, it was not always positive in the bovine type animals.

Austin sounds a note of warning in regard to infection through cow's milk, it being generally considered that bovine infection is most likely to occur in this way. Notwithstanding that all milk sold in Chicago is supposed to be pasteurized, yet here are seven cases of bovine infection out of twenty-four cases of tuberculosis in children. This fact, he thinks, points to the necessity of home pasteurization of cow's milk.

Roentgen-Ray Intoxication.—This paper deals with the general constitutional reaction which follows prolonged exposures to the roentgen rays of the Coolidge tube. The experiments made by Hall and Whipple on dogs show the increase in nitrogen elimination and in blood nonprotein nitrogen which precedes fatal intoxication. Vomiting and diarrhea dominate the clinical picture until death, which, as a rule, follows on the fourth day. The blood nonprotein nitrogen commonly shows a marked increase (twice normal) on the day before death and often more than three times normal on the day of death. The elimination of urinary nitrogen is increased on the day following the roentgen-ray exposure and remains high until death, often an increase of 50 to 100 per cent. above the normal base line. The so-called roentgen-ray anaphylaxis or hypersensitiveness to a second properly timed roentgen-ray exposure finds no support in the authors' experiments. In fact, there is some evidence for a slightly increased tolerance to the second dose. Neither do the experiments yield any evidence of roentgen-ray nephritis.

Congenital Dextrocardia.—Three cases are cited by Willius in which this anomaly was discovered accidently. One patient presented herself for examination complaining of chest pains of the intercostal neuralgic type. A second presented herself for examination on account of a pelvic complaint. The third presented herself for examination on account of goiter. The electrocardiograms of the last two cases essentially confirm the findings recorded previously. Willius says that inversion of the deflections in Lead I is definite evidence of congenital dextrocardia with situs transversus; hence electrocardiography should be recognized as a valuable adjunct in the differential diagnosis of cardiac displacements.

Protozoal Infections of Intestines.—The incidence and behavior of these organisms in other then tropical regions and the pathogenicity and treatment of certain of the flagellates are discussed by Pollock and Pickard. They urge that all patients presenting obscure bowel symptoms, especially if anemic or achylous, should have the stools carefully searched for parasites. And it should be borne in mind that the pathogenicity and behavior of the intestinal protozoa vary under different conditions of climate, latitude, exercise, diet and medicinal treatment. The flagellates (monads) are capable of distinctly pathogenic behavior. The most satisfactory treatment they have applied to the monads up to the present is the double mercury treatment, the combined use of emetin hypodermically and arsphenamin intravenously. In a group of forty-six cases seen by the authors during the past year, with symptoms seeming to demand a careful search for intestinal parasites, nineteen, or 41.3 per cent., showed protozoal parasites, many times accompanied by other intruders.

Chronic Jaundice of Family Type.—A man and his sister presented exactly the same picture clinically. Their histories were practically the same, the man complaining only of a large leg ulcer besides the jaundice, and the sister complaining of dysmenorrhea in addition to her icterus. They were otherwise well. Johnston points out that the presence of uterine stenosis in the woman and a talipes equinus in the man may be suggestive hints of congenital factors present in both, some such factor producing hemolytic jaundice.

Blood Grouping Applied to Skin Grafting.—The clinical observations made by Shawan proved that autografts grow best. Isografts obtained from donors of the same blood group as the recipients or from Group IV donors became permanent takes and grew almost if not equally as well as autografts. Isografts where the donor and recipient were of different groups did not remain as permanent groups growths except when Group IV skin was used or when the recipient was a member of Group I. Group I recipients grew permanent skin from donors of all of the four groups and apparently equally well. Group IV skin grew permanently on recipients of all groups, but only Group IV grafts and autografts remained as permanent takes on Group IV recipients. Therefore it may be assumed that skin grafting obeys the principle of blood grouping, as in the transfusion of blood.

Diagnosis of Mitral Stenosis and Aortic Insufficiency.—The features which Goodman considers as being most in favor of the diagnosis of aortic insufficiency are: (1) displacement of the apex-beat; (2) heaving feel of the apex impulse to the palpating hand; (3) hypertrophy of the left ventricle; (4) vascular signs, i. e., marked pulsation of vessels, Corrigan pulse, capillary pulse, systolic tone in brachial, with arm above the head; (5) blood-pressure increase of pulse-pressure, marked discrepancy between the arm and the leg pressures. In favor of a mitral stenosis are: (1) loud snappy first sound at the apex unless marked by an insufficiency of the mitral valves; (2) absence of apical displacement and of cardiac hypertrophy; (3) systolic tap or shock to the palpating hand; (4) absence of vascular signs; (5) absence of any characteristic blood-pressure phenomena.

Cardiothoracic Ratio in Heart Enlargement.—The cardiothoracic ratio discussed by Danzer is based on the anatomic relationship that exists between the heart and its containing frame, the chest. Wherever a roentgen-ray laboratory exists the facilities are sufficient for this work. The method has been tried out by Danzer and others in a sufficiently larger number of cases (500 or more) to warrant its practicability and usefulness in the estimation of cardiac size, particularly in cases of moderate or early enlargement.

Arsphenamin in Cutaneous Tuberculosis.—This study deals with a group of twenty cases of various types of papulonecrotic tuberculid and erythema induratum in which arsphenamin was used with good effect by Stokes in combination with systemic regimen and roentgen therapy. Over half the cases thus treated had demonstrable tuberculosis, usually in the form of a lymphadenitis. Surgical treatment of the lymphadenitis in nine cases had not demonstrably affected the tuberculid. It would seem that the appearance or the persistence of a cutaneous tuberculid following reasonably complete surgery is an indication for a discontinuance of surgical treatment of the tuberculous focus, and the adoption of a medical means of fortifying the patient against the progress or recurrence of his tuberculous infection. The intravenous administration of arsphenamin appears to afford such a medical means of fortifying the patient's resistance to tuberculosis when combined with antituberculous hygiene and roentgen ray.

Stokes claims that arsphenamin offers an excellent means of treating selected cases of obscure tuberculosis, as evidenced by the presence of a tuberculid in the absence of a demonstrable focus. Its use in febrile, acute or rapidly progressive cases is not advised. Arsphenamin alone is apparently able to produce a striking effect on cutaneous tuberculids. Fifty-three per cent. of seventeen cases treated by Stokes have been completely cleared of lesions, and only 12 per cent. have failed to secure a definite improvement. Arsphenamin is also apparently instrumental in producing a marked constitutional improvement in these cases, evidenced especially by a gain in weight and the disappearance of the "rheumatic" symptoms. The effect of arsphenamin on the tuberculous adenitis where present is indeterminate, but probably not striking. An outdoor life, forced diet, correction of vascular abnormalities and stasis by elastic support, and careful extirpation of secondary foci of pyogenic infection in tonsils, teeth, etc., are subsidiary but important elements in a successful treatment.

Archives of Neurology and Psychiatry, Chicago

April 1, 1919, **1**, No. 4

*Disturbances of Spatial Orientation and Visual Attention, with Loss of Stereoscopic Vision. G. Holmes, London, England, and G. Horrax, Boston.—p. 385.
*Probable Etiologic Factor in Multiple Sclerosis. M. S. Woodbury, Clifton Springs, N. Y.—p. 408.

Personality Tests Involving Principle of Multiple Choice. A. Myerson, Boston.—p. 459.
Spinal Cord Injuries in Warfare; W. F. Schaller, San Francisco.—p. 471.

Disturbances of Spatial Orientation and Visual Attention.—The chief symptom in the case cited by Holmes and Horrax was inability to orientate accurately in space objects perceived by either central or extra-central vision, and especially to recognize the absolute relative distances of things seen, though by touch and sound he localized sensible objects as readily as normal persons. His power of distinguishing and comparing lengths and sizes was similarly affected. Stereoscopic vision was abolished; he was unable to see tridimensional objects in perspective and to recognize depth in anything. These symptoms disturbed the performance of various actions in which he relied on sight for guidance. He also presented a severe disturbance of visual attention, which made him unable to perceive readily or at all objects outside macular vision when his attention was held by that on which his eyes were fixed, and a failure to explore space spontaneously with his eyes; yet objects which threw even large images in his retina were generally perceived whole. Further, he was unable to evoke topographic memories acquired in the past and to learn his way in new surroundings. Finally, he had various anomalies of the ocular movements and reflexes, as failure to fixate promptly objects seen, to accommodate near objects, and to blink reflexly to threatening gestures. His visual fields were reduced by blindness of both lower quadrants, but the acuity of central vision was good.

Focal Infection Cause of Multiple Sclerosis.—The basis of Woodbury's paper rests on the observation of six cases of multiple sclerosis. All of the six were symptomatically typical. Two were relatively early, the others were more advanced. Spasticity of both legs and bilateral Babinski sign were present in all; abdominal reflexes were uniformly absent; all, except one early case, showed pallor of the temporal half of each disk; nystagmus and intention tremor were present in all. All had complained of bladder irritability which had appeared early in each instance; incoordination of upper as well as lower extremities was present in all. Sensory symptoms were practically absent. The only possible etiologic condition regionally common to all was some type of inflammatory disease of the upper respiratory tract. Every one of the six patients had obviously chronically infected tonsils which Woodbury thinks is worthy of note. This was the one pathologic feature in addition to the disease of the nervous system which was common to all, and the only one which seemed to give any definite inkling of etiology except that five of the patients had also—as dentograms revealed—peridental infection. This, however, was not strikingly extensive, either in the number of teeth involved or in the degree of involvement. No dental observations were made on the other case. Therefore, Woodbury offers the theory of a possible localized infective source, distributing its toxic products through the circulation, as a cause of multiple sclerosis. Four of these patients had their tonsils removed. Two relatively early cases report themselves as "well," despite the fact that both had previously been greatly hampered by motor incapacity and bladder trouble; one of these developed infected antrums after the extraction of periabscessed teeth, but reports a favorable convalescence. In one rather advanced case, four months after observation, the patient is walking without a cane for the first time in several years. In another advanced case, the patient walks with much greater ease, one and one-half years after observation; is less easily fatigued, and pursues his work in the lumber business daily. These four are all leading active, useful lives.

Study of Psychoses.—Seven cases which presented as the most prominent symptoms a more or less pronounced perplexity associated with distress are reported by Hoch and Kirby. They believe that these attacks represent a definite reaction type, because in spite of certain differences, the cases are remarkably uniform.

Changes Produced in Growing Bone After Injury to Epiphyseal Cartilage Plate. S. L. Haas, San Francisco.—p. 226.

Tendon Transplantation of Foot.—Of these forty-eight cases, cited by Steindler, thirty-six showed good result, or 75 per cent. The rest are divided into fair, poor, and undetermined on account of too recent operation. By eliminating all cases in which less than one year had elapsed between operation and time of writing, there remain twenty-four cases which have been observed one year after operation. Of these, seventeen cases, or 70 per cent., showed good result. By again eliminating all cases which are still in some kind of supporting contrivance, as cast or brace, we have at present thirteen cases, or 57 per cent., which have definitely shown good operative results. Of the four remaining in case it is to be expected that their present good result will be added to this number, making a definite percentage of good results, reaching the neighborhood of 70 per cent. for all cases. The technic of the operation done was described by Steindler in previous publications.

Six Hundred and Thirty-Eight Herniotomies. W. T. Dodge, Camp Sherman, Ohio.—p. 385.
Brief Résumé of Roentgen Ray Work in an Evacuation Hospital. I. H. Lockwood, M. C.—p. 389.

Treatment of Shell Shock.—In Frost's opinion the treatment of shell shock should be governed by the following rules: (1) It should be given only by medical officers specially trained in this work, one of whom should be stationed at each advanced aid station; (2) it should be instituted at the earliest possible moment; (3) it should be directed away from physical symptoms and toward psychic readjustment; (4) and most important, it must be carried on in constant conscious relation to the cause and mechanism of the condition as exemplified in the individual case.

Aero Ambulance.—Strong describes his design of aero ambulance in use at Eberts Field, Lonoke, Ark., for the transportation of patients. It has proved highly efficient and satisfactory. The ambulance is a remodeled Curtis biplane type J. N. 4 D, and it can be loaded in the same length of time ordinarily consumed in placing a single patient in the present type of automobile ambulance. Room is made for the patient in the rear cockpit. Emergency equipment is carried in a square canvas pack (similar to the present Hospital Corps pouch), with a strap so that it can be slung over the shoulder. The pack is suspended at the back of the front seat in the rear cockpit. A fire extinguisher and wrecking tools are also on board. When traveling to the scene of a wreck, the medical officer is seated in the rear cockpit and, being supported by a leather cushion, this permits him to be in a very comfortable position and enables him to act as an observer to assist in locating the wreck. The ship is well balanced, the load being distributed in the rear cockpit so near the normal load bearing points as not to make the ship tail-heavy, and requiring but few adjustments.

Cystoscopic Findings in Enuresis.—In this preliminary report by Pelzman which is based on an examination of sixty cases of enuresis, a new cystoscopic picture is reported. In the routine cystoscopic examinations at the base hospital at Camp Meade, Maryland, over a period of five months, forty cases of enuresis were encountered. The history in each of these cases was practically identical. The condition starts in infancy. There was always a history of at least one other member of the family affected by the same condition, and in several, more than one additional member of the family was so affected. The men were neurotic, and of an unstable type; almost without exception they would state that they were nervous. Cystoscopic examination disclosed no residual urine—the bladder was filled with from 300 to 400 c.c. of sterile water. A trabeculated bladder was found, trabeculation varying in degree from a mild to a very marked type. In most instances the floor of the bladder was involved, the trabeculations radiating outward and posteriorly from the ureteral orifices; in the more marked cases the entire bladder wall presented this picture. The findings were practically the same as those presented by the trabeculated bladders in tabetics. Very few of the cases showed any evidence of cystitis, although in several there were signs of a moderate degree of trigonitis.

Value of Psychologic Tests in Mental Cases.—Fearing is firmly of the opinion that an ideal situation is presented when a psychologist and a medical man collaborate on mental cases. This is especially true in the field of juvenile psychopathies and delinquents. Furthermore, that many of the puzzling cases which seem to involve some degree of nervous or mental inferiority and which present various contradictory subjective symptoms should not be diagnosed without reference to the scores resulting from properly conducted psychologic tests. A knowledge of such tests is not the only essential. They are only valuable when conducted by an examiner trained in the methods of laboratory psychology.

Lymphangioma of Chest of Child.—Philpot's patient was a little girl, aged 4 years. She was born with two small tumefactions—one below the axilla and one ju[illegible] above the clavicle to the left of the neck. The tumors g[illegible]ut little at first, [illegible] very rapid [illegible]th took pla[illegible]d constitutional [illegible] manifest[illegible] patient bec[illegible] weak and emaciated and at times having abnormally high temperature which was supposed to be due to some inflammation in the tumor. An incision was made in the tumor below the axilla, hoping to remove it, sac and all; but after draining the fluid out, it was found that the sac extended deep between the ribs and formed pockets all through the upper left chest, one of the deepest pockets extending to the scapula behind and another, between the clavicle and scapula, forming the large cyst to the left of the neck above. The sacs were adherent to the bones everywhere and all the sacs communicated; hence, drainage of all was accomplished. About a quart of blue fluid was drained off. After three curettings and swabbings a complete cure was effected.

Surgical Treatment of Goiter. M. F. Porter, Fort Wayne, Ind.—p. 431.

Are We Justified in Removing Healthy Gallbladders?—Cholecystectomy, in Magie's opinion, should be resorted to (1) in all cases of hydrops with stricture of the cystic duct; (2) in many cases of acute or threatened gangrene of the gallbladder; (3) in all cases complicated with embedded stones in the cystic duct with ulceration produced by contact with the embedded stone that when healed would probably cause the stricture; (4) in all very thick-walled gallbladders due to fibrous or calcareous degeneration; (5) in all cases of ulceration due to pressure of large stones; (6) in cancer of the gallbladder where the disease is limited to the gallbladder.

Parotitis as Postoperative Complication.—A trifle over one tenth of 1 per cent. of Collins' patients developed postoperative parotitis, and one died while waiting for operation. A study of these cases showed that postoperative parotitis is more apt to occur after abdominal operations than operations on any other part of the body. Its development is favored by a dry condition of the mouth and a lack of fluids in the body. The infection usually ascends through Stenson's duct. In patients whose abdominal condition makes it necessary to withhold food and drink from the mouth and stomach for a time, prophylactic treatment should be instituted. Collins advises that the mouth should be kept clean and moist by its own secretions and the body should be supplied abundantly with water. A good way to excite the secretions of the mouth and to keep a current of saliva flowing down Stenson's duct is to allow the patient to suck a stick of lemon candy after operation. A very accurate and effective way to supply the body with fluid is to administer salt solution by hypodermoclysis. If the prophylactic treatment fails and parotitis develops and the inflammation is increasing, or is no better by the third or fourth day, the gland should be uncovered by a free incision and punctured in several places with blunt forceps and the incision packed with wet sterile gauze as suggested by Blair.

Ununited Fracture of Patella and Olecranon.—In these cases Albee uses an inlay graft. For the patella cases the graft is H-shaped and is taken from the head of the tibia. For the olecranon a sliding graft is used.

*Occurrence of Morgan's Bacillus in Chronic Discharging Wounds. H. E. Whittingham.—p. 306.

Functional Paralysis of Diaphragm.—Attention has been directed recently to the rapid, shallow type of breathing occurring in late cases of gassing, and Haldane has associated the condition with an exaggeration of the Hering-Breuer reflex. The condition has also been observed in cases in which nervous symptoms have developed as the result of shell shock or other disturbances. The observations made by Watson and Meighan in two cases seem to indicate that a paresis or paralysis of the diaphragm, the result of functional disturbance of the center of the phrenic nerves, may account for the acceleration in breathing in some cases. Tracings taken from the two patients seemed to indicate a failure in the action of the diaphragm, and the authors suggest that it is probable that the acceleration in rate was due to this. They found that no discomfort was caused by breathing at 75 a minute, but when the rate was increased to about 170 a minute, it could not be maintained for any length of time. So long as it was maintained it showed no decrease in the abdominal movements.

Pneumothorax Paradox.—Coley calls attention to the fact that an artificial pneumothorax may relieve shortness of breath. The explanation he gives of this paradox is that the dyspnea in phthisis is not mainly mechanical and due to the amount of lung tissue which is disabled by structural disease: it is toxic. The artificial pneumothorax reduces the output of toxin.

Artificial Double Pneumothorax.—McCallum was not a little surprised to find a patient breathing quite comfortably and moving about with no embarrassment, although, in the routine treatment of a case of pulmonary tuberculosis by artificial pneumothorax he had produced a double pneumothorax of some considerable size through a patency existing between the right and left pleural spaces.

Morgan's Bacillus in Chronic Discharging Wounds.—Whittingham noted that certain deep wounds, which were moderately clean when first seen, gradually went from bad to worse in spite of careful treatment. These cases ultimately developed chronic discharging sinuses, the discharge having a peculiar odor very like that of a bacillary dysentery stool. Several of these patients were obviously suffering from a toxemia; blood cultures performed were negative. Cultures made from wound discharges of six of these cases revealed the presence in all of an organism identical with Morgan's No. I bacillus. This organism was the predominant one in most instances, but other organisms, such as streptococcus and staphylococcus, were numerous. Autogenous vaccines of Morgan's bacillus, given in two of these cases, greatly improved the wound and general toxic condition of the patient. In two cases there was a marked local and general reaction after the first inoculation, but when this passed off there was a distinct improvement in the condition of the patient.

Rickets. L. Findlay.—p. 147.

Hernia Across Lesser Sac of Peritoneum.—Four patients were operated on by Pringle on account of well-marked gastric symptoms, and in each of them it was found that practically the whole of the small bowel had herniated into and across the lesser sac of peritoneum. The only portion that had not been herniated was the last 6 to 8 inches of the ileum which formed the emerging coil of the bowel. In each of them the bowel had entered the lesser sac through that portion of the transverse mesocolon which is bounded by the vascular arch formed by the middle and left colic arteries, i. e., through that part of the mesocolon where it is usually divided when one makes a posterior gastro-enterostomy. In two of the patients the bowel escaped from the lesser sac into the general peritoneal cavity again through the gastrohepatic omentum, and in the other two through the gastrocolic ligament. Pringle has found records of only five other cases which seem to have any bearing on the subject, and of these, only two were operation findings.

Simple Apparatus for Isolating Single Organisms. R. H. Malone.—p. 222.

Rôle of "Reading" Bacillus in Wound Treatment.—The new method of treatment for gunshot wounds described by Donaldson depends on the utilization of a spore-bearing anaerobe of a saprophytic nature, a member of the proteolytic group of anaerobic organisms, which is probably present in the majority of gunshot wounds, but whose activities are generally held in abeyance by the system of wound dressing usually adopted. Donaldson has named it the Reading bacillus. It is highly resistant to heat and drying, and grows best in a slightly alkaline medium. It most closely resembles *B. sporogenes* (Metchnikoff). It is nonpathogenic for animals as well as for man when introduced into septic wounds. It does not attack living tissues. The use of salt is not necessary for the successful treatment of gunshot wounds, as was thought by those who advocated the salt-bag method. The success depends rather on the activity of this particular bacillus under conditions favorable to its growth and not on the salt. The rationale of the method depends not on inhibition by the Reading bacillus of the growth of pathogenic organisms in the wound either by reason of the formation by the bacillus of any inhibitory organic acid, or by the production of any bacteriolytic ferment. It acts, however, by virtue of its proteoclastic enzymes as an organic catalyst which hydrolyzes the substrate of dead protein. It distintegrates the protein base from which pathogenic organisms operate, and while so doing, does not itself give rise to fresh toxic substances. Not only so, but it is probably able to hydrolyze also the toxic degradation products of other organisms. In support of this theory a résumé is given of experiments on tetanus and other toxins, which show that the Reading bacillus, out of a series of organisms investigated, is alone able to reduce the toxicity of these toxins. There is one exception, namely, *B. sporogenes* (Metchnikoff), which, however, does not appear to be so potent in this direction as is the Reading bacillus. Donaldson suggests that this ability to modify a toxin like that of tetanus may prove to be of value as a means of differentiating various types of proteolytic organisms, while it introduces new ideas in regard to the biologic processes going on in septic gunshot wounds. Donaldson has termed his method the biologic method.

Studies on Streptococci in Relation to Wound Treatment.—The work done by Malone and Rhea was undertaken primarily with the hope that they might be able to assist the surgeon in forming an opinion with regard to the proper surgical procedure, subsequent treatment and prognosis in cases of streptococcal infection; for all of these depend in some degree on the particular type of infecting organism. Twenty-five of the cases studied were analyzed. In these the lesions chosen for special study bore an indirect connection with the track of the missile and with the outside or contained streptococci in pure, or nearly pure, culture. In direct injuries of the knee joint and indirect injuries with fracture of the femur or tibia, streptococci are usually found before the fifth day. In secondary infections, when there has been no fracture into the joint, streptococci are recovered from the knee-joint fluid from the eighth to the twentieth day. In thoracic injuries with infected hemothorax, these organisms are found between the seventh and fourteenth day after injury. Nonhemolytic streptococci are an uncommon cause of the surgical complication of wounds, except in cases of hemothorax, where they are usually of the types found normally in the respiratory tract. *Streptococcus pyogenes* is the type most commonly found in infected wounds. It is also the most pathogenic. The evidence to support the latter view is as follows: Of eight cases of infection in the knee joint, five developed secondary abscesses in the thigh or calf. *S. pyogenes* was found in the knee fluid and abscesses in each of these cases. Of three cases of infection in the knee joint which required amputation, two contained *S. pyogenes*. Four cases of infected hemothorax ended fatally; three of these were due to *S. pyogenes*. This organism was recovered from the three cases of infected open wounds of the soft tissues, which were complicated by an infected hematoma or abscess. There was only one serious case of infection in the knee joint that was not caused by *S. pyogenes*. There was only one mild case of an infected knee joint in which *S. pyogenes* was the causative agent, and this case had the advantage of very early surgical treatment. So far as streptococci are concerned in the surgical complications of wounds of war, the type which is most common, and leads to the most serious results, is the same as that encountered in civil surgery.

Picric-Brass Preparations in Treatment of Lupus.—The combination used by Ellis is formed by combining basic copper sulphate with basic zinc sulphate in the proportion of 86 per cent. basic copper to 14 per cent. basic zinc.

Hysterical Perpetuation of Symptoms.—Cases are cited by Rixon to illustrate the hysterical perpetuation of symptoms long after the original causes for them had disappeared. In a multiplicity of conditions this is liable to occur, especially in those which run a chronic course; nerve suture, neurolysis and capsulotomy of a traumatic neuroma especially are mentioned. Disordered gaits are perpetuated after fractures and injuries of the lower limbs; sciatica is also especially liable to produce this condition of affairs, and many other diseases with a chronic or semichronic course. Several factors help in suggesting the perpetuation of symptoms, as, for instance, the use of crutches and sticks. Many other things may be the means of suggesting a perpetuation of a disability, and in some cases it is due to autosuggestion.

Bacteriology of Influenza Cases.—*B. influenzae* was present in the sputum examined by Hicks and Gray by direct film in 70 per cent. of cases and by culture in 75 per cent. of cases. Pneumococcus was present in 100 per cent. Other organisms of the *M. catarrhalis* type were present, and mouth organisms. *B. influenzae* was present in nasopharyngeal swabs in 80 per cent. of cases. In pleural fluids they found a pleomorphic streptococcus having many characteristics of the pneumococcus, but often occurring in chains of great length. Some cultures showed hemolytic properties, others did not. The authors regard this as being of *S. mucocus* type. A leukopenia was usually present in severe or fatal cases. In the average pneumonic cases a moderate polymorphonuclear leukocytosis was present. Postmortem and histologic appearances showed the disease to be an acute capillary bronchitis and alveolitis.

Influenzal Intra-Abdominal Catastrophes.—Three points have been observed in the influenzal pseudo-abdominal catastrophe which differ from the true surgical abdominal lesion. (*a*) The movement of the alae nasi. In cases of influenza with acute abdominal pain, even when no physical signs have appeared in the lungs and the respirations are only slightly increased, if the alae nasi are working, the condition is never abdominal. It occurs only in late true abdominal lesions when general peritonitis is well advanced. The movement of the alae nasi may not be very marked when the patient is recumbent, but can be elicited with a little exertion. (*b*) Dulness in the flanks is never present in influenzal pseudocatastrophes except in Class A, in which it is an early sign. (*c*) The facies of the influenzal victim dominates the scene. The anxious terror-stricken look of the true abdominal lesion is not present, as a rule. The anxiety is more lethargic and resigned, and of the medical rather than the surgical type. Smith emphasizes that in some cases an unusually high temperature associated with acute abdominal pain should be regarded with suspicion by the surgeon.

*Fate of Starch Granules Injected into Rabbit's Vein and Tissue. M. Okazaki.—p. 1.

Fate of Starch Granules Injected into Rabbit's Vein and Tissue.—For the purpose of examining whether the starch granules introduced into the rabbit's vein are converted into the substance showing glycogen reaction, 5 c.c. of the prepared starch emulsion (a 0.5 c.c. of sweet potato starch suspended in 20 c.c. common salt solution) was injected daily into the ear vein of a rabbit. Okazaki found that the introduced starch granules were, in most part, retained in the pulmonary capillaries, and not conveyed into other organs by circulation, owing to the larger granules themselves. In two rabbits which were killed on the day of the third and fifth injection, the starch granules in the pulmonary capillaries did not present any chemical reaction for the glycogen substance. In other rabbits which were killed on the sixth day and some after seven days, the positive reactions were demonstrated; the longer rabbits lived the more obvious change noticed. In these cases, it was interesting to note that the majority of the converted granules were enclosed in newly formed giant cells which consisted of the proliferated capillary endothelium. The granules simply suspended in the blood stream presented a *less intense reaction*. In order to examine the change of the granules in the liver the same emulsion was injected directly into the vena mesenterica by performing laparotomy. The introduced granules were chiefly distributed in the periphery of the acini. As in the lung, the granules surrounded by the proliferical Kupffer's cells and the smaller granules were phagocyted by them. The intensity of the reaction was, also, more marked in such an enclosed granule. From the preceding facts Okazaki concludes that the endothelium of the lung capillary and the Kupffer's cell of the liver capillary show a diastatic action converting the starch into the glycogen reaction substance.

Dilatation of Stomach from Lack of Sufficient Resting Periods.—Hayem calls the type he describes *dilatation par trouble évolutif*, the evacuation being unduly prolonged and lapping over into the period of digestion of the next meal. Contrary to the German method of estimating the progress of the digestion by analysis of the stomach contents one hour after a test meal, Hayem estimates it by ascertaining the course of digestion, the *évolution digestive*. When the course of digestion is abnormal, it may take a very short time or a very long time to be completed. Some stomachs pass the food along at once, the stomach emptying itself in from ten minutes to an hour, but an abnormally protracted course of the digestion is a more common occurrence. The stomach does not empty itself completely between meals, so it never gets a chance to rest, and it is liable to become dilated from this overwork. There is usually with this *dilatation par trouble évolutif* a tendency to hypersecretion and hyperchlorhydria. Treatment with alkaline-saline waters generally corrects the condition provided the stomach is allowed a chance to rest. This can be realized by making the intervals between meals longer, and by reclining an hour before the meal, with a cushion under the seat, to give the stomach a chance to empty itself completely under the influence of gravity. The general rule is to lie down *after* eating, but to combat this form of dilatation the reclining is done *before* eating. Light massage of the stomach while reclining may prove useful in addition. He allows only two meals a day, at 10 a. m. and 7 p. m., or at 11 a. m. and 8 p. m. This gives an interval of nine hours between breakfast and dinner, and by this means the stomach is sure to be empty by mealtime. The patient may lose a little in weight at first, but gradually the whole condition improves; the stomach returns to its normal size and the former weight is soon regained and surpassed. If there is excessive or deficient secretion of gastric juice, the proper alkaline-saline mineral waters should be given as indicated, and if there is ptosis, a supporting belt may prove useful.

The Wassermann Reaction in Atrophy from Inherited Syphilis.—Barbier relates that in ninety-three infants with marked atrophy a positive Wassermann reaction was obtained in 33 per cent. and others presented signs of syphilis so that fully 42 per cent. were unmistakably syphilitic, and a number of others probably had the inherited taint likewise. But tuberculosis and alcoholism must be incriminated in others. Atrophy of alimentary origin is spontaneously and rapidly curable when the diet is corrected, but atrophy from a congenital taint is quite another thing. It may develop with the best of breast feeding and treatment has to be tentative, and it takes great patience. When inherited syphilis is involved, specific treatment may transform the infant, but mercury should be given extremely cautiously and in minute doses. Some infants with atrophy improve wonderfully under mercury, while others show no gain or the symptoms may even become aggravated under it, the children being unable to bear the slightest therapeutic intoxication.

Filariasis.—In the first of Panayotatou's two cases the filariasis was located in one labium and in the other case in the glands in the inguinal region. Severe local pain and great tumefaction were explained by discovery of the filaria in the blood. No treatment has proved effectual: prophylaxis consists in avoiding being bitten by mosquitoes and drinking contaminated water.

Mirror Writing.—Summarized recently, page 527.

Latent Tuberculous Peritonitis.—Joltrain and Baufle have had charge of a special service for gastrointestinal disease, and they have encountered a number of cases of unmistakable intestinal disturbances for which none of the usual causes seemed to be responsible. The general impression was that of incipient tuberculosis, but the lung findings were practically negative and vague digestive disturbances called attention to the abdomen. Radioscopy revealed always an enlargement of the ileum with constricted segments below and possibly at other points. This stenosis comes and goes, but the parts involved are more or less immovable from adhesions, evidently relics of an old infectious process. These adhesions generally spread like a fan; this can be palpated, and the palpation findings were confirmed at necropsy in two cases. The whole trouble is insidious and readily misinterpreted. If latent tuberculous peritonitis were sought for as a routine measure the same as pleurisy, it probably would be found equally frequently. Possibly this may be the explanation of dysmenorrhea in certain cases or of the disturbances for which the appendix may be incriminated in young girls.

Wounds of Posterior Urethra.—Marion reviews the management of the case after it reaches the hospital in the home territory. Pasteau discusses the measures to be applied from the very first to the last, both in the zone of activity, the zone of communications, and the home territory. These communications were presented at the fourth meeting of the chiefs of the *centres d'urologie*, and the discussions which followed are given also.

Illumination of the Bladder.—Uteau and Schwab expatiate on the advantages of using the cystoscope as an aid in throwing light into the depths of the well formed by the suprapubic incision of the bladder. The cystoscope introduced by the natural route illuminates the depths of the bladder most instructively, without encroaching on the field of operation.

*War Wounds of Maxillary Sinus. Vandenbossche.—p. 654.

Strangulated Diaphragmatic Hernia After War Wound of Chest.—In the case described with illustrations by Bérard and Dunet the sixth rib had been fractured. Some splinter of the bone had evidently irritated the diaphragm, and the constant movement of the latter increased the irritation with gradual laceration and, by the end of the fourth month, hernia through the breach thus formed, and the hernia became strangulated. There were no symptoms from the heart and lungs, no meteorism, and only pain around the umbilicus, arrest of passage of feces and gases, vomiting and almost absolute gastric intolerance. Some digestive poisoning was assumed at first, and even up to the fourth day on account of the absence of intestinal symptoms with the ileus. Before the strangulation, the only symptoms had been a painful tension, felt near the thorax, accompanied by gurgling sounds, most pronounced after meals and in the reclining position. Even fluids were vomited almost at once, but it is possible that during the briefly transient period before the stomach expelled the fluid, auscultation might have given the clue. The right-angled incision gave access to both thorax and abdomen. Three fourths of the stomach and 42 cm. of the transverse colon had slipped through the breach. No tendency to gangrene was found at necropsy, but there were numerous solid intrapleural adhesions between omentum and pleura.

Wounds of the Brain.—Weissenbach and Audibert warn that the presence of some foreign body is indicated when there are recurring aseptic puriform meningeal reactions. In a case described this recurring reaction occurred in the course of a suppurative ventricular ependymitis consecutive to a scrap of shell having penetrated the brain. The symptoms from the meningeal reaction subside but as the underlying cause persists, the reactions develop anew. The prognosis is thus grave unless the primal cause is sought and removed.

Albert advocates primary suture after wounds of the skull and brain and reports twenty-nine cases to illustrate the advantages of suturing the dura at once without draining. After the wound has been thoroughly cleared out, the danger of infection is always from without. Hence, by prompt suture of the dura and of the scalp, this danger is averted. Drainage should be reserved for the entirely exceptional cases, and tamponing of the wound should never be done. He describes in turn the different classes of wounds, and states that in his twenty-nine cases the immediate results were excellent in all but two cases in which the dura had been torn so much that the suture could not be realized. Even if it is known that there is an inaccessible splinter in the depths of the wound, he insists that primary suture is still the best procedure, ensuring healing by primary intention.

Thrombophlebitis of Cranial Sinuses.—Bellin and Aloin report a case of this kind originating in a carbuncle at the back of the neck in an Arab soldier. Tetaniform convulsions and facial paralysis were accompanied by the Gradenigo syndrome, paralysis of the fourth to the seventh nerves, and necropsy revealed abscesses and thrombosis through the whole venous system of the dura mater and brain.

Oculomotor Paralysis After Fracture of Petrous Bone.—Mardellis' patient was injured handling a log. The fracture of the apex of the petrous bone was followed by unilateral and isolated external oculomotor paralysis, paralytic convergent strabismus, with complete recovery in six months.

War Wounds of Maxillary Sinus.—Vandenbossche analyzes his experience with sixteen cases of this kind. They demonstrate the fine results that can be realized with collaboration of specialists in rhinolaryngology and plastic facial surgery.

Tuberculous Soldiers.—Gaussel was appointed in 1914 to reexamine the men who had been discharged from military service on account of tuberculosis during the twenty-seven years preceding the war. Recently he reinvestigated the present status of those whom he had passed in 1914 as having recovered sufficiently to be capable of military duty in some form. Of the total 496, 172 were found unfit for service; 202 had apparently completely recovered and were passed for active service, and 122 had been passed for light duty only, the auxiliary service. Of a total of 310 accepted, 246 were still in the service at the close of the war, including 135 in active service. Classifying them by ages shows that the larger proportion of the permanently cured were among the men between 25 and 35.

Treatment of Chronic Alcoholism. E. Koechlin.—p. 277.

The Heart in Influenza.—Eichhorst states that he found anatomic evidence of injury of the heart from the influenza in only 0.3 per cent. of his 2,411 cases, but functional disturbances were extremely common and characteristic. They assumed the form of tachycardia or bradycardia, extra systoles or cardiac neuralgia but were never severe enough to endanger life. He describes examples of each type and calls attention in particular to the case of a physician who was suddenly surprised with intense tachycardia in the midst of apparent health. The heart beat was 200 with a pulse of only 148. Eichhorst advised him to go to bed or lie down, eat only fluid food, avoid tea and coffee, and he prescribed a sedative and heart tonic. The sixth night the tachycardia subsided during sleep; on waking the heart beat was only 84. The heart irregularity had been ascribed to abuse of coffee and tobacco but as the tachycardia subsided, symptoms of afebrile influenza became apparent and persisted for a week. Bradycardia was more frequent; cardiac neuralgia was encountered only in three cases. In all these influenza heart cases the patients were men; possibly, Eichhorst remarks, alcohol and tobacco may have contributed to the functional disturbance.

Intrameningeal Hemorrhages in the Newly Born.—Vischer analyzes what has been written on laceration of the tentorium during delivery, and reports the findings in this respect in 186 fetuses and newly born children. In 112 of the cadavers nothing visibly pathologic was found in brain or meninges. In 51 of the other 74 the tentorium had been torn, with considerable hemorrhage resulting in 27. In 24 there was no or only slight hemorrhage. In 23 there was hemorrhage but the tentorium was apparently intact. Laceration of the tentorium thus had occurred in 27.3 per cent. of the 186 cases. The birth process had been apparently normal in some and no regular connection with the mode of delivery could be detected. The cadaver of one adult male showed laceration of the tentorium after lateral contusion of the head as the man was looking out of a car window while passing a wall that stood close to the track. Vischer agrees with Beneke that laceration of the tentorium in itself should not be cited as the cause of death. The resulting hemorrhage is the danger. The intrameningeal and other hemorrhages are probably synchronous. He remarks in conclusion that the birth process injures the skull contents more than has hitherto been realized. This assumption is confirmed not only by the findings here analyzed but also by Paul's ophthalmoscopic findings in the newly born.

Absorption with Sugar Treatment of Tuberculosis.—Bodmer reports the results of research on the absorption processes after intramuscular injections of 50 per cent. sugar solution by the Lo Monaco technic. He has thus treated fourteen patients, making a total of 500 injections. He was surprised to find that all the injected saccharose was eliminated through the kidneys, and all in the course of forty-eight hours. The maximum of the elimination was reached in from four to seven hours. The sugar was eliminated without being inverted, and hence cannot have any causal therapeutic action, but the symptomatic effect of reduction of exudation and irritation was pronounced, with striking reduction in the amount of sputum. This action was most evident in the comparatively recent cases. He has never seen such a pronounced effect from any drug, and the only explanation can be the modification of the osmosis and, possibly, a vasomotor influence. Other sugars should be given a trial, and this treatment be extended to chronic bronchitis, etc.

*Staphylococcemia Simulating Typhoid with Relapses. U. Baccarani.—p. 89.

Staphylococcemia Suggesting Typhoid.—Baccarani insists that the staphylococcus does not always induce suppuration. It may produce a set of symptoms closely resembling those of typhoid, and it may return two or three times with intervening periods of latency, as if the disease was typhoid with one or more relapses. In one typical case a girl of 8 had apparently recovered from a small ulcerative lesion on the gum, but three weeks later came a chill and fever, the latter persisting for nearly two weeks and then it subsided completely. The child's aspect, lack of appetite and diarrhea led to the assumption of typhoid, until the fever subsided completely. After a few days of apyrexia, the temperature ran up again, with meteorism, diarrhea and an area of dulness. This attack lasted for a little more than two weeks, and again it subsided. After an interval of a few days the temperature ran up again for a third attack, and typhoid was then regarded as certain and the child was sent to the hospital, forty-two days after the initial chill. The tests for typhoid were negative, while staphylococci were cultivated from the blood. Each one of the attacks had produced the clinical picture of typhoid in every particular, he says, but the fourth and last attack—which occurred while in the hospital—was followed by an abortive osteomyelitic process in the tibia which retrogressed without suppuration, and the child left the hospital apparently cured, after a three months' stay. In the intervals between the pseudo-typhoid attacks, she felt well and ate with appetite. In a second case the onset and course were those typical of typhoid, and the woman was being treated for typhoid in the hospital when, three weeks after the first symptoms, the fever subsided by lysis and the other symptoms disappeared, the spleen returning to normal size. Four days of apyrexia followed; then the "typhoid" returned and the liver became much enlarged but without any special tender point. This second attack lasted for two weeks and then apparently complete recovery followed, by the end of the fourth month.

Baccarani has encountered a number of such cases but reports in detail only three, calling attention in particular to the extreme enlargement of the liver during the febrile attacks and its prompt subsidence to normal size during the afebrile intervals. The clinical picture of typhoid was complete even to the rose spots in some of the cases. De Rossi has recently reported that in four cases of supposed typhoid, confirmed by necropsy findings, no typhoid bacilli were found, but the *Staphylococcus pyogenes-albus* was cultivated from the spleen. Further testimony incriminating the staphylococcus comes from Pisa and Bologna, where Bonardi and Bruschettini noted epidemics of staphylococcus sepsis simulating typhoid fever. Staphylococcus sepsis, however, does not always induce this typhoidal state. There may be very high fever, but the patients feel well and eat with appetite. This lack of harmony between the fever and the general condition may serve as a clue to staphylococcus infection. Transient congestion in lungs and pleura is sometimes encountered during an attack, with the pneumococcus in the sputum. The patients complain at times of pains at the epiphyseal line of various bones, but there are no objective findings. In none of his cases was anything found to indicate suppuration at any point, although some spots of slight and transient redness, pain and swelling occurred at times in the skin, suggesting an impending furuncle, but always promptly retrogressing without leaving a trace.

Spread of Tuberculosis. T. Rossi-Doria.—p. 237.
Advantages of the Pécharmant Apparatus for Fractures. U. Daretti.—p. 240.

The Anamnesis.—Mingazzini expatiates on the importance of what he calls the catamnesis, that is, the eliciting from the patient the preceding history of the case. The way this is done shows the master physician. It is equally difficult when the patients are great talkers and when they are taciturn, but the main difficulty is a lack of attention to important details while the unimportant are exaggerated. He outlines a general scheme for interrogating the patient after letting him tell his story in his own way, if not too prolix. He adds that few are aware how many nervous symptoms labeled with the convenient diagnosis of neurasthenia are in reality the result of abuse of tobacco. The patient will seldom mention that he has been advised by other physicians to give up tobacco. One of the most common errors in diagnosis is when a new morbid process develops with the same symptoms as an older process, as for example when a person subject to migraine in youth develops cerebral pachymeningitis. The new symptoms seem to be merely the same old migraine. Persons with sexual neurasthenia can often be recognized by their pale and timid aspect alone. Nephritis and diabetes may at first manifest themselves by nervous symptoms alone, and only examination of the urine will give the clue to the cause of the pains and other nervous symptoms. Much time is wasted on inconsequent details in case reports read in the classes. The students pay no attention to the account of the eruptive diseases in childhood, date of menstruation, trauma, heredity, etc., and time is wasted in their enumeration. This does not fix in the minds of the hearers the fundamental points in the antecedents; these can and should be reduced to a minimal common multiple. "In short," he concludes, "may it be said of us what was said of a scientist over a century ago with some surprise: *Il était un savant et pourtant pas bête.*"

Quinin by the Vein.—Nicotra insists that quinin injected intramuscularly does not reach the blood in time to act on the malarial parasites at the most favorable moment or with the most effectual concentration. It reaches the blood only a little at a time. On the other hand, when injected into a vein it reaches and acts on the parasites at exactly the desired moment and in the maximum strength. He urges therefore to begin with intravenous injection of the maximal dose at the very first attack when the patient comes for treatment. In the majority of his hundred cases thus treated, one injection proved sufficient; rarely, two were necessary and, only quite exceptionally, three. There was one recurrence among the eleven cases of estivo-autumnal tertian and five recurrences among nine cases with irregularly long intervals. None of the others have had any attacks since the intravenous treatment. He declares that we can count on curing all primary cases by intravenous injection of 1 gm. of quinin during the febrile attack and also cases of recurrence with short intervals. When the injection is made while the fever is rising, he could not see any difference in the course of the attack from the similar attacks without quinin. The latter never aborts the attack in question. During the declining phase of the fever the young parasites have worked their way into the red corpuscles. With the estivo-autumnal form he injects a little more of the quinin, up to 1.25 gm.

November, 1918, **8**, No. 11

*Diagnosis of Incipient Leprosy. M. Mourão.—p. 677.
Deficiency Diseases. G. Riedel.—p. 693.
Juvenile Paretic Dementia. W. De Almeida.—p. 706.

Incipient Leprosy.—Mourão describes with illustrations what he calls a new sign of leprosy. It is the result of the wasting away of the muscles on the ulnar side of the hand so that the edge of the hand is thin, forming a sharp edge. The muscles controlling the little finger and the hypothenar region become atrophied and the palm smoothes out on that side. The muscles on the thumb side are not affected; the thenar eminence stands out more prominently from the contrast. The muscles of the inner aspect of the foot on the same side show similar atrophy, and there is loss of all sensibility, although the outer half of the foot and leg persist normal. He has observed these findings as the only manifestations of leprosy at first in some cases, the presumptive diagnosis confirmed later by the course of the disease. Among the other early signs he notes the extreme pallor in the nervous form of leprosy, while in the cases which develop the tubercular form later, the face becomes uniformly redder, not a bright red, but a little deeper red than normal. The veins are prominent, the skin looks smooth and shiny and is extremely sensitive, and any rubbing induces an actual erythematous redness. The loss of sensibility occurs in asymmetrical regions in a characteristic manner, affecting the ulnar side of the hand and the opposite side of the forearm up to the elbow; in the foot the inner aspect of the foot and the outer aspect of the leg—all on the same side of the body. A sensation of cold, even on warm days, is an early symptom of leprosy. Some lepers complain of hot flashes like those of the menopause, along with intense and continuous chilliness. He advises to be on the lookout for leprosy all the time, even when it seems preposterous to suspect it, and relates a number of cases in which treatment had been given for everything but the correct diagnosis. Mourão knows of a priest, a physician and a midwife, who have not allowed the fact that they have leprosy to interfere with the practice of their professions, and he has noted leprosy in barbers, servants and others. He mentions further a specific case of unacknowledged leprosy in a prostitute and one in a public school teacher, and refers to dozens of similar cases. One young man had been treated for progressive muscular atrophy and rheumatism for two years without benefit until his confession that his father had advanced leprosy cleared up the maze of symptoms. Mourão found that chaulmoogra oil arrested the disease as a rule, but this is a two-edged sword as it induces severe digestive disturbance. In conclusion he describes the Hospital dos Lazaros at Rio with its large gardens, music rooms, cinemas, orchestra, library and work rooms, as the solution of the national leprosy problem. This prevents contagion of others; it is a leper asylum from which no one wants to escape, a prison without bars, but its capacity is limited. Similar establishments scattered throughout the country would settle the question of prophylaxis.

Archivos Españoles de Pediatria, Madrid

December, 1918, 2, No. 14

Influenza in Children. C. S. de los Terreros.—p. 705. Conc'n.
*Environment in Neuroses in Children. C. Juarros.—p. 719.
Malformation of Urinary Apparatus. F. Iruegas.—p. 724.

The Environment in Neuroses in Children.—Juarros protests against the usual disregard of the conditions in the environment when a child presents a nervous tendency. A change to another environment will often cure a severe neurosis, or the removal of some one person from contact with the child will sometimes prove the key to the problem. In one of two cases reported a girl of 8 had been having three or four convulsions a week for a year, evidently of hysteric origin. Doctor after doctor was consulted and all diagnosed hysteria and ordered sedatives and general hygiene. When the child was brought to Juarros, he investigated conditions in the home and thus found that a cousin who lived in the family was subject to hysteria and convulsions. As this woman was a fixture in the family, the child had to be sent away from this mental contagion. She was placed with other relatives, and after the first month had no more convulsions during the following five months to date. In the other case the girl of 7 was unusually bright in school and her parents were "showing her off" constantly to friends, and taking her to shows, etc., so she did not get to bed till 12 or 1 and she had no rest during the day. Restless, agitated, light broken sleep, talking in her sleep, her condition resembled that of maniacal excitement in adults. The general health suffered, the appetite was lost, and she was growing thin when Juarros was consulted. He convinced the parents of the evils of their management of the child, and when this was corrected all disturbances speedily subsided. Every one admits theoretically that the seed for neuroses in adults is generally sown in childhood, but in the specific case this is too often forgotten.

*Differentiation of Filaria in Blood and Feces. H. de B. Aragão.—p. 1.
*Syphilis and Obstetrics. F. Magalhães.—p. 2.

Differentiation of Filaria and Helminths.—Aragão calls attention to a modification of Thoma's solution which colors most of the parasites in stools and blood and preserves them, while dissolving out the red corpuscles. The formula is: gentian violet, 0.1 gm.; sodium chlorid, 0.35 gm.; distilled water, 100 gm., and acetic acid, 0.3 gm. About 0.5 c.c. of the blood is added to 5 c.c. of this solution. In examining for filaria, use 2 c.c. of the solution for 0.5 c.c. of feces. Both amebas and their cysts show up well by this means and keep perfectly for many days, the cysts for several months; also lamblias, blastocytes, bacteria and the ova and the larvae of helminths all show up well in this acetic solution of gentian violet.

Syphilis and Obstetrics.—Magalhães reviews the six principal ways in which syphilis influences pregnancy, from the prevention of conception to interference with delivery. Syphilis may be incriminated for certain cases of sudden deaths during delivery which otherwise seem inexplicable. The suprarenals have been so damaged by the syphilis that the woman's system is unable to bear the strain of parturition, or, if the cerebral vessels have been damaged as well, the toxic hypertension in this case produces a terminal hemorrhage in an eclamptic convulsion.

*The Arrhythmias in Prophylaxis and Treatment of Heart Disease. G. N. Martinez.—p. 217.
Clamps etc. for Surgical Work. E. Finochietto.—p. 220. Cont'n.
Echinococcus Cyst Simulating Peritonitis. J. P. Garrahan.—p. 221.
*Hexamethylenamin in Typhoid. L. Ymaz and L. Ayerza.—p. 224. Conc'n.

Arrhythmia as Guide to Treatment of Heart Disease.—Martinez declares that his observation of cases of heart disease has convinced him that arrhythmia is always a sign of pathologic reduction of the functional capacity of the heart, the result of actual intracardiac lesions of some kind. He insists that the nervous system alone is unable to modify the rhythm if the heart is absolutely histologically and functionally sound. He has found that the cadaver always revealed more or less pathologic conditions in the heart in every case of arrhythmia that came to necropsy. He adds that sinusal arrhythmias and the simple so-called reflex extrasystole are a warning signal of heart disease that should never be disregarded. The Wassermann reaction has demonstrated the syphilitic factor in most of the arrhythmias in childhood as well as in adults; rheumatism and smallpox contribute another percentage, as also tuberculosis and derangement in the endocrine glands. The products of brain fatigue, such as accumulate in consequence of insomnia and other intoxications, make their deleterious influence felt on the heart. Prophylaxis requires hygiene and avoidance of irritation from the toxic action of unsuitable food and drinks and other causes, and complete moral and material repose for the nervous system. He advises to tranquillize the patient, repudiating all ideas of a grave condition, soothing the nervous system, investigating the glands with an internal secretion, and diverting the patient's attention from his heart. It behooves the physician to discover the incipient evil, and it behooves the patient to ignore it until hygiene, dietetics, drugs and suggestion from the physician have convinced him of the immense reserve power with which the heart is endowed. Then the mystery of his heart disease can be revealed to him.

Hexamethylenamin in Typhoid.—Ymaz and Ayerza here conclude their experimental study of the physiologic isotonicity of solutions of this drug and of its intravenous administration in typhoid and its elimination.

*Vertebral Sign of Syphilis. M. R. Castex.—p. 232.
*Albumin in Cerebrospinal Fluid. A. Prunell.—p. 232.

The Leukocytes in Immunization.—Reviewed April 5, p. 1041, when published elsewhere.

Sign of Tardy Inherited Syphilis.—Castex emphasizes the diagnostic importance of bifurcation of the spinous process of the first lumbar vertebra as a frequent sign of inherited syphilis. One or more vertebrae may be involved; in one case the bifurcation was in the twelfth dorsal vertebra. He remarks that there are no anatomic or embryologic reasons for this bifurcation, and it must be regarded as pathologic. To date he has found it only with inherited syphilis.

Quantitative Test for Albumin in Cerebrospinal Fluid.—Prunell prepared a set of seven test tubes containing from 0.7 to 7 parts cerebrospinal fluid known to have an albumin content of 1.40 gm. per liter. Enough physiologic serum is added to each tube to make ten parts, namely from 9.3 to 3 parts. Each test tube contains 2 c.c. of the mixture, and to this are added 10 drops of a 25 per cent. solution of trichloracetic acid; the tube is fused, heated to 100 C. and then to 110 C. for ten minutes. The tubes are then placed in a frame against a black background. The fluid to be examined is treated in the same way and then it is placed beside one of the standard tubes while a printed card is slipped behind both. The tube which allows the letters on the card to be read with the same facility through both tubes serves as the index for the albumin content. Ten different fluids were tested by this diaphanometric method and also by the gravimetric, the gasometric and chronometric procedures, and the comparative findings were found approximately the same. Two illustrations accompany the article.

Anatomy of Pterygoid Process. J. J. Cirio.—p. 27.
*Indirect Operative Treatment of Gastric Ulcer. C. Alvarez (Oviedo, Spain).—p. 30.

Indirect Operative Treatment of Gastric Ulcer.—Alvarez operated on account of an ulcerated lipoma straddling the upper spine. The woman of 40 had had stomach symptoms and hemorrhages typical of gastric ulcer for thirty-eight months. Two days after excision of the tumor in the back the stomach symptoms subsided completely and permanently with no return during the eight years later until the woman died of phthisis. This remarkable indirect cure of the gastric ulcer confirmed the nervous origin of the latter, and suggested that a similar lesion artificially induced might cure gastric ulcer in other cases. Since then Alvarez has attacked this same group of nerves as in the first case, namely, the sixth, seventh, eighth and ninth pairs, reaching them through a bilateral incision about 8 cm. long, cutting down to the bone, from the sixth to the tenth rib, three fingerbreadths from the median line. The lips of the wound are kept apart by retractors held by an assistant. Then each intercostal space is incised perpendicularly to the ribs, cutting through the muscle. The edges of this muscle are drawn apart and with the bistoury the deep fascia is cut parallel to the rib. Through this 5 mm. opening, the intercostal nerve is drawn up with a hook and seized with Kocher forceps, with care not to rupture any vessels accompanying the nerve, or to induce pneumothorax. The nerve is then severed and the central stump is well stretched, concluding with torsion. Experiments on the cadaver have shown that the effect on the nerve is stronger from the stretching than from the torsion. He gives the details of a number of cases of different types of disturbances, ulcer, hyperchlorhydria, hypersecretion and spasmodic stenosis, even ectasia of the stomach, all showing prompt and permanent benefit from this indirect treatment of gastric ulcer by *conmoción a distancia del gran simpático,* as he calls it. It has little if any effect on disturbances from organic stenosis; these cases call for a gastro-enterostomy. The benefit from this indirect operation confirms the assumption that nervous influences induce the disturbance in the stomach; they shut off the blood supply at some point which permits autodigestion at this point, and also prevents normal repair. By severing the nerve connection, the circulation returns to normal as the stretching of the nerve tears the rami communicantes and breaks up their nerve connection with the stomach. Notwithstanding the persistence of the hyperchlorhydria, the ulcer does not return, and in time the stomach outline approaches normal once more. The operation amounts to a physiologic pylorectomy as it removes the causes maintaining spastic closure of the pylorus.

Smallpox at Barcelona. F. P. Freixa.—p. 69.

Puerperal Embolism.—Luengo reports the case of a woman of 40 taken suddenly with intense dyspnea, high fever and acute pain in the back and side of the right side of the chest, but there was no cough, no expectoration and none of the physical findings of pneumonia. She had given birth to her third child three weeks before. The puerperium had been normal, the woman getting up in five days, but inquiry elicited that she had been feeling a dull pain in the region of the left adnexa. The assumption of pulmonary embolism from a puerperal thrombophlebitis was confirmed by the persistence of the pulmonary symptoms for eleven days, when the fever subsided and a persisting cough developed with blackish bloody expectoration. After a week, phlegmasia alba developed in the femoral vein region and, eight weeks later, in the leg on the other side. These gradually subsided but by the end of the sixth week there was a new attack of embolism in the lung which ran a similar course. To ward off further embolism, the woman lay still in bed for three months and recovery then seemed complete. Treatment had been with revulsions, sedatives, quinin and serotherapy, ichthyol in the vagina and antistreptococcus serum. The general condition kept good throughout, the blood findings within normal range. The embolus causing the lung trouble must have been aseptic or very slightly septic.

Influenza in the Pregnant. J. A. Van Dongen. — p. 257.
Paralysis with Infectious Sore Throat. J. E. Schulte.—p. 264.

Bullet Wound of Heart Without Opening Pericardium.—In de Jong's case necropsy revealed that a prompt operation might have saved the young woman. The bullet had bored into the outer layer of the pericardium but the inner layer had stretched without rupturing. The impact was such that the distended ventricle was ruptured by the bullet, still driving the inner layer of the pericardium before it. There was thus a hole into the ventricle although the inner aspect of the pericardium was smooth and free from lesions throughout. He has found sixteen similar cases on record of gunshot wounds of the heart, without perforation of the pericardium, some with recovery.

*Diagnosis and Treatment of Kidney Stones. T. Rovsing.—p. 1.
Influenza in 1918. O. Thomsen.—p. 24.

Kidney Stones.—Rovsing here epitomizes his twenty-five years' experience in the diagnosis and treatment of kidney stones, a total of 533 cases, including 185 with blood borne infection and 221 in which the operation revealed aseptic conditions, with 127 aseptic cases in which no operation was attempted. In the majority of the surgical cases the kidney stone caused no symptoms until suddenly pains with hematuria or pyuria attracted attention; this may occur at any time in life from early childhood to advanced age. When a stone of this kind has been removed, the kidney shows no tendency to form other concretions. A transient fever, or a course of one-sided diet, may be the occasion for production of urates in such amounts as to entail a kidney stone. As an example of this he mentions the Swedish surgeon Lennander who developed a kidney stone apparently as the consequence of a course of "dry diet" taken at Nauheim on account of heart disease. On the other hand, it is extremely rare for the congenital uric acid diathesis to entail kidney stones calling for surgical intervention. The gravel and small stones are passed without need for an operation. Pains and hematuria in these cases are generally traceable to uratic nephritis or perinephritis for which nephrolysis seems to be the best treatment. One man has ten or twelve attacks each year of left ureter colic and passes gravel and stones no bigger than a pea, but radiography has never shown any considerable stone in the kidney. The right kidney persists normal.

Phosphaturia is frequently accompanied by large concretions; in four cases in which the tuberculous kidney had been removed, anuria developed later and he found the pelvis filled with large and small phosphate stones, one of which had become impacted in the ureter. The majority of cases of phosphate stones in the kidney are due to accidental or artificial phosphaturia. Frequently this is the result of a therapeutic course of alkaline mineral waters, possibly given to combat nephrolithiasis, regardless of the law that when a foreign body is laved in a solution of a salt, the foreign body becomes incrusted with the salt, even when the urine is limpid and sterile. Instead of dissolving the concretion, alkaline mineral waters add to its size by deposits of salts. Long treatment of rachitis with calcium salts may also lead to stone production in the kidneys.

Rovsing has encountered only two cases of cystin stones and both patients were permanently cured by removal of the stones and restriction afterward to distilled water. One was a woman of 32, the other a girl of 4. Both had had symptoms of cystinuria since early childhood, the woman's attacks of pain returning finally as often as every two weeks, always on the left side, and not spreading. During the five years since the nephrotomy the urine has kept free from cystin.

In some cases the disturbances from the supposed kidney stone proved to be due to the binding of the kidney in the fibrous degenerated true capsule; slitting this capsule and releasing the kidney cured the disturbances. In other cases a partial hydronephrosis from some aberrant vessel was the cause of the pains and hematuria, or a movable kidney, or appendicitis simulated kidney stones. Appendicitis can be differentiated by the pain induced in the cecum by pressure on the descending colon. Again and again, he states, patients sent to the hospital with the diagnosis of appendicitis failed to respond positively to pressure on the descending colon, exculpating the appendix, although there was pain at McBurney's point and the urine was limpid and nearly or entirely free from albumin; a stone impacted in the ureter was responsible for the symptoms. In such cases the apparently normal urine may show microscopic hematuria. On the other hand, pressure on the descending colon may point to the appendix when the colic and hematuria prove to be merely the results of complicating colon bacillus nephritis. The dire effects of an utterly unnecessary nephrotomy in such a case are obvious.

With radiography it is important to inspect both kidneys and both ureters and the bladder as well. The stone may be found in the apparently sound kidney. One man of 40 had symptoms of stones but radioscopy was negative, and yet a catheter in the ureter met with an obstacle which the operation proved to be a stone, and palpation of the kidney showed a cancer in the upper part of the kidney. The ureter was ligated below the stone and the whole mass with the kidney was excised with complete recovery of the patient. One patient seemed to have an actual urate stone factory in his left kidney, the repeated attacks of colic occurring through many years, with the passage of numerous stones up to the size of a pea, but radiography was always negative. The findings were also constantly negative in a man who had a large number of calcium carbonate stones in his right kidney. The negative findings here must have been due to changes in the tissues around. Triple phosphate and urate stones cast faint shadows; in the obese possibly none at all. In thirty-two of 195 cases in which a stone was found at the operation, the roentgen findings had been negative. In six other cases the findings had been absolutely misleading. In four other cases colics from other causes coincided with calcified glands and the latter were mistaken for kidney stones.

In treatment of nephrolithiasis, he advises copious drinking of distilled water, as this washes out the kidneys without depositing more minerals. The patients can take up to 2 or 3 liters in this way, but it must be taken between meals and in small amounts, at most a quarter of a tumblerful at a time. He advises them to get the distilled water from a mineral water establishment instead of from the pharmacy where the water absorbs the odors from iodoform, phenol, etc., which gives the patients a distaste for it. We cannot hope to act on the stones except when they consist of urates and oxalates and are not larger than a pea, but with these, the course of distilled water often realizes a complete success. It is also extremely useful as a preparation for operative treatment in the infected cases and to follow the operation. He waits before operating, unless his hand is forced, to allow this distilled water course to rid the kidney of a certain amount of its toxins and bacteria. This may transform an absolutely inoperable bilateral case into an operable case, and even in the inoperable cases may keep the patients in good condition for years. One woman has kept in good condition during twenty-five years with her 2 liters of distilled water daily, although she still has coliuria and a large stone in the kidney as at first. The distilled water course after the operation is particularly important with the uric acid and oxalic acid diatheses, and it cured the two patients with cystinuria mentioned above—the first time on record in which cystinuria has been influenced by therapeutics. In conclusion Rovsing discusses the various operative methods applied and emphasizes the difference in the outlook according to the bacteriologic findings.

*Treatment of Cancer. S. Nordentoft.—p. 129.

Jan. 30, 1919, 81, No. 5

*Lessons from War Restrictions in Food, M. Hindhede.—p. 183.

Treatment of Cancer.—Nordentoft regards as great progress the result of recent research by Kaminer and others showing that malignant growths can be influenced by serum and organ extract treatment; also that the diet has an influence on the growth of cancer. Thymus extract in particular seems to destroy cancer cells in vitro, even when diluted twenty-two times, or destroys 55 per cent. and 32 per cent. diluted twenty-three and twenty-four times. This suggests the possibility of destroying cancer in the living body by injection of thymus extract, which may also aid in elucidating the etiology. He adds that the best results to date with thymus extract have been obtained with fresh, unheated thymus extract. His own experience with it is still too recent for a final decision, but the patients bore daily injections of 10 c.c. without signs of intolerance, no general or local reaction or anaphylaxis. Denmark has no general institution for cancer research, and he urges others to follow this promising line of study, investigating the physiology of the thymus at different ages, the behavior of the thymus in persons with cancer, the effect of thymus extract on incipient cancers, and the species of animals that yield the most effective thymus extract; dog thymus to date has shown greater cancer destroying power than rabbit thymus. The thymus extract should be standardized and the essential principle isolated if possible. It will be interesting to see how injections of thymus extract affect the inoculability of mouse and rat cancers, and whether preliminary injections of thymus extract will ward off the development of Fibiger's nematode cancers in rats, and the Japanese cancers in rabbits, and, finally, whether they may not prove effectual in warding off recurrences in man after operations or radiotherapy.

The Wartime Food Supply.—Hindhede compares the food conditions in Germany and in Denmark during the war, saying that the war experiences have proved a test on an infinitely huge scale of the Voit-Rubner views of an adequate dietary as opposed to the Chittenden-Hindhede views. The food supplies in Germany should have been mobilized and managed on a true scientific basis, as efficiently as the military affairs. Instead of that, the farmers let their brothers in the cities starve while they fed their pigs. Ballod in Germany in 1917 confirmed Hindhede's assertion in 1915 that the German pig was perhaps the most dangerous of the forces with which Germany had to contend. In Denmark, on the other hand, the food commission consisted of four scientists (including Hindhede), and four representatives of the farming interests. All agreed that to feed grain and potatoes to cattle and swine meant a loss of at least 80 per cent. of the nutritional value. The logical consequence was the requisitioning of all the bread grain, of most of the barley, and of a large proportion of the potatoes, for food for the people. The stock of pigs had to be reduced to one third or even, in some places, to one tenth, but this did not frighten the commission. They insisted on reserving enough food for human beings and a 30 per cent. excess. The farmer members of the commission—taught by the evil experiences in Germany—accepted this plan, and their unanimous approval brought the whole country, town and farming districts alike, to approve and accept. The stock of cattle has dropped from 100 to 65 per cent. and of pigs from 100 to 17 per cent. The farmers ceased to lament the loss of their stock when they saw the dire effects in Germany of the opposite policy. The city people regretted the scarcity of meat, but they rejoice now that there has been no starvation and that the public health in general is in the best of conditions (apart from the influenza). Hindhede remarks in conclusion, "The German soldiers conquered France in 1871 with the aid—or in spite of—three fourths of a pound of meat a day, and they went into the present war on the same basis. Germany has paid a high penalty for clinging to the antiquated Voit-Rubner ideas of an adequate dietary."

TROPICAL DISEASES OBSERVED IN SIAM

RALPH W. MENDELSON, M.D.
Member American Red Cross Sanitary Commission to Serbia, 1915;
Sanitary Expert, Royal Siamese Government, 1916-1918;
Formerly Captain, M. C., U. S. Army
DES MOINES, IOWA

As the Central Hospital of the city of Bangkok came under the administration of the local sanitary department, it afforded an excellent opportunity to observe and study various tropical diseases as they appeared in the outpatient department of the hospital. In the different textbooks on this branch of medicine, seldom if ever does one see a reference to Siam; and it is thought that a short paper on the more important diseases observed may be of interest.

SKIN DISEASES, INCLUDING ULCERS

Of the pyogenic infections little need be said. They are very common as in other tropical countries, with special reference to pyosis mansoni and purulent folliculitis of the various parts of the body.

The great majority of the skin diseases found come under the simple dermatomycoses, and of these the most common one observed was tinea flava. A few cases of tinea imbricata appeared. Several cases of sporotrichosis have been treated with mixed iodids resulting in the complete disappearance of all lesions. Only one case of mycetoma has been seen, which was in a native Siamese—a case of long standing, affecting the foot. The sclerotia were yellowish white and of different sizes. Local treatment and general medication produced no results, and amputation was advised; but the patient refused, and the case was lost sight of.

Several cases of juxta-articular nodules have been seen, in two of which the nodules were located in the gluteal region. The patients were all Siamese, and I have seen no cases in Chinese. It is possible that the habit of sitting on the haunches is a predisposing cause to the gluteal regions being affected.

With regard to ulcerations, I have lately finished the examination of 100 ulcers as they appeared in the clinic for treatment. A digest of my paper on this subject appearing in the government Red Cross medical journal may be of interest. Eggers[1] reported on the examination of 2,874 specimens and found that 9.3 per cent. were positive for spirochetes of one or more types. I followed his method of staining so that the results might be compared. Eggers' Type A spirochete is thus described:

> A long, tenuous organism, which typically possesses from three to four complete, regular convolutions of considerable amplitude. It is on an average 13 microns long, but varies considerably from this figure in both directions. As a rule it takes a bluish stain with Giemsa's solution (stained twelve hours).

This organism he considers the typical organism of tropical ulcer. My results are given in the accompanying table.

Thus of 100 ulcers, 10 per cent. showed spirochetes all of Type A (Eggers). From these results I am inclined to look on this organism, which corresponds to *Spiroschaudinnia schaudinni* Prowazek 1907, as a superimposed infection on an ulceration. Certainly this spirochete was not limited to a disease of distinct clinical features; in fact, it was to be found in a variety of diseases with great variations in clinical features. It is of interest to note that in two of the ulcers typical Leishman-Donovan bodies were found; consequently, a diagnosis of oriental sore was made.

Of the dermatozoiases I have had a case of dermatitis macrogyrata in an ambidextrous Chinese carpenter. The patient was advised to stop all work and to keep the hands covered with ointment of phenol and well bandaged. A marked improvement has attended this treatment.

CLINICAL DIAGNOSIS AND LABORATORY FINDINGS

Diagnosis	Spirochetes	Type (Eggers)
1. Tropical ulcer	Positive	A
2. Tubercular ulcer	Positive	A
3. Varicose ulcer	Positive	A
4. Ulcus infantum	Positive	A
5. Undetermined ulcer	Positive	A and Leishman-Donovan bodies
6. Syphilitic ulcer	Positive	A
7. Tropical ulcer	Positive	A
8. Tropical ulcer	Positive	A
9. Tropical ulcer	Positive	A
10. Undetermined ulcer	Positive	A and Leishman-Donovan bodies

Two typical cases of keratoma plantare sulcatum have been seen. They both gave a history of almost complete recovery during the dry season, but during the rains and especially the last flood season, the disease appeared in all its severity. The deep creases and the typical punched-out holes were quite evident on the soles of the feet. Keeping the feet dry and covered with ointment of phenol had a good effect.

Leukoderma and albinism are extremely common, as well as chloasma of the various types.

Of the tumors, rodent ulcer has been seen in a native. Keloids and fibroma molluscum are common. Ichthyosis is very common.

PLAGUE

Plague is endemic, and hundreds of persons succumb to it every year; but fortunately the government is now awake to the danger, a royal plague commission having but recently been appointed to consider ways and means to control it. I have seen no cases of pneumonic plague in human beings; but having had occasion to examine a number of cats that had died suddenly in and near a large government institution, I found they had died from pneumonic plague.

---

[1] Eggers: J. Infect. Dis. **16**: 269 (March) 1915.

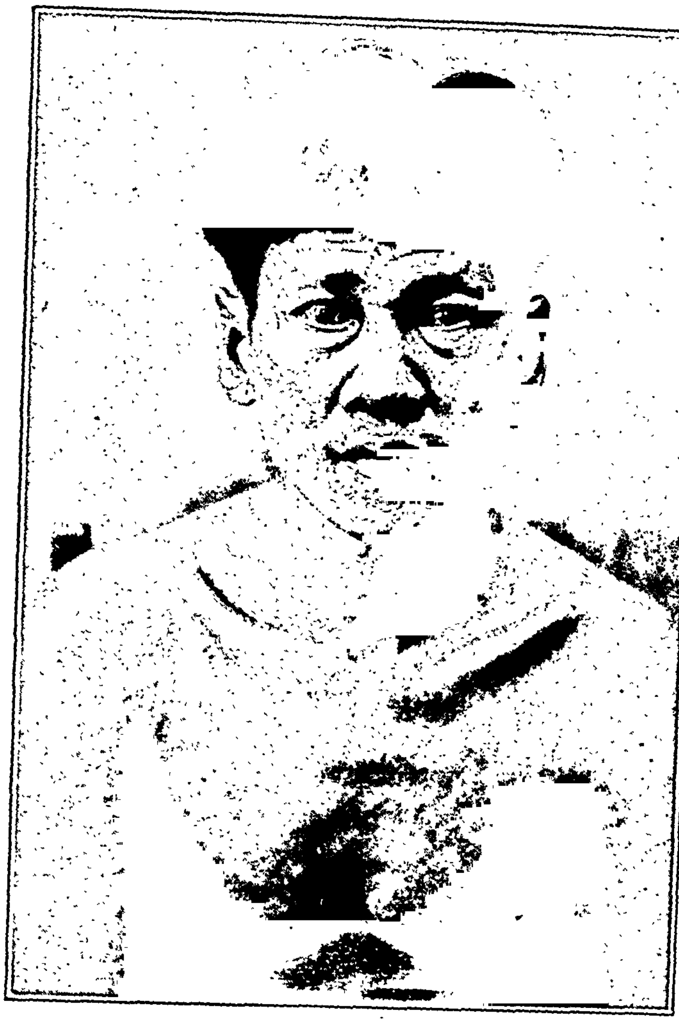

Fig. 1 (Case 3).—Leprosy: appearance of patient in April, 1917.

The ambulatory type of bubonic plague is common, and in this connection I wish to mention two cases that are of interest.

Case 1.—A boy, aged 18 years, who came to the outpatient department complaining of an injury to the palm of the right hand, had fallen two days previously, and a splinter of wood had entered the palmar surface of his hand. There was a rise in temperature of 1 degree, and a very slight amount of swelling of the hand. The glands were not enlarged. The patient complained only of "stiffness in the hand." He did not look ill, and plague was certainly not thought of. The hand was treated surgically, and for some unaccountable reason the patient remained in the hospital for treatment, as usually these minor injury cases are sent home with instructions to return for treatment. In twenty-four hours this boy died, and a postmortem examination revealed a septicemic plague.

Case 2.—A man who came to the outpatient department on account of an injury to his right foot was suffering from an open wound of several days' standing with a dirty discharge. The patient felt well, had a temperature 2 degrees above normal and there was a slight bubo in the groin. This was examined for bipolar-staining bacilli, and as these were found, a diagnosis of plague was made and the patient sent to the plague hospital, where he recovered.

The suppression of plague in Siam presents many difficulties, of which the religion of the country constitutes the first and foremost. The Buddhist religion forbids the taking of life. I do not attempt an explanation of the taking of human life during war; suffice it to say that it is impossible at the present time to get a Buddhist to kill a rat. Also one has to fight "vested interests." The erection of rat-proof buildings, and sanitary measures as a whole encounter great opposition, and sad to say, the Europeans are as bad as the natives when it comes to blocking improvements. Again, the little item of available funds is rather perplexing; as a matter of fact, not only must one overcome the foregoing difficulties, but one should possess a large stock of faith, hope and charity; then the plague problem might not look so big.

KALA-AZAR

I have seen only one case of kala-azar. Jan. 31, 1918, a native-born Siamese who had never been out of the country appeared in the outpatient department for treatment, complaining of "weakness and swelling." He was advised to remain in the hospital under observation, which he did. After several examinations, the parasite *Leishmania donovani* was demonstrated. The patient died after being in the hospital one week, and a postmortem examination disclosed a large, red spleen in which parasites were easily demonstrated. Although this is the only case I have seen, and have heard of only one other case, yet dermal leishmaniasis is not uncommon. At least 2 per cent. of all ulcerations coming under my observation showed *Leishmania tropica.*

FILARIAL DISEASE

Filarial disease is not uncommon, as is evidenced by the unsightly deformities appearing for treatment. It is an easy matter, comparatively speaking, to demonstrate the microfilarias, because the native Siamese has a habit of sleeping in the day and doing what little work he does at night, which is not such a bad idea, considering the extreme heat of the day.

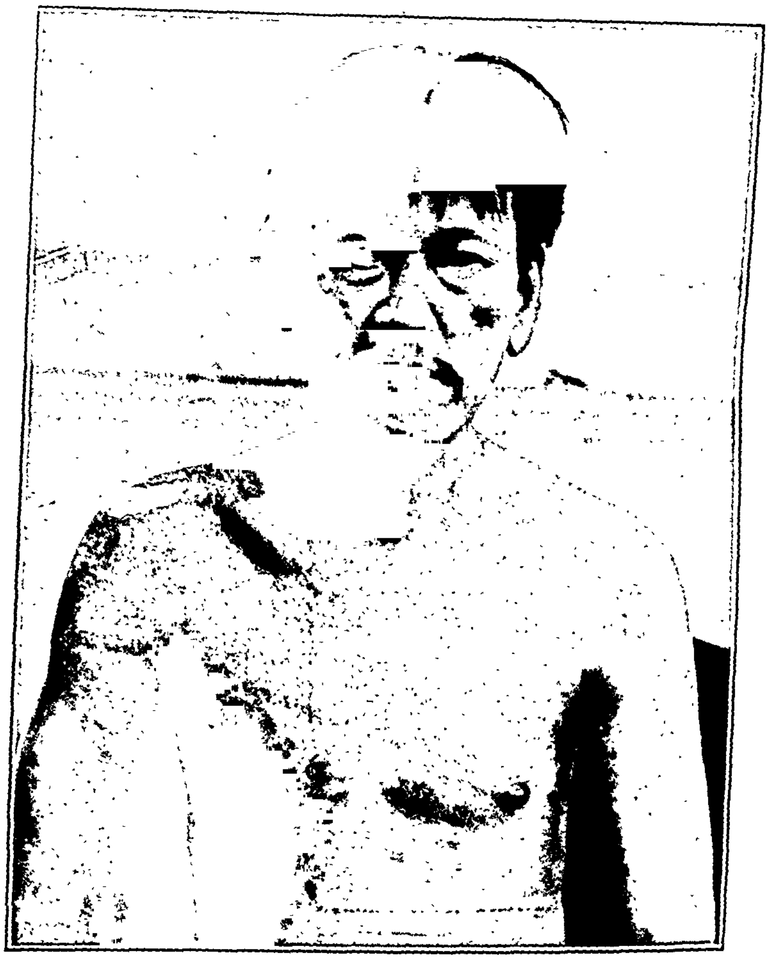

Fig. 2 (Case 3).—Leprosy: appearance of patient one year later, April, 1918.

We have had elephantiasis of the lower extremities and the scrotum, filarial abscesses, hydrocele and other complications. I have had several cases of what is known locally as "Bangkok fever," the blood examination revealing a filarial infection, with or without a malarial infection. I recently saw a man, one of the better class Siamese, who complained of a rupture. His swollen leg of long standing caused him no anxiety; being not greatly enlarged, it did not interfere with locomotion, but the swelling in his groin worried him. On examination a distinct swelling, soft and producing an impulse on coughing, was made out. But it would not completely disappear when the patient reclined, and also a blood examination showed microfilariae. Puncture revealed lymph; microfilariae could not be demonstrated.

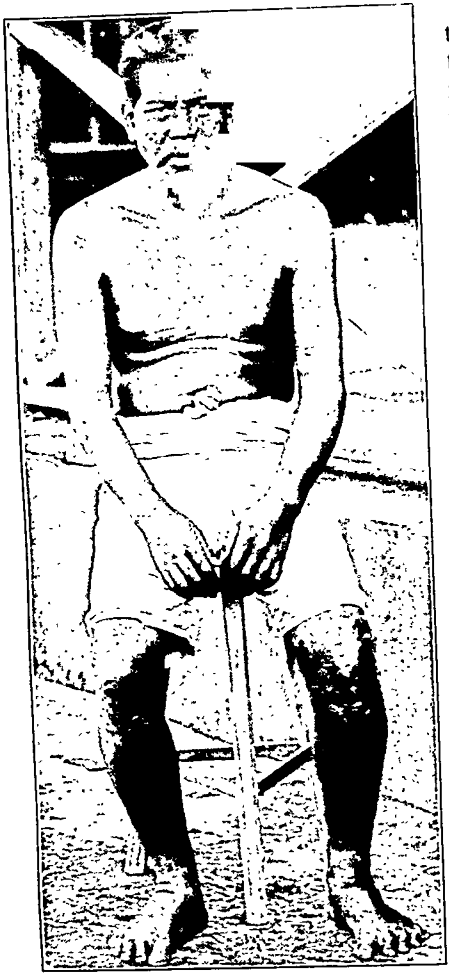

Fig. 3 (Case 4).—Leprosy; front view of patient in October, 1917.

LEPROSY

It is estimated that there are in Siam no less than 5,000 lepers. At present no effort is being made by the government to segregate or to treat these people. The various missionary doctors are doing good work, but unfortunately only a small percentage come under their observation. It is hoped that the government will in the not distant future find it possible to build a leprosarium.

Every type is represented, and, as far as I could see, the cases were about equally distributed among the various races that one finds. Rogers' new treatment is being tried out by several men, and good results are reported; but it is too soon to make comments on final results.

It is peculiar that while some observers report most promising and even lasting results with Rogers' treatment, others report exactly the opposite. It would seem advisable, when a new treatment is brought forth for a disease such as leprosy, to appoint an international commission to report on it, and if it is found of value, to insist, so far as that is possible, that those afflicted be given the benefit of such treatment. Too often the medical profession either jumps at conclusions (this may sound rash, but it is a fact) or is influenced by conditions quite foreign to the subject under consideration.

CASES OF LEPROSY TREATED WITH SODIUM GYNOCARDATE AND SODIUM GYNOCARDATE "A"

These cases are reported through the courtesy of Dr. M. Carthew, Assistant M. O. H., Bangkok, Siam.

Case 3.—The patient had had leprosy two years, when first seen in April, 1917, and had been in prison for three years, so that it appeared that he had been infected in prison. His body and face were covered with red maculae of varying sizes; some had pale centers. There was an extensive dermatitis of legs and feet and arms. The hair had fallen out of both eyebrows, and the eyelashes were very scanty. There was ptosis of the left eyelid and absolute anesthesia of arms, hands, legs and feet. The bacteriologic examination of the nose was positive. The diagnosis was: maculo-anesthetic leprosy.

In April, 1918, the small scattered maculae had all disappeared with the exception of one or two remaining faint red marks on the back and the abdomen. The dermatitis was much improved except over one shin bone where it was in the same condition as a year before. The eyelashes were now normal. The eyebrows had grown, and the mustache and the beard were now growing freely. The anesthesia of legs and feet was improved, but the condition was not yet normal. The patient could feel pinching but not stroking merely. The feet remained partially anesthetic. The anesthesia of the hands and the arms had completely disappeared with the exception of one small spot on the left outer arm below the elbow where a fresh reactionary swelling seemed to be just breaking out. His general health was now normal, and he never suffered from acute joint pains. The result was considerable improvement.

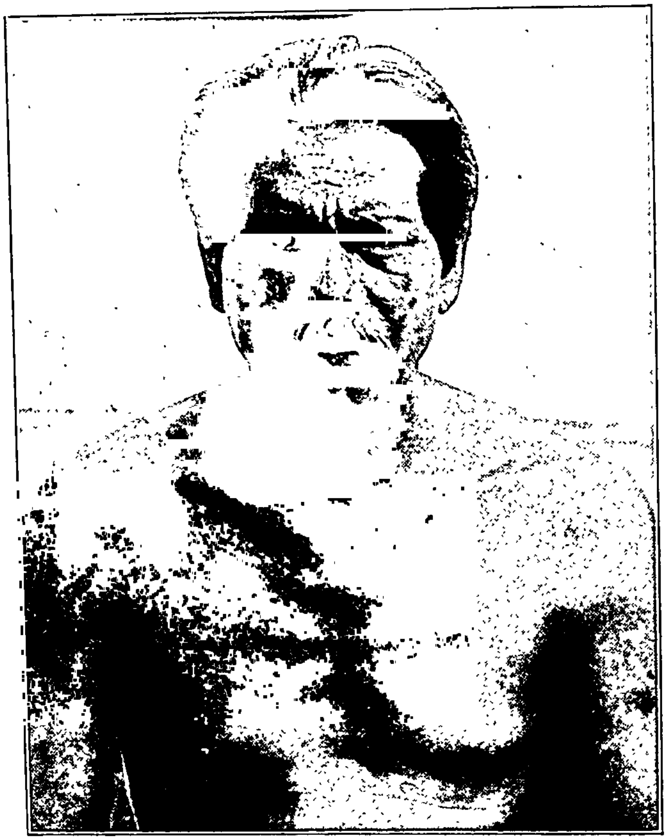

Fig. 4 (Case 4).—Leprosy: front view of patient in April, 1918.

Case 4.—The patient had had leprosy fifteen years, when first seen in October, 1917, and had been in prison seven years, during which time he had not been isolated till eight months previously. The patient's whole body and face were covered with disseminated tubercles. There were dark red maculae (almost black) on the face, chest, back and right lower leg. These had distinctly raised margins. There was a dark, large, red macule on the back with raised edges showing extensive scaly dermatitis. There was complete anesthesia of all above-mentioned maculae, also of the outer side of the right foot, of the inner side of the left foot, and of the right wrist. The diagnosis was mixed leprosy.

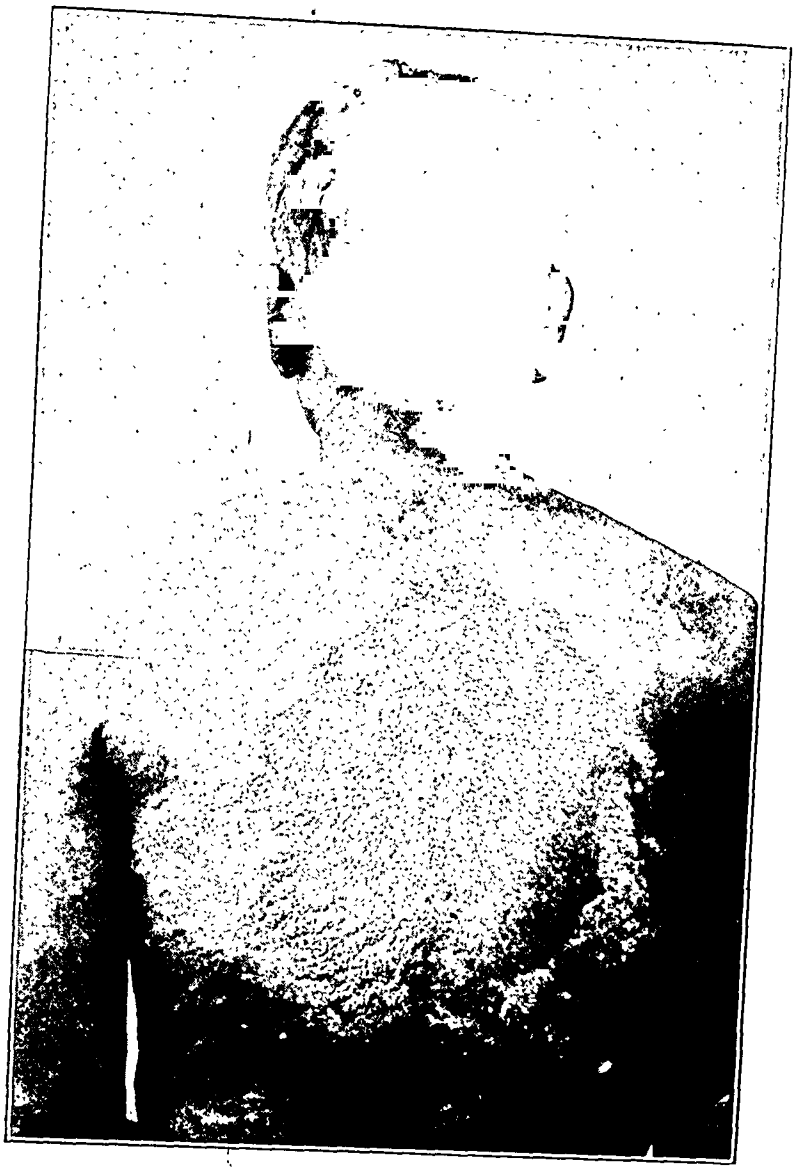

Fig. 5 (Case 4).—Leprosy: dorsal view of patient in October, 1917.

In April, 1918, namely, after seven months' treatment, all tubercles and the dermatitis had completely disappeared, but some of the macular thickening remained. The maculae on the face were much reduced in size and were of almost normal color with two exceptions. As regards anesthesia, sensation had returned in all maculae with the exception of a 2-inch patch on the back and a similar patch on the outside of the right foot. The patient's general health had much improved. The results were that the lesions were markedly improved.

MELANOTIC SARCOMA OF CHOROID

Case 5.—A Siamese man, aged 32, presented himself at the clinic with a melanotic sarcoma of the choroid of five months' duration. There was metastasis to the parotid gland. There were no signs nor symptoms of any other disease. An operation was performed and the patient made an uneventful recovery.

FRAMBESIA

Frambesia is very common in Siam. Most of the cases seen in the clinic have been in children and in young adults. Unfortunately the patients do not come for treatment until the disease is far advanced. The clinic is not in a position to treat the patients with arsphenamin, but very good results have been had with liquor potasii arsenitis (Fowler's solution). I have my doubts as to the permanent results from the foregoing treatment, but so far no patients have returned, and far be it for a native to continue treatment after the signs and symptoms of disease disappear.

SYPHILIS

Syphilis is rampant in Siam. A native coming to the clinic invariably diagnoses his own case, and unfortunately he is not as a rule far off. But of the hundreds of cases of syphilis that I have seen, only three cases of syphilis of the nervous system have been noted. My experience as a member of the American Red Cross Sanitary Commission in the Balkans was the same. Various attempted explanations have been given, and I have thought that a race or people whose nervous system is not so "keen" as that of the modern twentieth century man might be more resistant, or perhaps not so susceptible, to the syphilitic virus. I might mention here that pellagra is not uncommon at all, but I never saw a case with nervous manifestations, and I felt sure that my explanation was soon to become an established fact, namely, that these dull nervous systems are not affected as a rule by the various poisons that do produce effects on more highly developed nervous organisms. But in view of the nervous manifestations of leprosy, beriberi and other diseases encountered, my explanation immediately loses force.

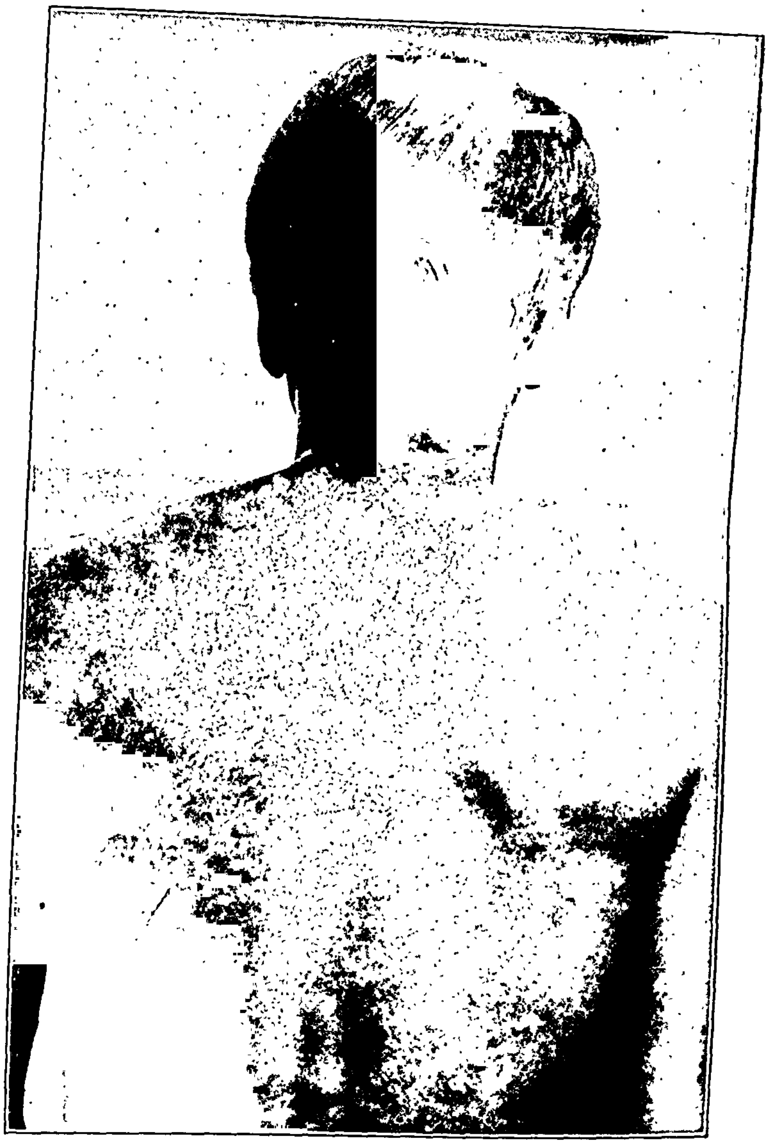

Fig. 6 (Case 4).—Leprosy: dorsal view of patient in April, 1918.

BERIBERI

Beriberi is very common in Siam. The great majority of the patients appearing in the clinic for treatment are policemen. They all give a history of having eaten polished rice. Most of the cases are of the dry type. These patients invariably refuse to remain in the hospital, but return home, as they usually receive from one to two months' leave, depending on the severity of the case. Most of them return in perfectly good condition because, living up-country, where the only rice they get is hand-milled, they get along very well without any other medication. I even suspect that, although they are impressed with the dangers of a diet of polished rice, they deliberately resume such a diet on their return to Bangkok in order to get sick and thus get sick leave.

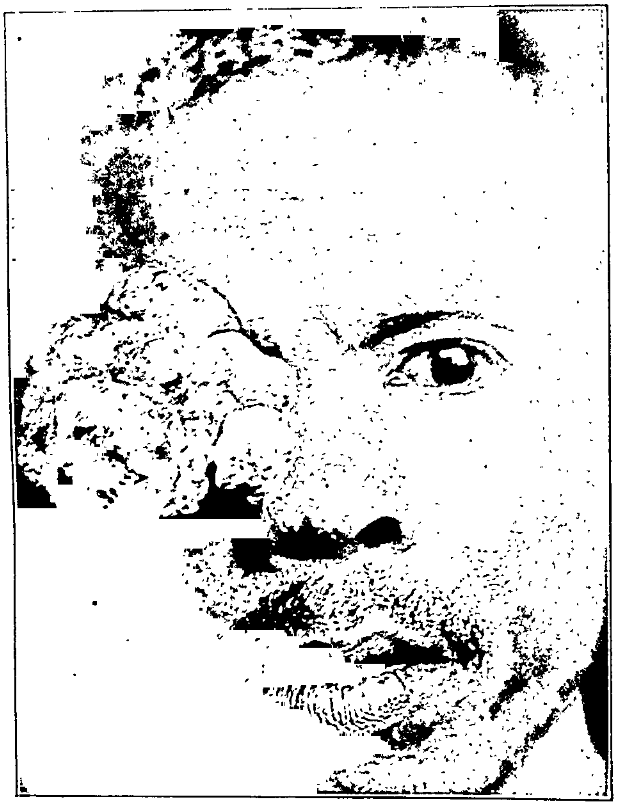

Fig. 7 (Case 5).—Melanotic sarcoma of choroid: front view of patient on entering the hospital.

PELLAGRA

As stated above, pellagra is not uncommon. The usual history is that of a recurring dermatitis during the hot season, as a rule limited to the hands and feet. The gastro-intestinal history is never lacking; and although gastro-intestinal difficulties are exceedingly prevalent in a tropical country, yet the most typical lesions and history establish the diagnosis beyond a doubt. These patients are never entirely free from the dermatitis, but during the "cold season" they are so very much improved as to consider themselves quite free from any irritating skin disease.

FEVERS

I found that in Bangkok malaria was extremely common, although it is commonly held that while up-country a great deal of malaria is to be found, in Bangkok such is not the case. I took particular pains to investigate the matter, and I found that between 20 and 25 per cent. of all blood films examined showed distinct evidence of malarial infection. These cases are practically all from the Central Hospital, and I think they represent very well the incidence of malaria in the city of Bangkok. I have seen no cases of pernicious malaria, the great majority of the cases being of the chronic subtertian type. Complications are not common.

In the prevention of the disease it is not to be expected that the native will take all of the precautions that the European will take, yet they all sleep under mosquito nets. The point I wish to make is that Europeans, at least the Europeans living in Bangkok, do not take the necessary precautions. I know of only one house in Bangkok that is screened. I occupied apartments in the Oriental Hotel, and up to the time of my arrival, although the hotel had been doing business several years, not one room in the entire building was screened. My screened apartments made a great "hit," and now the occupants of several of the other apartments are following suit.

BLACKWATER FEVER

Blackwater fever is seldom seen except up-country, where I understand it is not uncommon. I have seen two distinct cases in the city of Bangkok. One was imported from the hill country, and the other patient was a city dweller. Both patients recovered.

RAT-BITE FEVER

A number of cases of rat-bite fever appeared in the clinic. The cases were not unusual, and as stated above, in connection with frambesia, it being impossible to treat these spirochetal infections with arsphenamin on account of a lack of supply, liquor potasii arsenitis was the next best agent to be had at the clinic, and the results were satisfactory if not spectacular.

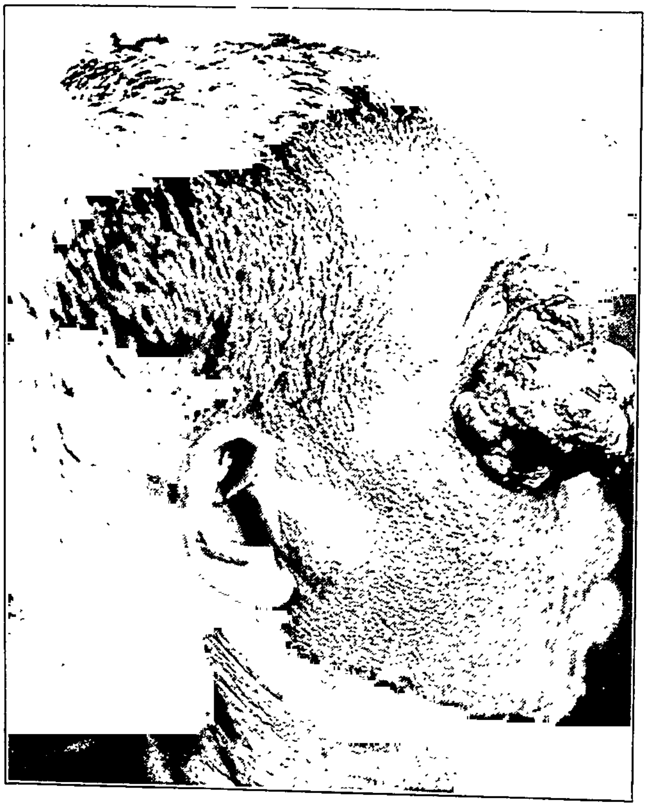

Fig. 8 (Case 5).—Melanotic sarcoma of choroid: side view of patient on entering the hospital.

DENGUE AND ALLIED FEVERS

Dengue is epidemic every year and plays havoc with the European population. The natives do not seem to suffer so much from it.

Phlebotomus fever is not uncommon. I have seen several cases in Europeans and many in the clinic. It usually runs a course of between twenty-four and thirty-six hours. Symptomatic treatment is the treatment so far and produces good results. The natives think a physician is especially clever to make it clear up in twenty-four hours.

RELAPSING FEVER

Relapsing fever is not very common; at least, that has been my experience. I had only two cases in which I could demonstrate the causative agent. These cases were both in native Siamese who had never been out of the country. One appeared, Feb. 3, 1918, and the other, May 13, 1918. Neither of the patients was acutely ill, and both complained of having been sick for several weeks. Continued observation was confirmed by blood examinations, and appropriate treatment produced satisfactory results. There were no complications except that one patient had a severe bronchitis that had not completely disappeared at the time he left the hospital.

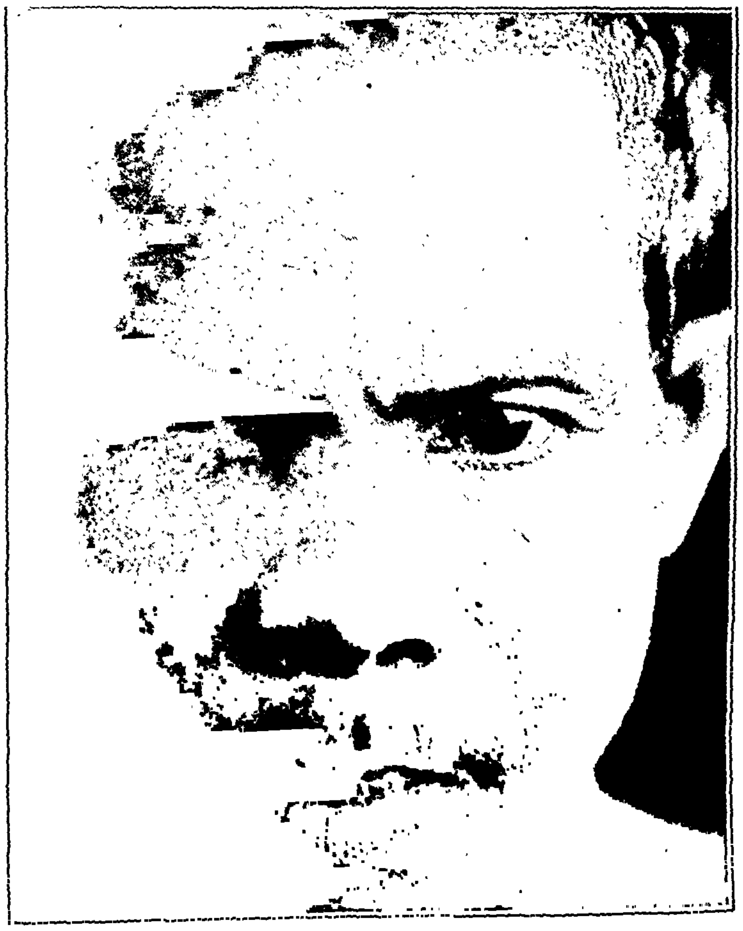

Fig. 9 (Case 5).—Melanotic sarcoma of choroid: appearance of patient on leaving the hospital.

TYPHOID FEVER

I myself have not seen a case of typhoid fever in a Siamese. Certainly there is typhoid fever there, and I have heard of cases, but I have not seen one in the clinic, and blood examinations have all been negative in cases that were remotely suspicious. I think that I am safe in stating that it is very uncommon, and the explanation is that the native has acquired an immunity. He lives on sewer water from birth, and if he is able to survive his infancy he is able successfully to fight almost any kind of intestinal infection. The European, on the other hand, drinks only bottled water and deep well water, and is the one who develops typhoid when exposed to infection. The only cases I heard of were in Europeans.

DYSENTERY

Dysentery is very common in Siam, both amebic and bacillary. An immunity for the dysenteries does not seem to have been acquired to such an extent as it has for typhoid. The combination of chronic amebic dysentery and opium smoking produces a pathologic syndrome that is hard to describe. Either one is bad enough, but the two together make a choice bit for the pathologist. My limited experience with emetin bismuth iodid has been most satisfactory.

INTESTINAL PARASITES

Intestinal parasites are very common, as in all tropical countries (the ameba being considered under the dysenteries). Ancylostomiasis is very prevalent, especially in the north, where, at the present time, an intensive campaign is being carried on by the International Health Board of the Rockefeller Foundation under the directorship of Dr. M. E. Barnes. The immediate results are very satisfactory, but unfortunately the government is not whole-heartedly in the scheme; consequently, permanent results cannot be expected. This is unfortunate, for if the Siamese government had been approached in the right manner originally, no doubt better results could now be expected in the important matter of prevention of reinfection.

CHOLERA

I have seen no cases of cholera, although a few years ago cholera was endemic and quite often epidemic. It is a fact that since the city has built the new and up-to-date water-works, cholera has disappeared. Now it so happens that the perfectly good city water supply does not supply the entire city. As a matter of fact, that part of the city of Bangkok that lies on the east side of the Menam River is not supplied at all, and many parts of the city proper still use the dirty water of the river; therefore, it cannot be said that the new water supply did away with cholera; it simply disappeared.

OTHER DISEASES

Next to venereal diseases comes tuberculosis in the matter of high rate of admissions to the outpatient department. Tuberculosis presents all of the complications. When I say tuberculosis I have in mind pulmonary disease. The Chinese seem to suffer more than the others. I think this is due to the fact that they insist on living on top of each other, so to speak. The other races, although crowded and dirty, do not occupy such terribly congested places as the Chinese. But at night they shut up everything tight, pull down the mosquito net, and proceed to infect each other by spitting, coughing and breathing the most foul air, and it is impossible to impress on them the necessity of pure air, sunshine, and other hygienic and sanitary measures. In regard to lung infections, I might state that pneumonia is not uncommon, especially among the soldiers. I think this is due to excessive training in the paddy-fields, the soldiers being made to remain for long periods of time in pools of water and other places equally bad; and often at night, when it gets quite chilly, one can see them tramping through the muddy fields on their way to the barracks. They immediately go to sleep without changing, and naturally many of them are taken ill.

I have seen a number of cases of bronchial spirochetosis, and while examining a number of cats for suspected plague I found one that had died of a lobar pneumonia, a mixed infection in which a spirochete that took the ordinary stains predominated.

VENEREAL DISEASES

By far the greatest number of cases seen in the clinic are venereal. These patients all come in after the disease has become chronic, and few of them return often enough to get cured. Complications are common, as is evidenced by the number of infants with eye infections.

In this connection I wish to mention a disease which, although not venereal, can be conveniently put under this heading, namely, climatic bubo. I have seen a great number of these cases, all presenting buboes in the groin, giving no history of any venereal infection, and a native's word in that respect can be taken, because he thinks nothing at all of such a disease. The cases come late; there is very seldom an acute case. The buboes are usually quite large, firm and not very tender, except in the acute cases. I have aspirated many of the patients just mentioned, and in every case in which a definite nonvenereal history has been given and in which there are no signs of infection on or near the parts, I have been unable to discover any organism. Symptomatic treatment is advised; the results are sometimes good and sometimes otherwise. In old, chronic cases, excision is the best treatment.

TETANUS

The French Hospital in Bangkok averages one case a day of tetanus in the new-born. How many cases must there then be every day in the whole of Siam? The patients with tetanus at the French Hospital are mostly Chinese, the mothers bringing the infants for burial more than for treatment, as they are superstitious about having a death in the house. The death rate is 100 per cent. On the contrary, tetanus is not very common in adults; there have been only two cases in the clinic during the last year and a half. This is interesting because practically all of the emergency surgery cases present dirty wounds, the native coming to the clinic with an old ulceration completely covered over with manure. A "manure plaster" is a household remedy. It seems that the adult has acquired an immunity to tetanus, but unfortunately this immunity is not transmitted to the offspring.

LEAD POISONING

I have had a number of cases that presented all the signs and symptoms of chronic lead poisoning, except the lead line. But this is explained by the fact that the natives chew betel nut, which leaves a deposit on the teeth and gums that is sometimes appalling in amount. I admit that the diagnosis in the first case or two was made by exclusion, but on inquiry I learned that all of the patients came from the same part of the country and that this particular district is noted for its huge deposits of lead, the natives evidently drinking the lead-laden water, or otherwise getting into their system the lead from these deposits.

Typhoid and Carriers.—Expect to trace every case of typhoid to contact with a carrier, either during or after a clinical or unrecognized course of the disease in the carrier.—*Weekly Bulletin, A. E. F.*

SYSTEMATIC CARE IN THE SEXUAL DISEASES *

JAMES BAYARD CLARK, M.D.
Major, M. C., U. S. Army
NEW YORK

In practically all but one branch of medicine, when the war broke out, there was a fairly well defined system which governed and held together the work of each department, and served as a basis whereby it could be lifted up, whole, as it were, and transferred into the army service as a useful and workable unit.

General surgery, for one, was well organized and prepared at once to begin creditable war work. The pathologic laboratory was laid out along such precise and practical lines that it was carried over with ease. Internal medicine, as ever, knew its way about and was ready on short notice to be mustered in and play its part; but the department of medicine which dealt with genito-urinary ills, the very one which was so sorely needed (and the one which will for a long time still in civil life be sorely needed) somehow or other did not seem to be held together in the same portable sense as the others. So the Medical Department of the Army was constrained to collect such loose pieces of this particular branch as could be found, and cement them into the semblance of a specialty and courageously meet the situation to which necessity and a drafted army gave such sudden birth. Since that time there has developed in our camps and cantonments and in our service abroad much that will go to make up a useful beginning in that campaign against the sexual infections which is now plainly ahead.

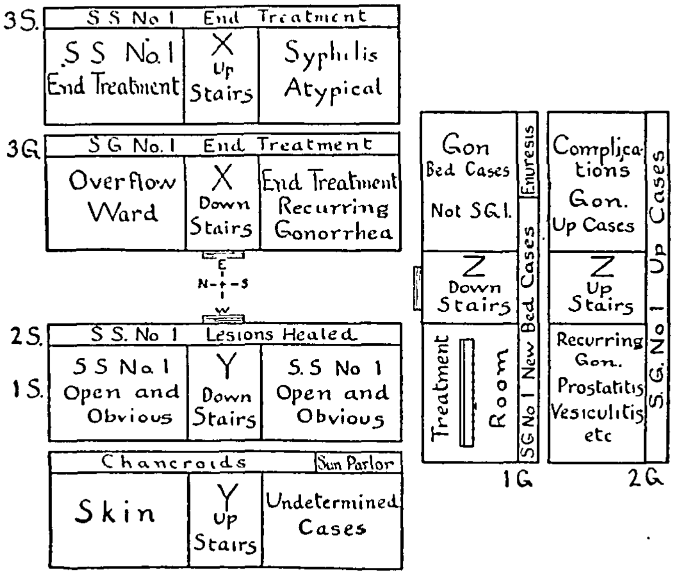

Fig. 1.—Floor plan of Buildings X, Y and Z, showing the promotion of patients according to their progress toward recovery.

THE WORK AT CAMP LOGAN

What has been done at Camp Logan to put the collective care of these infections on a rather more orderly basis, as well as to develop somewhat the prophylactic part of the work, is given with the hope that in some degree it may serve as a start for further development along the lines aimed at, which, failing prevention, are intended to encourage the treatment of these diseases at the earliest possible period of their onset, and by such means as will materially shorten the period of infection as well as give a more definite assurance of completeness of cure.

---

* Owing to lack of space, this article is abbreviated in The Journal by the omission of several illustrations. It will appear in full in the author's reprints.

To lead the reader more agreeably as well as more graphically through the different departments and their workings, the steps in its description will be left as much as possible to illustrations and as little as possible to verbal explanation.

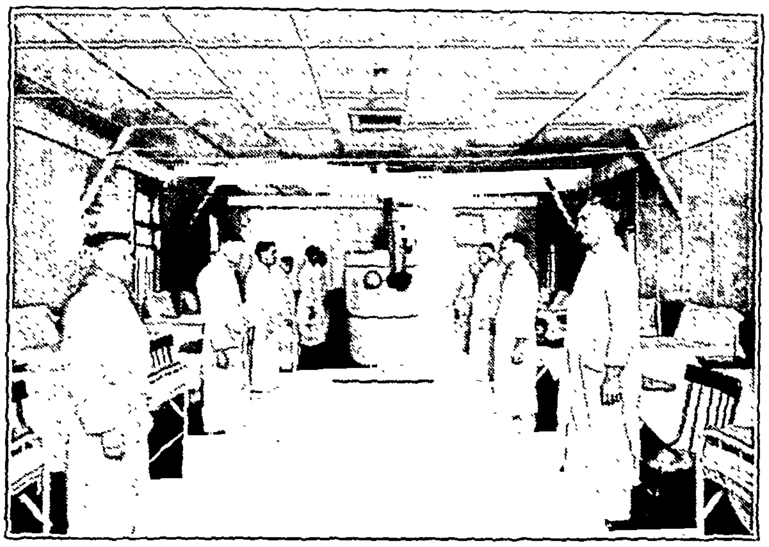

Fig. 4.—Typical ward.

The genito-urinary service, as it is now established at Camp Logan, may be looked on as a hospital within a hospital, and one that could be separated and act as an entity in an army camp or a community with but little modification or addition. One essential addition, if our plan were to be duplicated on an independent basis, would be a laboratory for the serologic and some other of our pathologic work which we have done in the central laboratory. Another addition would be an operating room equipment.

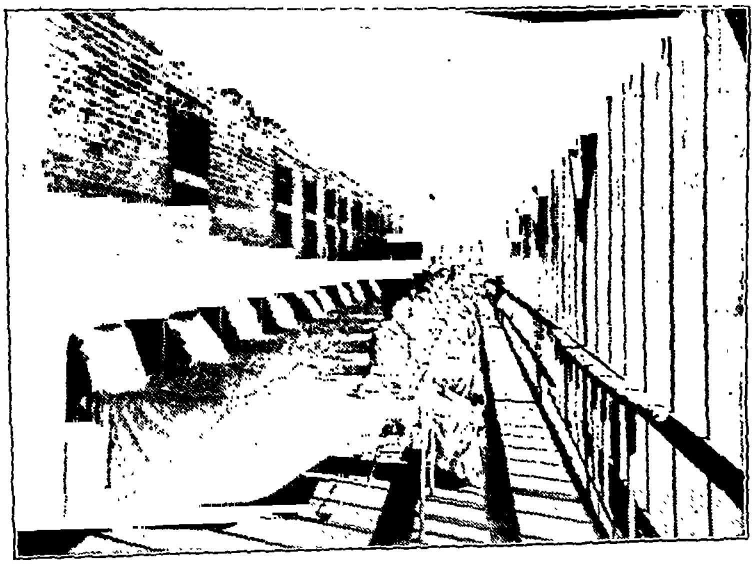

Fig. 5.—Typical porch.

Our bed capacity is about 300, divided between three two story buildings. The schematic floor plan (Fig. 1) shows how the patients are divided into ward groups according to their disease, and according to their progress toward recovery. This is a great simplification in the matter of diagnosis and treatment, and it serves as an encouraging stimulus to the patient as he graduates toward his cure. The plan also makes it easy for the ward surgeon to memorize accurately his patients and their conditions. On the upper floors are the "up" patients. This arrangement effects an economy, as no meal trays have to be carried upstairs, the "up" patients being able to go to mess. It is also a safeguard in case of fire, as these patients are all able to get away without requiring assistance.

Perhaps the best way to get a mental picture of the whole would be to make with me an imaginary daily round according to the usual routine.

By keeping the schematic floor plan in mind, the relation of the Buildings X, Y and Z will be remembered as they stand on three sides of a square. We start with Building X, on the left of the square. As we enter at 8:30 in the morning, our entrance is a signal for the morning assembly of ward surgeons, nurses and the ward men of that building (Fig. 2).

The conference serves several purposes: We start the day by a "good morning," and see that every one is present. Reports from the different heads are heard. The aim of our work, the policy of the proceedings, and the details, if necessary, of our duties are discussed. We have *no* secret diplomacy; we all know what we are heading for. In this way we all do our work happily and keep our balance.

Jan. 4, 1919. Disch. to duty.
IRBancroft, Capt. M.C.

One month rest then take Wassermann, if positive, repeat entire course; if negative, repeat the Hg. alone.

At end of second course, rest two months, then take Wassermann and give third course in accordance with rule for second course.

During second year, if Wassermann is positive, repeat entire courses as above. If negative, give two Hg. courses with four months between.

Fig. 8.—Syphilitic register stamped with Standard Syphilis No. 1.

This morning line up is usually only a matter of a few minutes, and is followed by a rapid inspection of the building and equipment. Next we go to Building Z and then to Building Y, for the same line up and inspection. When inspection is made, particular attention is paid to the appearance of the patients, especially the "up" patients; for to be clean and freshly shaved, neatly dressed and shoes polished means self respect, and that means quicker recovery and a better soldier or a better citizen, as well as better deportment while in the hospital. A barber shop (Fig. 3), where surgical cleanliness is actually carried out, was installed for the use of the patients on this service.

After inspection in Building Y is completed (9 o'clock), professional rounds are begun at this point (Figs. 4 and 5). This building is for the care of syphilis, chancroids and skin cases. With a study of the forms here illustrated, which guide and control our treatment of syphilis, only a brief explanation will be necessary. With the formula Standard Syphilis No. 1 will be seen the procedure followed in all ordinary early cases. I am indebted to Col. L. W. Harrison, D.S.O., K.H.P., for much of the groundwork of this plan, as well as for other valued suggestions he gave me while going over the British war hospitals for these diseases in the spring of 1918.

The treatment thus outlined has a number of advantages hitherto not included in the care of syphilis. Into its category can come the bulk of the early cases. Once it has been decided on for the patient, and, as I have observed, it is applicable in the great majority of cases, that patient is launched with a reliable ticket which should carry him safely to the end of his course.

The patient's satisfaction on being so securely carried along is no small part of his progress toward recovery; and the surgeon's obligation to see his patient through is immensely lightened by having so many steps decided at one stroke. In the collective care of these cases, which come along in classes of ten or a dozen each, the time saving is tremendous. The results so far with this plan of treatment have been entirely satisfactory. With this simple formula before us we are kept up to the observance of all the little but essential factors that go with the guidance and technical medicinal care of syphilitic infection.

STANDARD SYPHILIS NO. 1

A routine course of treatment for ordinary fresh cases of syphilis in otherwise healthy men (to be interrupted in the event of dermatitis, jaundice, or other signs of intolerance supervening).—Each patient to be carefully scrutinized for signs of stomatitis or general malaise, his weight to be taken, and his urine tested before each injection.

In conjunction with the employment of this course of treatment, each medical officer shall be familiar with "Proposed Modification of Circular No. 14, W. D., Office of the Surgeon-General."

Patients are to be treated at base hospital until open lesions are healed, when they will be sent to development battalion or regimental surgeon for completion of treatment.

The scheme of arsphenamin dosage is based on 150 pound men, or 1 decigram to about 30 pounds of body weight.

	Arsphenamin (Intravenously) Gm.	Mercuric Salicylate, 33 Per Cent. in Olive Oil (Intramuscularly) Grains
First day	0.3	1.0
Sixth day	0.4	1.0
Eleventh day	0.4	1.0
Eighteenth day	0.6	1.0
Twenty-fifth day	0.6	1.0
Thirty-second day	0.6	1.0
Thirty-ninth day	...	1.0
Forty-sixth day	...	1.5
Fifty-third day	...	1.5

One month rest, then take Wassermann; if positive, repeat entire course; if negative, repeat the mercury alone.

At the end of second course, rest two months; then take Wassermann, and give third course in accordance with rule for second course.

During second year, if Wassermann is positive repeat entire courses as above. If negative, give two mercury courses with four months between.

With this word of explanation as to the care of syphilis we will continue our rounds in Building Y. We first go into the ward for early cases of syphilis, before the lesions are healed or the skin eruptions have vanished, and then to the wards to which, in the course of treatment, they have been advanced, and where they are free from the obvious signs of infection (Fig. 8).

A sunny porch is set aside for patients with chancroids. Here are seen the patients with their sores exposed to the sun, which heals rapidly the majority thus infected, without much of other treatment save constant cleanliness. All patients with chancroids are kept constantly under observation for a syphilitic infection, and a surprisingly large number are found thus doubly infected. From here we visit the ward for skin cases and so finish our rounds in Building Y.

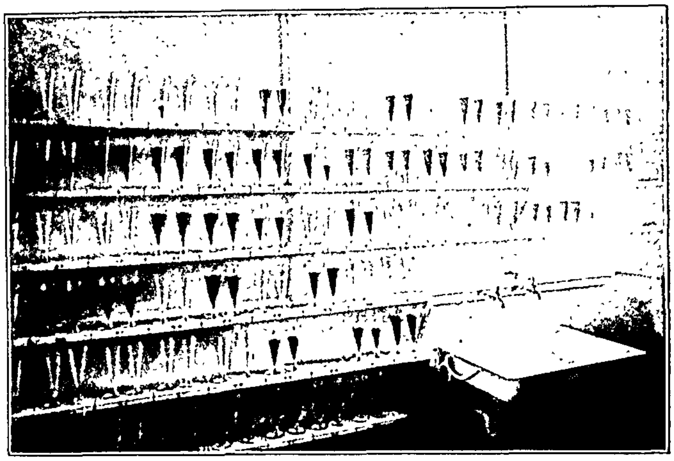

Fig. 9.—A wall of the two glass test room.

TREATMENT OF GONORRHEA

Next we go to Building Z, equipped for the care of gonococcus infections. Here it is we have set for ourselves a special task, and one which hitherto has had scant attention. With the chronic and complicated cases we carry out with care all of the well known and well tried modes of treatment that have gained for themselves some clean-cut claim to merit, and by these means remove, as far as possible, from these scarred and strictured and generally outraged tissues, the infection present. Resentful as the surgeon often becomes at this vast army of recurring chronics, these uncured and complicated cases which stumble on from one stage to another, it would hardly at present be fair to put these cases all down to the blunders of either medical misattention or blame the patients themselves, because no suitable standard for the successful care of the early infection has yet been set. So it is in these acute cases, in which the infection is freshly contracted,

Fig. 10.—Treatment trough.

that we have laid out for ourselves the special task to see what proportion of these patients it is possible to bring to a complete and early cure, before the gonococcus has invaded to any extent the urethral glands or follicles or extended back of the membranous urethra which guards the openings of the prostatic and seminal ducts.

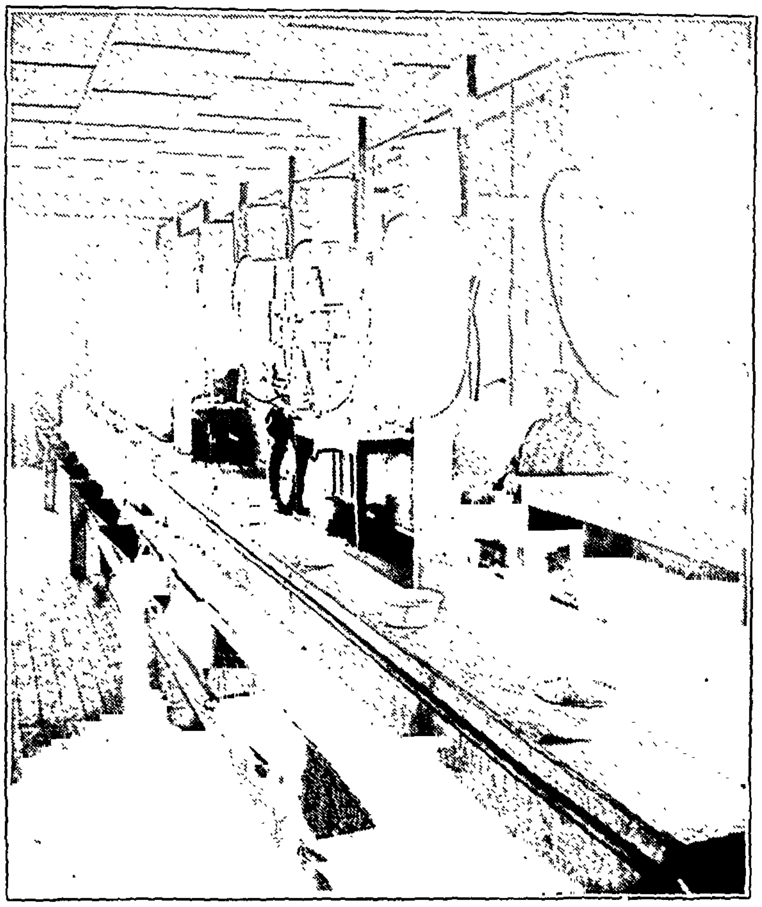

Fig. 11.—Treatment trough.

To this end a uniform treatment has been adopted which goes by the name of Standard Gonorrhea No. 1.

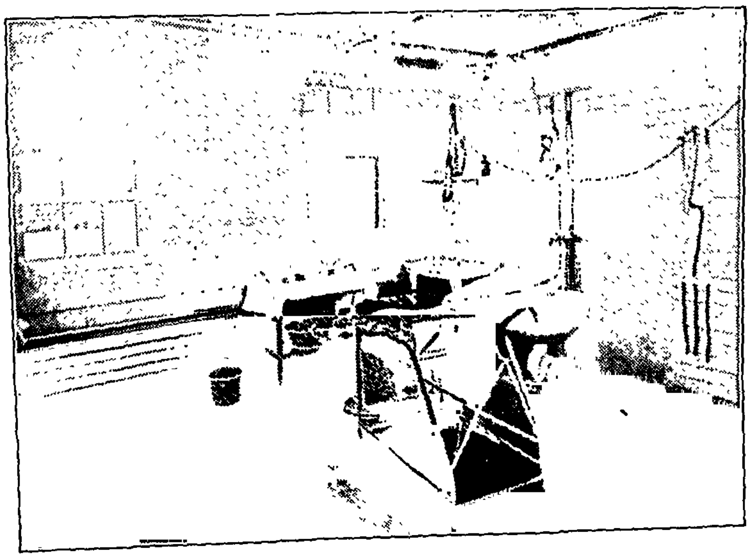

Fig. 15.—Cystoscopic room.

A brief study of this will show that it is nothing more than a succession of safe and simple steps—marked off into periods or phases. But only by thus standardizing some plan and carefully pursuing it is it possible to tell by what means the disease can most successfully be treated. To many medical men this plan will doubtless appear impracticable; but what they mean when they use that term is, probably, "inconvenient"; for none whose minds are capable of measuring the human cost incident to gonococcus infection can fail to know that a cure for this disease at any cost is cheap. The thing of immediate interest here, however, is the results obtained, and these results, so far as we have been able to follow our cases discharged as cured, are far beyond the expectation with which we began this experiment.

STANDARD GONORRHEA NO. 1

A routine course of treatment for ordinary, early and uncomplicated cases of gonorrhea in otherwise healthy men. Employed at base hospital and continued at development battalion or by regimental surgeon (to be interrupted in event of complications or intolerance).

DURING FIRST TWO WEEKS

In bed from four to eight days, then "up" if inflammation has subsided. Bland diet. Two glass test each morning with first urination. Smear on Monday and Thursday mornings, before urination. Sandalwood oil, 5 minims three times a day, after eating, and increase 5 minims daily until 15 minims three times a day, after eating; then decrease 5 minims daily. Irrigation twice daily (at 5 feet, patient standing) with potassium permanganate, 1:8,000, from 105 to 115 F. The irrigation not to be "through," i. e., into the bladder, until the patient can relax without the *slightest discomfort.* Hand injections to be used while infection remains anterior.

DURING SECOND TWO WEEKS

Bland diet continued. Patient should be up all day, and doing from two to four hours of light work. Two glass test and smear as before. Do not repeat Sandalwood oil course, if improvement is marked as it should be. Irrigation twice daily as before, with potassium permanganate solution, 1:6,000 at 6 feet, or injections if infection is still anterior.

DURING THIRD TWO WEEKS

Diet bland, but increased. Patient should be having from three to six hours daily of light work. Two glass test and smear as before. If any discharge or cloudiness of urine is present, potassium permanganate, 1:4,000, irrigation.

When free from symptoms (no discharge and clear urine) for two weeks without treatment, and doing from three to six hours' work daily, the patient in most cases may be considered fit for duty and infection free.

Note.—In seeking a useful basis of treatment for the ordinary run of gonorrheal cases, it can be easily understood that no lesson of value can be learned unless the plan laid down is followed accurately in every detail.

Each medical officer should keep himself familiar with the Little Red Book of treatment from the Surgeon-General.

RESULTS OF TREATMENT

The curative results of treatment in the first twenty-eight cases with Standard Gonorrhea No. 1 have been based on the following:

1. Before being taken off treatment: (*a*) no discharge; (*b*) urine clear; (*c*) gonococcus free, for a period of ten days.
2. With no treatment: with no restriction of activity; with no signs of disease, for two weeks.

The average time for cure, which includes the two weeks period of observation, has been from five to six weeks.

So far as we can tell, none of these patients have had a recurrence.

Of those who had had previous infections, in whose cases treatment was begun for a fresh infection (not recurrence) within the first two weeks, 66 per cent. were returned to duty cured, and 33 per cent. improved.

Of those who had had no previous infection, in whose cases treatment was begun during the second week of the disease, 80 per cent. were returned to duty cured, and 20 per cent. improved.

Of those who had had no previous infection, in whose cases treatment was begun during the first week of the disease, 90 per cent. were returned to duty cured, and 10 per cent. improved. In the last class, the percentage was drawn from twenty cases. The uncomfortable fatality of setting a new figure is the future obligation it sets on all time ahead to meet or pass it.

WARD Z

Base Hospital, Camp Logan, Texas

STEPS TO BE FOLLOWED IN USING THE TREATMENT TROUGH

Treatment hours, 6 a. m. and 2 p. m.

1. A list of the patients to be treated, with the treatment they are to receive, will be prepared before each treatment hour.
2. All sterilization, solutions and dressings will be ready for use at the treatment hours.
3. Patients will be called in groups up to the number of fifteen and in accord with the treatment they are to receive. Those who have "anterior injections" come first; those getting "through" irrigations come after.
4. When patients are lined up according to the list, they will proceed according to the following instructions:

(1) Disrobe.
(2) Remove soiled dressings.
(3) Urinate.
(4) Wash. Flush out urethra. Injections: Fill urethra and hold one m. Fill again and hold as above.
(5) Do not hurry. Irrigations: Flush out urethra. Fill bladder and evacuate. Fill bladder again and evacuate.
(6) Butterfly dressing.
(7) Dress up.
(8) Dismissed.

NOTE TO ATTENDING MEDICAL OFFICER

Each of the above steps to be carried out with precision. Each patient to be watched and guided where necessary. It is all important that patients are not hurried with their injections or irrigations, and that even the slightest pain is avoided in the treatment.

Major J. B. Clark, M. C.,
Chief of the Genito-Urinary Service.

EQUIPMENT

On continuing our rounds, the practical means and equipment used in this treatment will be seen. As noted on Standard Gonorrhea No. 1, it will be seen that the daily urine is studied by a two glass test of the *first* urination of the day. This is essential to successful treatment of gonococcus infection and is made simple by a room fitted for the purpose, a wall of which is shown in Figure 9. In this room, on Monday and Thursday mornings, smears are taken before the urination, in order to note the time the gonococcus disappears. Next we see the treatment room (Figs. 10, 11 and 12). Here it is possible to treat, collectively, fifteen patients with the same attention we might give to one, as a study of the injection and irrigation trough will show.

DETAILS OF TREATMENT

This equipment has been devised to insure accuracy in the matter of irrigations or injections, and to prevent the slightest possibility of injury to the patient. The standing position for irrigations is chosen because it is in this position that the male most readily relaxes the external urinary sphincter. The treatments are always carried out under the direction of a medical officer, who gives personal attention to each of the patients to see that they carry out properly the treatment, which has been taught them in small groups at the beginning of their care. It will be noted that all forms of treatment in this service are carried out by the medical officers; nothing is left to the chance care of attendants. The work has been so systematized that this is possible. The form that directs the trough treatment shows the manner in which it is carried out, and the lesson in cleanliness it conveys to the patient. After his dressing is collected by an orderly, he is directed to wash the hands and penis with the cotton ball placed in the bowl of mercuric chlorid in front of him. Each patient receives a freshly sterilized tip or syringe for his treatment, and is given a fresh dressing at the finish. The greatest watchfulness is at all times exercised to see that all patients are protected with these dressings. The time taken to treat each group is eight or ten minutes without the slightest hurry. To

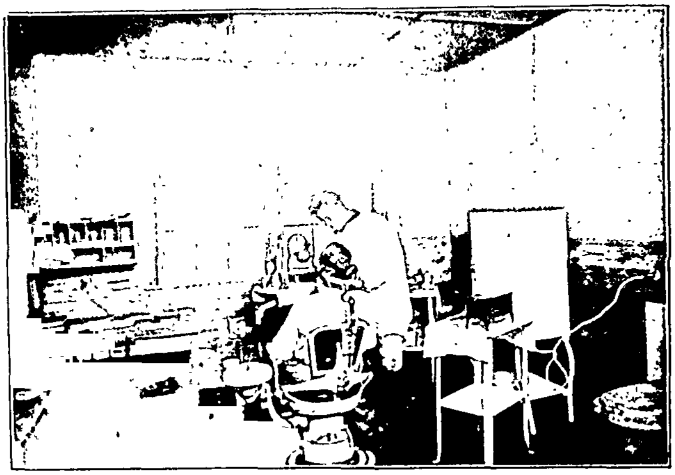

Fig. 16.—Dental operating room.

Fig. 17.—Class in graduated exercises.

proceed with our rounds in this building, we come first to the patients who are freshly infected and in bed.

Which elements of the four essential ones in this treatment are the most important it would be rather hard to say: (1) the rest in bed and bland diet; (2) the confidence sustained by an obviously intelligent attention; (3) the local treatment, or (4) the simple sandalwood oil medicine.

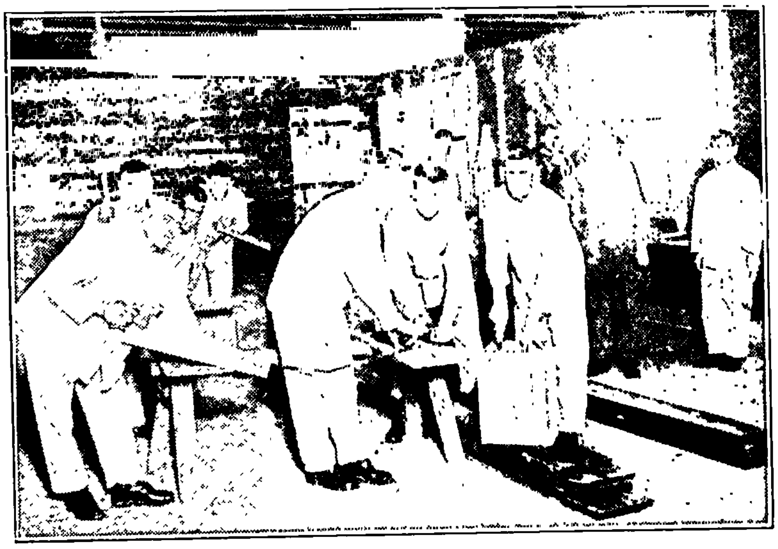

Fig. 18.—Class in carpentry.

These patients are from four to eight days in bed, the duration depending on the severity of the inflammation. They are carefully instructed as to the dangers of their disease, and our aim to give them a sure and speedy cure. When they are allowed to get up it is for two hours the first day, four hours the next, six hours the next, then all day, and they are promoted to the "up" patient ward. The progress sheet of the clinical record will show how their progress is noted and followed (Fig. 14).

Short History Past hist.neg. 5 days ago noticed sore on foreskin. Incubation 5 wks.

DIAGNOSIS Syphilis primary. Manifested by chancre.

Laboratory Spirochaetae pallidae - Positive by "dark field" 11-1-1918
Wassermann still negative 12 days after admission.

Condition on Admission (10-31 1918) Pea size ulcer of propuce. Slight ing. adenitis.

Progress Rapid improvement, ulcer entirely healed on 8th. day.

Treatment Standard Syphilis No.1. Begun day after admission,
Discontinued on 32nd. day of treatment.

Condition on Discharge (12-4 1918) No signs of disease except scar of chancre.

Number DAYS in hospital (34) Disposal Duty. Development Battalion.

Treatment advised Continuation of Standard Syphilis No.1. Case Incomplete

Note—These cards in duplicate. One for file. One with patient, to be filled on reverse and returned to Base Hospital when patient is discharged from treatment.

Fig. 19.—Record card, reflecting in a few words the entire activity of the genito-urinary service.

We then pass through the other wards where those in whom the disease is chronic and those who are crippled are installed—the harvest of other days and other ways of caring for this common malady, the very harvest we are trying out a means to minimize. Leaving Building Z and our medical officers there busy in the treatment room with the "chronics," we go to Building X, where we are watching the end-results of Standard Gonorrhea No. 1. The acutely infected are treated on the lower floor; the terminal treatment of the first course of Standard Syphilis No. 1 is given on the upper floor. Through the coming of the armistice, the facilities for carrying along treatment outside of the base hospital have been sufficiently curtailed to justify the keeping of our patients somewhat longer than would otherwise have been done. This has served well the purpose of putting our plans of treatment on a firmer footing, and incidentally we believe has promoted the interest of the government by giving these men their treatment under the best available conditions.

OUTLYING INTERESTS

In the afternoon we start out for a visit to our outlying interests that are a part of the service. The room for cystoscopy and pyelography (Fig. 15) is in the operating pavilion in connection with the roentgen-ray department. This proves by experience to be but a small part of the Army genito-urinary work.

Figure 16 illustrates an important phase of our service: that of a dentist devoting his entire time to sexual disease work. The equipment includes a steam sterilizing apparatus—a thing seldom seen in a dentist's operating outfit. Here, when the teeth of the syphilitic are treated, the work is done under scientific surgical precautions. With a dentist keeping the teeth of our patients in order, we have seen no signs of stomatitis or salivation. This work is preventive as well as restorative. Weekly lectures with tooth brush demonstrations are given in all the wards. The teeth of all new patients are immediately examined, and necessary cleaning and repairing attended to.

Next we visit one of our classes in physical exercises (Fig. 7). As soon as patients are able to take on this activity it is added to their daily regimen and graduated according to the case. Later are added classes in manual labor, such as carpenter work (Fig. 18).

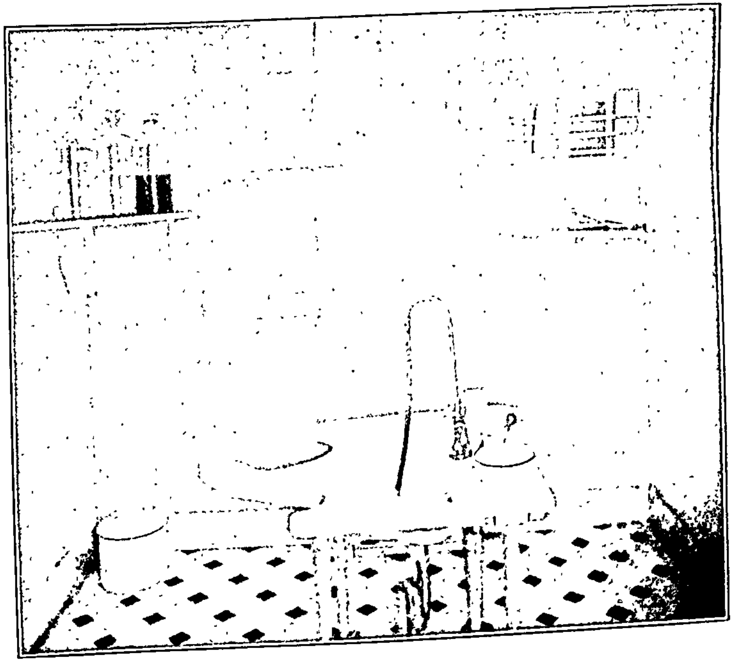

Fig. 20.—Model prophylaxis room.

These classes have the triple advantage of diversion, education and health-restoring activity. A final card record (Fig. 19) is made of all patients as they are discharged from the hospital. These cards in terse terms record the entire activity of the service, and from them statistics can be drawn, or studies for the improvement of our work can be made. They are made in duplicate so that a copy can be sent with the patient in case his treatment has not been completed at the hospital. In this way they serve as a follow-up system; for the card sent with the patient has the continuation of his treatment noted on its back, and when the case is complete the card is returned to go with its fellow in our file, thus bringing our record to a conclusion.

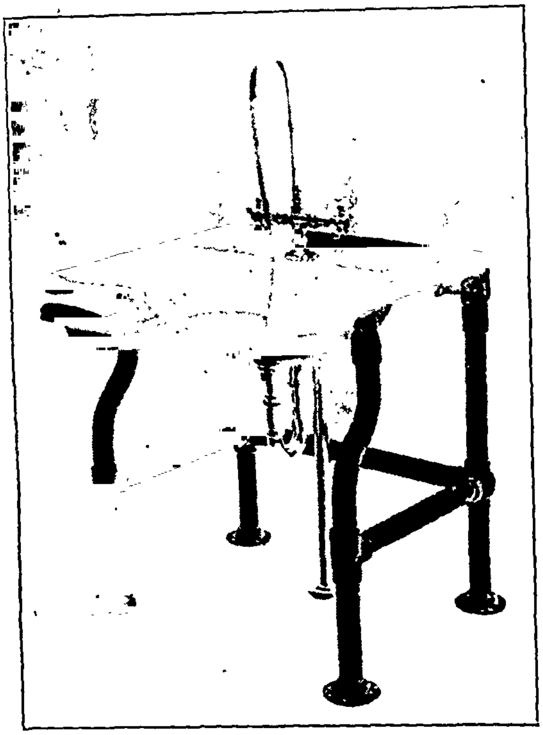

Fig. 21.—New straddle stand.

Last we visit the prophylaxis station for the detachment, but under the direction of the genito-urinary service. Here it is that we have attempted from the scientific standpoint to make a model prophylaxis room (Fig. 20), using the straddle stand (Figs. 21 and 22) as the operating center of the room and putting on two or three wall shelves all the simple equipment needed for this work. As this part of our work is being described in another article, it would be superfluous to make more than this mention, for the sake of completeness here.

CONCLUSION

In this paper an effort has been made to bring only those things into the foreground that are somewhat of a departure from the ordinary beaten track. It is regretted that they could not have been dealt with more in detail; but it has seemed best to show them from a bird's-eye view and thus get a rather more general impression of the whole as representing a systematic scheme for this department of medicine.

John Hunter's Ideas About Gunshot Wounds.—Hunter was the first clearly to appreciate and teach that in the gunshot wounds of his time "a part of the solids surrounding a wound is deadened . . . and is afterward thrown off as a slough which prevents such wounds healing by the first intention." He pointed out how the separation of a slough might open a part of a large artery or a portion of intestine. He realized that "the greater the velocity of the bullet the cleaner it wounds the (soft) parts." He noticed that "when the velocity is small the direction of the wound produced by the ball will, in common, not be so straight, therefore its direction not so readily ascertained, arising from the easy turn of the ball."—Sir Anthony Bowlby, *British Medical Journal.*

MYASTHENIA GRAVIS

WITH REPORT OF A CASE *

CHARLES ROSENHECK, M.D.
Neurologist, Hospital for Deformities and Joint Diseases; Instructor in Neurology, Columbia University College of Physicians and Surgeons
NEW YORK

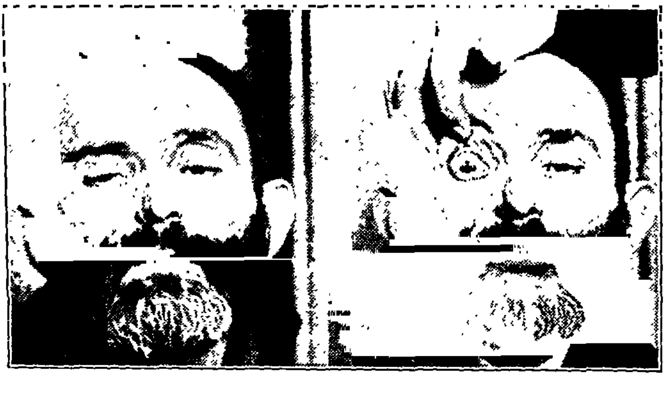
In order to appreciate the clinical picture of this remarkable affection, it seems appropriate to preface the description of the case with a definition of myasthenia gravis. This affection is characterized by McCarthy as "a disease with fatigue symptoms referable to the muscular system due to an exhausted condition of nervous enervation without definite pathology in the nervous system and with minor changes (lymphocytic infiltration) in the muscles."

To Wilkes belongs the credit of first accurately describing this disease. Subsequently Erb, Oppenheim, Eisenlohr, Bernhardt, Strümpell, Campbell and Bramwell, in a series of articles and reports of cases, definitely established the clinical entity of the malady. Goldflam's contention that the disease is not immediately fatal and may be subject to marked remissions over a lengthy period is borne out by our patient, whose history dates back nearly five years.

The relation of the disease to the endocrine disturbances, while not conclusive, is at least highly suggestive; for there is increasing evidence that a dysfunction of the glands of internal secretion plays a considerable rôle in the myopathic affections.

REPORT OF CASE

History.—A man, aged 48, born in Russia, a teacher of Hebrew, complained of double vision, bilateral weakness of upper and lower extremities, and inability to masticate food for any continuous time, or to carry on a lengthy conversation. Early fatigue accompanied every voluntary effort, whether walking, manual activity, the eating of food or the effort of speech. He was quite sure as to the time of the onset, which dated back nearly five years. At that time, as he expressed it, he left his home in his usual good health, and after proceeding a short distance he suddenly crumpled up on the sidewalk. Loss of voluntary power was present to such a degree that some passing strangers had practically to carry him to his home. He was put to bed, where after a short rest he regained considerable strength and motor activity. A day or two, however, after arising, he found that



Oculomotor exhaustion after looking at a fixed spot for a considerable period, and raising of ptosed lid, which patient is unable to do voluntarily after period of oculomotor exhaustion.

---

* From the Service of Dr. Henry W. Frauenthal, Hospital for Deformities and Joint Diseases. Patient presented to the Clinical Society, Feb. 11, 1919, and to the Harlem Medical Society, March 11, 1919.

he was unable to dress or undress himself. His eyelids, which were apparently in proper position at the start of the day, assumed a drooping, ptosed position as the day advanced. Often the ptosis was so complete that in order to see he had to elevate the drooping eyelids with his fingers. He was unable to follow his vocation, because in pronouncing the benediction or prayers during a ceremonial, his voice, which at first seemed quite strong and resonant, gradually assumed a nasal character and then was completely lost. After a short rest he was again able to resume. This state of affairs caused him considerable embarrassment and humiliation and forced him to abandon his calling.

In masticating his food, the conduct of the masseters and temporal muscles varied. At times he was able to finish his meals without incident. At other times after several chewing efforts his jaws relaxed and apparently lost their power. After a variable rest he was able to resume, only to have the same loss of voluntary power recur.

In the act of walking, similar conduct on the part of his motor control was manifest. He often fell, and showed numerous cuts and bruises as a result of these unheralded prostrations to the ground. He was quite sure that his symptoms were not progressing. On the contrary, he thought that he was improving slightly. In the patient's own words, all of his initial symptoms were present, but they varied from day to day. On rare occasions the discomfort of all the symptoms of the malady held full sway. He complained of no pain, slept well, had a good appetite, and had no cardiac, renal, pulmonary, vesical nor visceral disturbances.

His habits were good. He was a moderate smoker, and drank occasionally. His previous history gave no clue to the development of the malady. He insisted that he had always enjoyed good health, and he did not recall any acute illness

His family history was also barren of information. His mother died of cerebral hemorrhage. A brother died suddenly at the age of 24, following an operation for some intracranial disturbance.

Examination.—There were no abnormal attitudes of the voluntary motor system noted, with the possible exception of the tilting of the head backward so as to enable the patient to overcome his visual difficulties resulting from the ptosis of the eyelids. No deformities were noted. The gait was normal: all the phases of pelvic, thigh, leg and foot motion were normally performed in sequence. All types of coordinative effort—both of equilibratory and nonequilibratory type were normally performed. No dysmetria was noted. All rapidly repeated pronation and supination movements were normally performed. All skilled test acts were performed in a satisfactory manner. There were no tremors, twitchings, choreiform movements, athetosis nor spasms.

Examination of the deep reflexes revealed moderate hyperreflexia of the jaw muscles, pectorals, biceps, triceps, radial, ulnar, suprapatellar, patellar, Achilles tendon and periosteal. Equality in reflex action was present on both sides. Of the superficial reflexes, the ciliospinal, supra-umbilical, suprapubic, upper and lower lateral abdominal and cremasteric reflexes were equal and present on both sides. No pathologic reflexes, such as the Babinski, Gordon, Schaefer, Oppenheim or Chaddock, were in evidence.

Decided impairment in muscle strength was noted in the entire somatic musculature. This embraced all possible forms of muscular effort, such as flexion, extension, rotation, abduction and adduction. No atrophy nor hypertrophy of the muscles was noted. Hypotonia or hypertonia was absent.

Rapid exhaustion of faradic irritability was in evidence, and was particularly marked in the muscles of the shoulder girdle and the muscles of the thigh. Thus we have the myasthenic reaction of Jolly, which is pathognomonic of this affection.

No abnormal associated movements were noted.

General sensory examination revealed acuity, localization and discrimination normal for touch, pain, temperature, pressure and muscle-tendon sense. Stereognosis and barognosis tests were performed in a satisfactory manner.

Marked weakness was noted in the muscles of the oculomotor apparatus (third, fourth and sixth). Weakness of the motor portion of the fifth nerve was present. Facial innervation was slightly impaired. All other cranial nerves were intact and performed their functions in a normal manner.

The mental status was apparently normal.

Systemic and laboratory examinations detected no noteworthy abnormalities.

CONCLUSIONS

The diagnosis of myasthenia gravis seems perfectly obvious and justifiable when in retrospect we consider the onset and the peculiar vagaries on the part of the voluntary motor system when they were called on for any type of continuous effort. Surely no affection either of the upper or the lower motor neurons is capable of producing such a clinical picture. Were neurons actually involved, we should be confronted by clinical features of a chronic progressive character, paralytic in type, involving the nuclei in the bulb or the cells in the ventral horns. Reflex changes and alterations in electrical behavior different from those we have observed would be present. On the contrary, we have noted the transitory character of the paralysis, present only after continuous effort and always disappearing after the effort has been expended and the muscles have had time to recuperate. The peculiar electrical phenomena, alien to any affections of the neural axis per se, put a final stamp on the diagnosis.

Note.—Since this report was written, a case referred to me by Dr. M. J. Mandelbaum for double ophthalmoplegia proved to be one of myasthenia gravis. The oculomotor disturbance has lasted for five years and is the only symptom present. Goldflam has called attention to this in his writings. The myasthenic reaction is present, but all other neurologic data are uniformly negative.

370 Central Park West.

MODEL BARRACK FOR PREVENTION OF RESPIRATORY DISEASES IN THE ARMY

F. T. WOODBURY, M.D.
Colonel, M. C., U. S. Army
CAMP GORDON, ATLANTA, GA.

A study of the sick rate in camps and cantonments shows that the greatest morbidity and mortality have come from the respiratory infections, and it is undoubted that they are favored by crowding in poorly ventilated dormitories or squad rooms, which reduces resistance and directly favors irritative laryngeal and nasal reflexes whereby coughing and sneezing are promoted, which in turn spread the infection. When the opposite conditions are maintained, when men have plenty of fresh air and are separated, these diseases immediately decrease. As at present designed and administered, the army squad room will be held directly responsible for our present morbidity and mortality statistics, because it is usually a combination sleeping and lounging room. It is usually overcrowded, and at night is filled with vitiated atmosphere still further polluted and affected with men with irritative coughs.

The ventilation of the squad room, no matter what type of ventilation is installed, invariably depends on the pleasure of the occupants, since windows are opened and closed by individual preference, notwithstanding existing orders to the contrary, especially in cold weather and when winds are blowing.

The warmth of the squad room depends on a number of factors; the construction of the building itself may be faulty, allowing drafts and leakage of cold air from unexpected quarters; the heating system may be inadequate for the use of the building or faulty in application, and it depends finally on the faithfulness of some individual stoker. As a result of this combination of circumstances, the squad room is in reality an excellent incubator for the cross-infection of respiratory diseases.

Hitherto the number of occupants in a squad room has been based on the number of square feet in the floor or cubic feet in the room, which, in my opinion, is a faulty standard, as the conditions sought to be obtained are fresh air, plus warmth, minus crowding, which result is nullified by the circumstances mentioned above.

The ideal sleeping quarters are those wherein the person gets a maximum of fresh air and is sufficiently removed from other persons or protected by screening as to prevent cross-infection. A bivouac with one man to a shelter tent would be the ideal situation.

In seeking to attain fresh air, the popular objection is immediately made that the sleepers will take cold. This is a matter which can be regulated by proper clothing, which includes a nightcap or knitted wool helmet. The objection, therefore, is not valid.

A MODEL BARRACK

I present herewith some plans for a model barrack for a company. The sanitary features are:

(*a*) The sleeping room is divorced from the lounging room, whereby the sleeping room is occupied only during the sleeping hours by the sleepers.

(*b*) There is a *cloth window* at the head of each bed whereby each sleeper will receive fresh air continually without drafts.

(*c*) Each sleeper will be screened from other sleepers so as to cut off the chances of cross-infection by a solid cough screen of beaver board and a curtain.

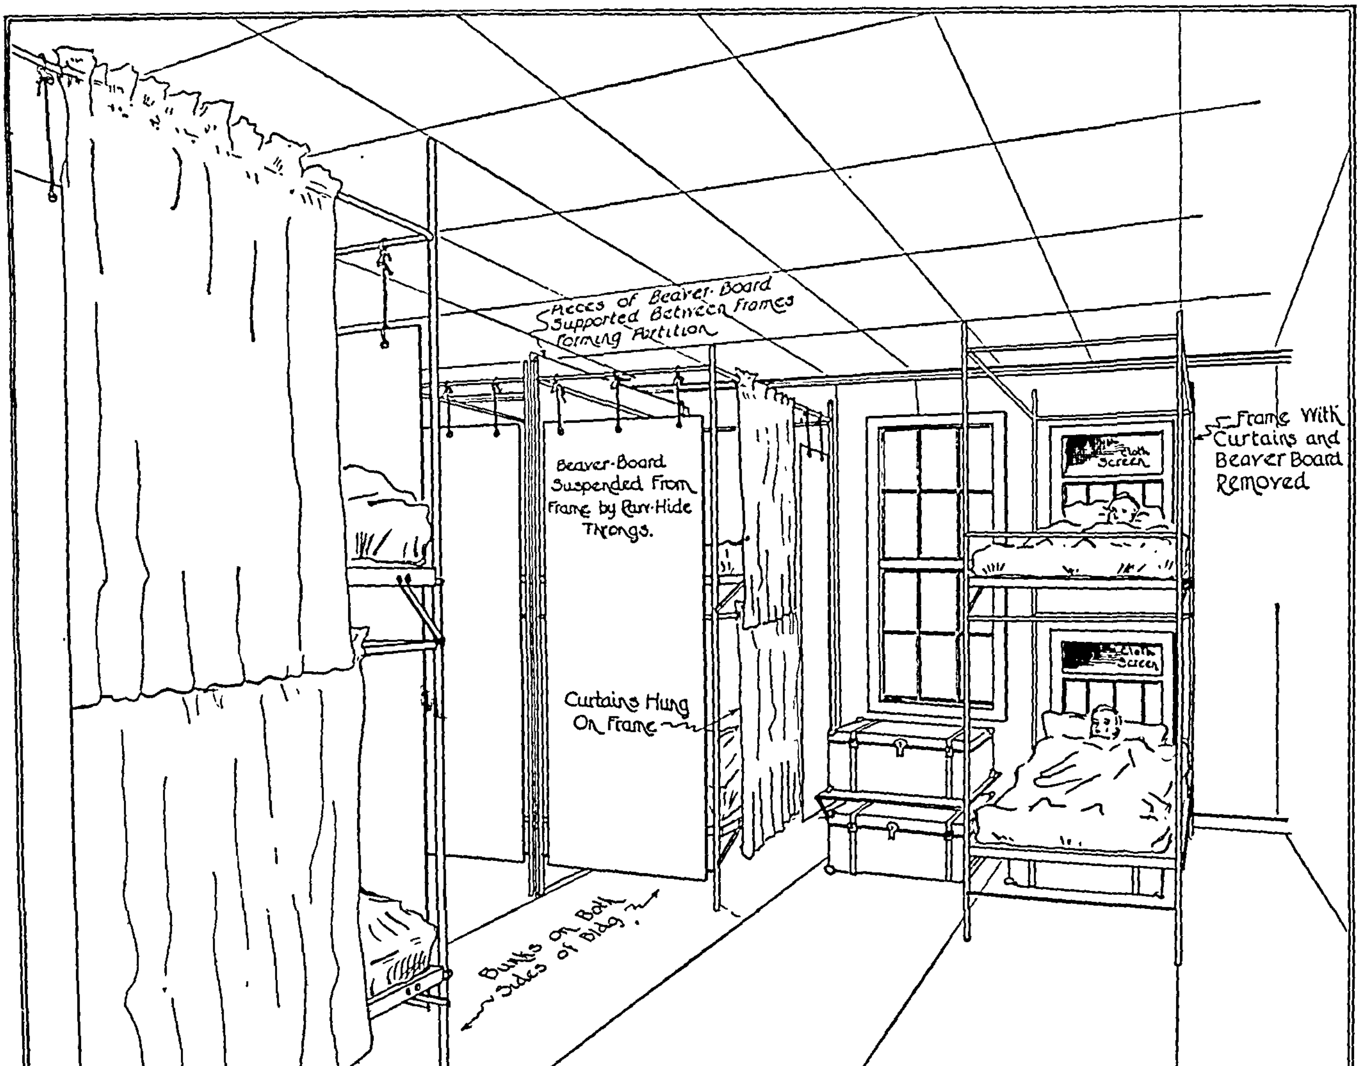
(*d*) In case an infectious disease arises, only three contacts need to be isolated.

(*e*) In warm weather the partitions at the foot of the beds may be removed, if this seems desirable, without nullifying the objects of the design, and the windows may be opened.

(*f*) All partitions, being made of beaver board, can readily be removed or replaced, and may be painted or burned in case of vermin.

(*g*) All beds can be readily removed and the entire room scrubbed or painted.

(*h*) This room may or may not be heated by steam pipes running low along the walls.



Pieces of Beaver-Board Supported Between Frames forming Partition
Beaver-Board Suspended From Frame by Raw-Hide Thongs.
Curtains Hung On Frame
Bunks on Both Sides of Bldg.
Frame With Curtains and Beaver Board Removed
Cloth Screen
Cloth Screen

Arrangement of bunks for sanitary purposes.

(*i*) The curtains can be made of any cheap washable material and are individual for each sleeper.

The special features of the barrack necessitated by the dormitory features are:

(*a*) A special dressing room for each dormitory, which may be heated, and attached to the dormitory so that the men do not have to go outdoors to get to the baths and latrines. This is an especially bad feature of present cantonment construction.

(*b*) A recreation room ample and separated from the dormitories.

TONSILLECTOMY IN MYOSITIS AND ARTHRITIS

RESULTS IN TWO HUNDRED CONSECUTIVE CASES *

H. I. LILLIE, M.D.
AND
H. R. LYONS, M.D.
ROCHESTER, MINN.

That the tonsil is a focus of infection in cases of myositis and arthritis is common knowledge and will not be discussed in this report, which deals with the results of operation in a series of consecutive cases of myositis and arthritis.

As a preliminary to the selection of the 200 cases of the series, letters of inquiry were sent to 400 patients who had been operated on consecutively. The answers from the first 200 were accepted as sufficient data for the basis of our report.

The data recorded were facts concerning sex, age, first attack of myositis or arthritis, number of attacks, joints involved, presence of pyorrhea alveolaris or tooth abscess, history of tonsillitis, history of previous tonsil operations, and the present condition, whether ambulatory, incapacited or invalided.

In recording the improvement in the long standing cases we fully appreciate the importance of the time element, and also the fact that in many other cases patients may improve without treatment. The series includes, however, all types of cases, from the very mild myositis to the very severe deforming arthritis that is strictly of an infectious origin. The gonorrheal and syphilitic types, etc., are excluded.

DISCUSSION OF TWO HUNDRED CONSECUTIVE CASES

All of the 200 patients in the series were operated on between July 1, 1917, and Dec. 31, 1917. Letters of inquiry with regard to the final results were sent in November, 1918; thus ample time was given for improvement, although undoubtedly in a few cases there would have been further improvement had more time elapsed. Our percentages are, therefore, from this standpoint alone, too low rather than too high.

Eighty-seven of the patients were aged 30 years or less, and 113 were aged 31 years or more. The average age was 30 years. Seventy-one (81.6 per cent.) of the first group of eighty-seven patients were better after tonsillectomy; the others were not improved. Eighty-eight (77.7 per cent.) of the second group of 113 patients were better after tonsillectomy; the others were not improved. These percentages indicate that as the condition becomes more chronic less benefit is derived from tonsillectomy, although in the long standing cases improvement is found almost as often as in the recent or subacute cases.

The average age of the patients who reported their condition worse was 40 years. The duration of the myositis or arthritis in all the cases varied from a few days to thirty-nine years. The average duration of the myositis or arthritis in patients improved by tonsillectomy was eight years.

The ten patients in whom the condition was chronic and who were invalids at the time of operation report results as follows: Two patients who were confined to bed were the same after tonsillectomy. Four walked but were incapacited for work; ultimately two of these were better. Two were wheel-chair cases; one was better and one the same. Two had had to use crutches; one was better and one was not improved. Thus four of the ten patients (40 per cent.) reported improvement.

In the cases of arthritis, the joints involved in the order of frequency were the knees, the hands, the ankles and the hips. In the cases of myositis, the shoulders and arms, the back, the lower extremities and the neck were involved.

In the cases of pyorrhea alveolaris or tooth abscess, demonstrated both clinically and by the roentgen ray, 81.4 per cent. of the patients were better after tonsillectomy; 36 per cent. of these had dental work done in addition to tonsillectomy, and 45.4 per cent. had no dental work done; 18.6 per cent. of the patients were the same after tonsillectomy; 12 per cent. of these had dental work done in addition to tonsillectomy, and 6.6 per cent. had no dental work done.

PERIOD OF ONSET OF DISEASE

Years (Inclusive)	No.	Per Cent.
Between 1915 and 1917	79	49.6
Between 1910 and 1914	33	20.9
Between 1900 and 1909	37	23.2
Between 1890 and 1899	7	4.4
Between 1879 and 1899	3	1.8

It will be noted that in a considerable percentage of the cases in which a diagnosis of pyorrhea alveolaris, dental abscess or caries was established, the dental sepsis had been disregarded, and it is fair to assume that even a larger percentage of the patients had a possible focus of infection in their teeth and needed dental care. Too much emphasis cannot be placed on the importance of the care of the teeth as an aid to the cure in these cases. When patients who are examined by us present definite, marked dental sepsis and septic tonsils, we insist on having the teeth properly cared for before tonsillectomy is done.

The size of a tonsil is of variable importance in advising tonsillectomy. In the Mayo Clinic, reports and advice regarding tonsils are based on three main factors: (1) the result of properly expressing tonsillar crypts with a tonsil explorer; (2) the tonsil history, and (3) the patient's symptoms. The size of a tonsil is estimated on a scale of 1 to 4; 1 represents the submerged tonsil, 2 the tonsil that is just visible, 3 the tonsil presenting in front of the tonsillar pillars, and 4 the very large obstructing and pendulous tonsil. In the present series the average size was 2, those just visible in the cursory examination of the throat. This is the type that many physicians, specialists as well as internists, look on as harmless, and accordingly advise against a tonsillectomy. As a matter of fact, the importance of the tonsil as a focus of infection does not increase with its size, nor has it any relation to it. In our cases the tonsillar crypts were carefully examined and an exact history taken both of the throat and of the general complaint before advice was given as to the probability of the tonsils being the focus of infection. A conservative position was taken in every case. In 6 per cent. of the 200 cases a tonsillectomy had been attempted elsewhere, and in each case the myositis or arthritis continued as before, thus showing the value of a clean tonsillectomy in all cases.

---

* From the Section of Otology, Laryngology and Rhinology, Mayo Clinic.

One hundred and fifty-four of the 200 patients were unable to work, or at least were unable to work steadily at the time of their examination. After tonsillectomy, 118 (77 per cent.) of these were able to work steadily; thirty-five (22 per cent.) were the same postoperatively. Thirty-five patients of the series needed the help of crutches or a cane. Twenty-five (71 per cent.) of these were enabled by the tonsillectomy to discard any help; ten (29 per cent.) were not benefited.

Opinions have varied with regard to the end-result in cases in which an immediate reaction was experienced after a tonsillectomy because of an acute attack of myositis or arthritis. Twenty-four (12 per cent.) of the patients reported an acute exacerbation of their condition immediately after the tonsillectomy. Nineteen (79.1 per cent.) of these reported ultimate improvement; five were not improved. It is also noteworthy that of 159 patients who reported that they were better, eighty-seven (55.3 per cent.) reported that their improvement started immediately after the tonsillectomy; the average length of time before improvement began was eight weeks.

Ninety-two of the 200 patients had enlarged joints. Of these, fifty (54.3 per cent.) reported that their joints had returned to normal size after tonsillectomy, and 45.7 per cent. reported that their joints had remained the same. However, in a number of cases of long standing chronic arthritis with enlargement of the joints, the immediate results of a tonsillectomy have been surprisingly good. In many instances of long standing painful and enlarged joints, the joints have immediately decreased in size and become useful. We have had a number of patients who went to the hospital for operation using crutches or a cane, who were able to discard them thirty-six hours later.

Thirty-three of the patients had had treatment other than tonsillectomy, for example, massage, baths, electric vibration, phylacogens and osteopathy.

In the entire series only 57.7 per cent. of the patients gave a history of tonsillitis. This is of interest in view of the fact that many practitioners believe tonsillectomy should be advised only when there is a history of tonsillitis or quinsy. In addition to the patients who did not give a history of tonsillitis are those who did not have a tonsillitis followed by an acute arthritic attack. It is obvious, therefore, that a tonsil need not be periodically inflamed in order to become a focus of infection, and it is even less necessary that an attack of tonsillitis should immediately precede the acute attack of arthritis.

The foregoing data constitute the general findings in the patients who present themselves for examination. The cases vary from the very mild up through each succeeding grade of severity to chronic arthritis and invalidism. The average of the sum total, therefore, represents the results obtained in all cases.

TWENTY-EIGHT SELECTED CASES

A special study was made of twenty-eight selected patients who had a most severe form of chronic infective arthritis with marked involvement of the joints. In some of these, definite roentgen-ray findings were noted. The postoperative time element is identical with those of the other cases in the series. The average age of the patients was 37 years; the duration of arthritis was from ten months to eight years; the average duration of arthritis in those who were improved was eight years; the duration in those who remained unimproved was from eight months to twelve years. Sixteen (56.1 per cent.) reported their condition better, and twelve (42.9 per cent.) were not improved. Seventeen of the patients were aged 31 years or more, of whom nine (53 per cent.) were better postoperatively, and eight (46.3 per cent.) were not improved. Eleven were aged 30 years or younger, of whom eight (72.7 per cent.) were better after operation, and four (36.3 per cent.) were not benefited. The size of the tonsil was 2 in all but six of the cases.

It may again be noted that most of the patients in the series of 200 cases who did not obtain relief from tonsillectomy fall into the group of the long standing, chronic cases, and that in cases in which the arthritis was not improved after operation, six times as many of the patients were of 31 years or more as were of 30 years or less. Even in the group of the severe type of arthritis, 53 per cent. were of the older patients. Seventy-two and seven-tenths per cent. of the younger patients in the group were markedly improved.

Twenty-one of the twenty-eight patients were disabled or unable to work at the time of examination. Eleven (52.3 per cent.) of these reported that their condition was improved and that they were able to work; the other 47.7 per cent. were still incapacitated. Five (31.2 per cent.) of the eleven who were improved reported that their improvement started immediately following the tonsillectomy. The average length of time before improvement was noticed was three months. In order to determine more exactly the results obtained in these twenty-eight cases, they were classified into four groups:

Group 1. The mild type of cases in which there was a history of repeated joint enlargement that receded, and the patient reported for examination in the interval stage.

Group 2. Cases in which there was definite joint enlargement with the accompanying symptoms and signs, but without joint changes noted by the roentgen ray.

Group 3. Cases in which there was marked joint involvement of a chronic nature, and slight roentgen-ray findings, such as fibrosis of the joint capsule, or a beginning thickening of the bone on the articular surfaces.

Group 4. Cases in which there was not only marked and long standing joint enlargement but also in which the roentgen ray showed definite signs, such as marked increase in bone on the articular surfaces, typical spinelike processes on the vertebral articular surfaces, or the destruction or osteoporosis of the articular borders.

Twenty-two of the twenty-eight patients had enlarged joints before tonsillectomy was performed. Of this number, six (27.2 per cent.) reported that their joints had returned to normal size; the others reported no change. Four of these cases fall into Group 1 and two into Group 2. It is a striking fact that in the patients who had been practically invalids with chronic arthritis, and in whom no changes were found by the roentgen ray, the joints returned to normal size and function in a relatively short time, and conversely that the patients in Groups 3 and 4 had no beneficial change in the joint involvement. This distinction of type is paramount when the end-results are considered in detail. It should be remembered that it is the patients classified in the first two groups who are given a practically hopeless prognosis and little or no chance for improvement by most physicians.

Six (21.4 per cent.) of the twenty-eight patients reported an acute exacerbation of the joint signs and symptoms immediately following tonsillectomy. Three of these eventually reported improvement; the others were not improved. An acute flare-up or exacerbation postoperatively may be hailed as a sign that the tonsils were the active focus of infection. The end-results in these severe types of arthritis may not be entirely encouraging to the patient. Eleven (39 per cent.) had some form of dental work done in addition to their tonsillectomy. Nine (81.1 per cent.) reported their condition better; two were not improved. It may be assumed that many of these patients retain teeth that are acting as a focus of infection, and that a higher percentage of improvement would undoubtedly be reported if the roentgen ray were employed, and a careful examination were made in every case, so that all dental sepsis might be removed promptly and thoroughly.

SUMMARY

1. It is justifiable to advise a tonsillectomy in every frank case of myositis or arthritis.

2. A marked improvement may be assured from tonsillectomy alone in 79 per cent. of all cases.

3. It is necessary to remove all possibility of dental sepsis; by so doing a larger percentage of patients will be improved.

4. The duration of the myositis or arthritis is a factor in the ultimate results, although benefit and even complete cure is obtained in some long standing, chronic cases.

5. Forty per cent. of the patients with chronic myositis or arthritis who are invalids will respond favorably to tonsillectomy.

6. The size of a tonsil has no bearing on its possibility as a focus of infection. A careful expression of the tonsillar crypts and a history of throat trouble associated or not associated with the myositis or arthritis is essential in the diagnosis.

7. An absence of a history of diseased tonsil in no way eliminates the organ as a focus of infection.

8. A clean tonsillectomy, with the removal of the plica tonsillaris, is necessary in every case.

Report of Commission on Mental Diseases.—The Second Annual Report of the Massachusetts Commission on Mental Diseases, for the year 1917, shows that the total number of persons cared for by the eighteen or more public institutions of the state, the almshouses and private institutions, was 19,000. Of this number 80 per cent. were insane, 15 per cent. feebleminded, and 4 per cent. epileptic. The work in the state hospitals was somewhat handicapped during the year by the absence of many physicians in military service. The Massachusetts Committee for War Work in Neurology and Psychiatry was organized during the year, and cooperated with the war work committee of the National Committee for Mental Hygiene. A uniform curriculum in all the training schools for nurses was instituted, and the committee adopted a new form of reporting statistics recommended by the American Medico-Psychological Association.

INJECTION OF HOT SODIUM CHLORID SOLUTION IN TREATMENT OF VARICOSE VEINS

F. W. KAPPELMAN, M.D.
MILWAUKEE

I realize fully the responsibility of applying a new surgical method to the treatment of a given malady, particularly when such a method is entirely unsupported by any authority in medical history, so far as I have been able to learn; and also in view of the fact that I received no encouragement at the outset from those of the medical profession whom I deemed some of the best authorities on surgery in the city, and to whom I appealed for suggestions. Their answers were like this: "Your patient will possibly wake up dead with a lung embolism," or "You will most likely get a muscle sloughing," or "The solution will cool too much in passing through the tube to accomplish the desired result." Another looked at me and asked where I got the idea. When I told him it was my own, he turned on his heel, and with a look of dismay and a wave of his hand said, "You can't try it on me." A pathologist stated as a fact that the veins would regenerate. Such consolation reminds me of that part of the comic sheet in one of our daily papers entitled, "It's a great life if you don't weaken." All this, while not encouraging, was very helpful. The submission of these possible objectionable features was valuable, in that it gave me food for thought, and better enabled me to fortify myself in my technic against serious consequences.

After having completed my technic theoretically, I was confident that the operation would prove to be far superior to the old methods, if given a fair trial. That it is superior, I am now convinced beyond a doubt. While my experience with this operation is limited to seven cases, the results have been agreeably satisfactory.

The object of the operation is to obliterate the lumen of the vessels in situ by destroying the intima and causing complete atresia of the vein. Of course, there were problems to be solved, the most important of which were: (1) the minimum temperature of the solution which would produce the desired results; (2) how to keep the blood out of the vessels while the solution is being introduced, and (3) how to prevent embolism. From the first, each of these problems has been met successfully in the administration of my technic, with the exception of the temperature of the solution. This phase I had to experiment with on the patient because there was no other way in which it could be ascertained. Therefore, eager to have it a success, I used the solution at boiling point in my first operation. This caused a complete destruction not only of the intima, media and adventitia, but also of all the surrounding tissue and skin as well. Thanks to my foresight in selecting my case, a man who was suffering from only a small tuft of varicosities on the calf, this sloughing, although in itself not a pleasant experience, caused no ill effects. While this result was anything but ideal, it was gratifying because it disproved the assertion that I could not introduce the solution into the vein hot enough to accomplish its purpose. In my next two cases I used the solution at 185 F. In both instances the results were good, with the exception of sloughing at a small point in each, which was evidence that the solution was still too hot. Since that time I have used it at 165 F. with a perfect result in each case.

TECHNIC

The necessary equipment for the operation besides the usual knife, hemostats, stripper, etc., are: (1) an irrigator equipped with a 6 foot rubber tube having a small cannula in the end; (2) thermometer which will register boiling point, passed through a cork to suspend in the solution; (3) two sterile race horse bandages, and (4) a tourniquet.

The patient is prepared in the usual way and anesthetized. Assuming that it is the internal saphenous which is involved, it is located near the saphenous opening of the fascia lata and is divided between two forceps. A transfixed ligature is applied to the proximal end, which is allowed to retract. The vein is then stripped to a point even with the upper margin of the internal condyle of the femur. A small longitudinal incision is made over the eye of the stripper, which is forced through the opening. The vein is then grasped distal to the stripper, which is then withdrawn. The vein is pulled through the lower incision and cut off about 2 inches from the wound. The upper wound is then sutured and a dry dressing applied, held by adhesive strips.

The leg is then elevated. The blood, usually a small amount in the superficial veins, is expelled through the opening at the knee, and the veins are collapsed by means of the race horse bandage, which is wound very tightly around the leg from the ankle to just below the knee. Now a tourniquet is applied to the thigh to shut off circulation entirely. This leaves the deep vessels, both veins and arteries, filled, which prevents the solution from passing into and doing injury to the deep veins through the collaterals. The leg is now lowered to the table.

The 3 per cent. solution of sodium chlorid, now in the irrigator, which is elevated about 3 feet above the field of operation, is allowed to run into a receptacle until the tube and cannula are hot. It is then shut off and the cannula is introduced into the vein and is held in position by catgut tied around the vein and the cannula. This prevents the solution from escaping. At this point it is necessary for the assistant to exert pressure with the thumb over the external saphenous in the popliteal space while the solution is under pressure. This prevents the solution from passing through the communicating veins and the external saphenous into the popliteal vein. The solution is allowed to flow and the bandage is slowly unwound from the knee to the ankle. This permits the solution to flow into the empty vein from above, while the bandage prevents the blood from flowing in from below. As soon as the bandage is entirely removed, the flow of the solution is shut off and the cannula is removed. The bandage is then again applied as before, forcing the solution out and collapsing the veins. The tourniquet is removed. The vein is pulled taut and ligated as near the wound as possible, cut and allowed to retract. The wound is sutured, one stitch usually being sufficient, and a small dry dressing applied to the wound by means of adhesive strips.

Cases in which the external saphenous is affected require no stripping; in other respects the procedure is identical. When both saphenous veins are involved, the internal saphenous should be treated first.

ADVANTAGES OF THE METHOD

The points in favor of this operation over all other methods are:

1. The operation requires only a few minutes; hence a short anesthesia.
2. It is less tedious.
3. It is as easily accomplished in the presence of a large amount of panniculus adiposus as in its absence.
4. It involves a minimum amount of cutting.
5. It is cosmetically ideal.
6. The nerves are left intact; there is no dead sensation.
7. The lymphatics are preserved.
8. There is absolutely no pain after the operation.
9. The length of stay in the hospital is reduced to a few days.

Since writing this paper I have used this method exclusively. I have reduced the temperautre to 160 F. with equally as good results.

CAMPHORATED OIL POISONING WITH NO MORTALITY

REPORT OF TWENTY CASES

R. W. BENZ, M.D.
HONOLULU, H. I.

Feb. 9, 1919, I received a message from a local children's institution that one of the inmates was having a "fit." Arriving there twenty minutes later, I found that twenty children were having convulsions. On inquiry I found that the children had been given from 1 to 1½ tablespoonfuls of medicine, presumably castor oil. The dosage had varied according to the ages of the children, who were from 4 to 10 years of age. The medicine was given at 6:30 a. m., and the first child to be taken ill presented his initial symptoms at 7:15 a. m. The children were sprawled all over the dormitory presenting all kinds of symptoms, from an expression of the face indicating nausea to convulsions. The first thing that immediately impressed one on entering the room was the odor of camphor.

It was then discovered that the children had been given camphorated oil (*linimentum camphorae*) instead of castor oil.

SYMPTOMS, TREATMENT AND RESULT

On examination of the most severe case the following symptoms were predominant, all the rest presenting the same symptoms to a minor degree:

Examination.—The child was unconscious and rigid, with the head thrown backward. The color was good except for intense lividity of the lips, which were blue black. The body was cold to the touch. No perspiration was apparent. The pulse was greatly accelerated (120), but showed good volume. Respirations were slow and shallow. No actual count was taken. The eyes were fixed staring straight ahead. The pupils were equally dilated. An odor of camphor was noticeable on the breath. The jaws were locked, and there was a tetanic contraction of the masseters. There was cervical rigidity. The arms showed tonic contraction. The legs were extended. The twitching of oral and buccal muscles was noticeable. The reflexes were not noted.

Treatment.—The milder cases were treated with mustard water, which caused emesis within a few minutes, and within twenty minutes the children were apparently well.

The children more severely affected were immersed in hot mustard water, and when they became relaxed, which occurred within a few minutes, they were forcibly given mustard water. A cupful in practically all cases was sufficient to cause emesis, aided with upward pressure on the abdomen. These patients were well within three or four hours.

In one very severe case there were alarming symptoms for twenty hours, during which time the child was comatose. This child was well in twenty-nine hours.

COMMENT AND CONCLUSION

There does not seem to be any mortality associated with a dose of camphorated oil up to 1½ tablespoonfuls, although in some cases the symptoms are alarming. The treatment seems to be the hasty removal of the stomach contents by means of an emetic, following which the patients rapidly recover.

LIMITATION OF ROENTGENOTHERAPY OF SURFACE EPITHELIOMAS *

WILLIAM THALHIMER, M.D.
MILWAUKEE

In this case, an epithelioma of the skin of the dorsum of the hand was treated by the roentgen ray, and after a resection of a resulting ulcer, a local cure occurred. Subsequently to this, a large tumor appeared in the axilla which proved to be a metastatic squamous cell carcinoma. It is evident that in cases of this nature, if roentgenotherapy is resorted to, it should not be confined to the superficial tumor, but the regional lymph nodes along the path of lymphatic drainage also should be thoroughly treated. Only under these circumstances is roentgenotherapy justifiable. This rule is recognized by roentgenotherapeutists in treatment of epithelioma of the lip, in which they especially caution that the neighboring lymph nodes should also be treated. It would seem that this rule is not so well appreciated in the treatment of epitheliomas of the skin of the extremities. The case here reported illustrates this point and indicates the thoroughness with which roentgenotherapy should be applied when it is used.

In spite of the remarkable advances that have been made recently in roentgenotherapy, it is still a debatable question whether local, operable, malignant disease should be treated by the roentgen ray or by excision. When the tumor is situated on the face, cosmetic results at times may indicate roentgenotherapy, to avoid a scar. Undoubtedly, a wider application of roentgenotherapy is justifiable at this stage of its development, for it is important to determine, without too much risk to the patient, the efficacy of the recently much improved roentgen-ray methods. Since it is certain that these improvements have given a tremendous impetus to the roentgenotherapy of malignant conditions, it is hoped that the report of this case, showing the limitations of purely local treatment, will stimulate roentgen-ray workers to extend their therapy widely enough to include the lymphatic drainage and regional lymph nodes in all cases.

REPORT OF CASE

G. M., man, aged 56, noticed one year previously a small, wartlike tumor on the dorsum of his right hand, half way between the thumb and the forefinger. This was very small at first but soon grew as large as a cherry. This tumor was then treated by the patient's physician for three months with roentgen rays. The tumor disappeared in this time and was replaced by an open ulcer, 2 cm. in width, which refused to heal. A microscopic examination was not made of this. This ulcer was then widely excised, and the skin defect successfully covered by a skin graft. Six months after the first appearance of the tumor, which was about two months after the excision of the ulcer, a small, painful nodule appeared in the axilla. About two months after this, the patient consulted Dr. A. J. Patek, who kindly referred him to me. At this time, Feb. 23, 1919, the right axilla was filled by a mass about 4 by 5 cm. in size. This was tender, and the skin was red and warm over its most prominent part. Beneath this there was a slight fluctuation and there could be felt in the depths a rounded, tense area about 2 cm. in diameter, which also fluctuated. The process appeared to be inflammatory, but because of the previous history, metastatic carcinoma was thought of. The mass was incised by me the same day, and cloudy, serous fluid, containing fragments of degenerated tissue escaped. The lining of the resulting cavity was firm and irregular, and a projecting piece of tissue was removed, which on microscopic examination proved to be squamous cell carcinoma. One week later, I cleaned out the axilla as thoroughly as possible. The tumor was densely adherent to the axillary vein and was dissected away with difficulty. The wound healed by primary union, and the axilla is now being treated by roentgen ray in the hope of preventing a recurrence.

It is interesting to note that the epitrochlear lymph node is not enlarged and therefore is apparently not involved. It is thought that perhaps because of the situation of the tumor the epitrochlear lymph node was not in the path of lymphatic drainage.

STUDIES ON MALARIA CONTROL

II. THE TREATMENT OF MALARIA, WITH THE SPECIAL OBJECT OF DISINFECTING INFECTED PERSONS, ADOPTED AFTER WIDE EXPERIENCE IN MALARIA CONTROL BY TREATING MALARIA CARRIERS IN THE MISSISSIPPI DELTA.*

C. C. BASS, M.D.
NEW ORLEANS

My object is to call attention to the treatment of malaria which has been adopted after a study of different methods of treatment in more than 25,000 malaria-infected persons in Bolivar and Sunflower counties in Mississippi during 1916, 1917 and 1918. Full reports of these experiments in malaria control will be published in due course, but it is hoped that this paper may be read and the treatment advised may be adopted by a larger number of physicians than would result from the extensive report alone.

No attempt will be made here to present the data and observations supporting the method of treatment adopted. Suffice it to say that the treatment here advised has been adopted after three years' observations, in an attempt to learn the most effectual and practical treatment for disinfecting malaria-infected persons.

The treatment for adults is 10 grains of quinin sulphate every night before retiring for a period of eight weeks. For children the dose that gives the same results as 10 grains in adults is: under 1 year, ½ grain; 1 year, 1 grain; 2 years, 2 grains; 3 and 4 years, 3 grains; 5, 6 and 7 years, 4 grains; 8, 9 and 10 years, 6 grains; 11, 12, 13 and 14 years, 8 grains; 15 years or older, 10 grains.

The 6, 8 and 10 grain doses are best administered in the form of two tablets (or if preferred, capsules) containing 3, 4 or 5 grains each. The smaller doses are best administered in aromatic syrup of yerba santa (syrupus eriodictyi aromaticus, N. F.), so prepared that one teaspoonful contains the required dose. The eight weeks' treatment should be prescribed at one time, and the patient should be advised and impressed that he should take the full treatment without missing doses; otherwise a relapse is likely to occur. A physician who cannot impress his patient to this effect has not his patient's full confidence.

---

* From the Department of Experimental Medicine, Tulane University of Louisiana School of Medicine.

* This is one of a series of papers to be published, based largely or entirely on malaria control work conducted jointly by the International Health Board and the Mississippi State Board of Health.

Persons who have acute attacks of malaria should be given one dose of 10 grains (or a proportionate dose for children) three times a day for a period of three or four days, which always relieves the acute symptoms, and then the eight weeks' treatment finally to eliminate the infection.

COMMENT

Treatment of malaria by different physicians varies greatly. In most instances the patient is not disinfected by the treatment but remains a malaria carrier likely to relapse at any time and also likely to be a source of infection to others. Few of the patients treated by physicians in general are actually disinfected, though it is possible and practical to disinfect all. There are no exceptions, barring patients that are moribund. If all physicians succeeded in disinfecting their malaria patients, it would contribute largely to the reduction of the prevalence of the disease in this country.

The treatment described above will disinfect more than 90 per cent. of cases. It would take more than three months' treatment to disinfect 100 per cent. Some persons require much longer treatment than others to kill all their malaria parasites. Whenever there is reason to suppose that a given patient is such an exceptional person, he should be given longer than eight weeks' treatment, without waiting for a relapse to make this necessary. The history frequently indicates those who are especially difficult to disinfect of malaria. In case of a relapse, the full treatment must be repeated and continued longer than eight weeks. In the event of a relapse, necessitating repeating the treatment, no credit can be allowed for any previous treatment.

Quinin (and other cinchona alkaloids) is the only drug known that cures malaria. The sulphate is as effective as any other salt, and more effective than some. The greater solubility of some other salts is no advantage in the treatment of malaria, but on the contrary may be a disadvantage.

Administration of quinin by mouth is the only method to be considered in the treatment of malaria except in rare instances of pernicious malaria, when one or more doses given intravenously may save life. The dose for this purpose should never exceed 10 grains. The bimuriate (quininae dihydrochloricum, U. S. P.) is a good salt for this purpose. Administration by mouth should be started just as soon as practical in such cases.

Physicians who give quinin hypodermically or by deep injection or who contemplate doing so should take a few doses themselves. Such experience will usually quickly quiet one's enthusiasm for the method. I admit that there may be rare instances in which the administration of a dose or two of quinin in this way may be indicated, but it certainly should never be allowed to take the place of administration by mouth, the only practical method of disinfecting infected persons.

Administration of quinin every day disinfects a considerably larger proportion of cases in a given length of time than intermittent treatment with quinin on one or two days of each week. This is contrary to views held by some students of malaria, including my own self at one time, but it is a fact, nevertheless.

Special Article

HOSPITAL SERVICE IN RURAL COMMUNITIES

A PRELIMINARY REPORT

Prepared by Ernst C. Meyer, Director of the Department of Surveys and Exhibits of the Rockefeller Foundation International Health Board

New York

(Continued from page 1136)

PART I. EXTENT OF SICKNESS AND OF DISABILITY DUE TO SICKNESS

Hospital service is obviously closely related to sickness. Its need is reflected in a large way by the number of deaths and number of cases of sickness in a community. Inquiry into the reason for death may throw light on the adequacy of medical care which preceded it. Whether those who survived sickness had adequate care can be determined only by careful study of the treatment received and of the conditions surrounding convalescence.

Information on the extent of sickness and on its care is largely lacking. In 1890, the United States Bureau of the Census gave some attention to morbidity statistics. A considerable area and population were covered. Results tended to show that sickness is more prevalent in country districts than in the city. The census statistics, however, are admittedly incomplete. Table 1 summarizes the results of the federal morbidity census.

TABLE 1.—SUMMARY OF FEDERAL MORBIDITY CENSUS

States	Population	Sick and Disabled	Rate per Thous nd
Northeastern states*	12,312.024	207,302	16.84
Southern states†	4,936,515	91,578	18.55
Cities‡	6,330,441	63,414	10.02

* Included Maine, New Hampshire, Vermont, Massachusetts, Connecticut, Rhode Island, New York, New Jersey and Delaware.

† Included Alabama, Tennessee and Virginia.

‡ Included New York, Chicago, Philadelphia, Brooklyn, St. Louis, Boston, Baltimore, Cincinnati and Washington.

More recent and highly suggestive material was collected by the Metropolitan Life Insurance Company of New York City, which made surveys covering more than 13,000 cases of sickness scattered about in a total population of 637,038 people, a considerable percentage of whom resided in urban communities. The population covered by these surveys consisted of policy holders belonging to "representative groups of wage earners." The information was secured by agents of the company in the course of their regular business in making collections. It was thought that the enumerators of the company, because of personal knowledge of the circumstances in the family life of the groups under their weekly supervision, had a peculiar advantage in obtaining reliable information. "The resulting statistics," a report of the company states, "are believed to be uniquely valuable in that they tend to approach the truth more nearly than do records of sickness inquiry characterized by the hesitancy or reticence of persons to impart more or less confidential information to an enumerator whom they do not know."

Both the survey above referred to and the State Charities Aid Association survey, details concerning which are presented below, define sickness as "an illness so serious that it either necessitates or should have necessitated the patient's going to bed or securing medical aid." Slight illnesses were not taken into account. The Metropolitan Life Insurance Company further distinguished between people who were ill and able to work; and people who were ill and unable to work. The first class were described as merely "sick," and the second as "disabled."

The Metropolitan Life Insurance Company located 13,312 sick individuals among a population of 637,038. This produced a rate of 20.8 per thousand. Of the 13,312 sick, 12,114 were reported disabled. The disability rate thus was 19.1 per thousand; the disability rate for males over 15 years of age was 22.7, and for females of the same age group, 24.1 per thousand. Details are presented in Tables 2 and 3.[3]

A further survey, which went beyond that of the Metropolitan Life Insurance Company in that it inquired with much care into the character of medical aid received, and its adequacy or inadequacy, was conducted by the State Charities Aid Association of New York State in Dutchess County, N. Y., in 1913, and covered sickness which occurred during the sixteen preceding months. A total of 1,600 cases of sickness was discovered in connection with intensive surveys among an aggregate population of about 11,800. It was believed that this population might be regarded as typical of the total population of Dutchess County, which includes 38,500 urban and 49,725 rural residents.

The findings of the State Charities Aid Association survey confirm the results of the surveys of the Metropolitan Life Insurance Company, and suggest the approximate accuracy of both surveys as measures of community sickness.

TABLE 2.—RELATION OF SICK AND DISABLED TO TOTAL NUMBER OF PERSONS INVESTIGATED, TOGETHER WITH THE DISABILITY RATES PER THOUSAND PERSONS INVESTIGATED, CLASSIFIED BY SEX

Area	Persons Investigated*	Persons Sick		Persons Disabled		Disability Rate per 1,000 Investigated 15 and Over	
		No.	Rate	No.	Rate	Male	Female
Boston	97,259	1,902	19.6	1,747	18.0	21.6	21.8
Rochester	34,490	798	23.1	661	19.1	23.2	25.7
Chelsea (N. Y. C.)	24,043	356	14.8	331	13.8	17.6	14.7
Kansas City, Mo.	34,267	862	25.2	816	23.8	23.5	26.1
North Carolina	66,007	1,881	28.5	1,512	22.9	25.1	35.3

Cities in Pennsylvania and West Virginia	374,001	7,333	19.6	6,908	18.5	23.3	22.5
Total	637,038§	13,312§	20.8	12,114§	19.1	22.7‖	24.1‖

* This column represents the total number of inhabitants concerning whom information was collected in the surveys.

† The figures for Pittsburgh and West Virginia are also included with the figures covering cities in Pennsylvania and West Virginia, given elsewhere in this table.

‡ Statistical results of this sickness survey limited to white persons only.

§ Figures for Pittsburgh and West Virginia are not included, as they are contained in the total given for cities in Pennsylvania and West Virginia.

‖ Arithmetical mean for the cities indicated.

A survey of unusual interest and importance was conducted by the Department of Health of the City of New York in 1917. This survey had been preceded by two more limited illness censuses taken in an experimental health district[4] in August, 1915,[5] and in February, 1916.[6] The total number of persons canvassed in 1917 was 56,676, and the total number of persons reported as ill was 1,405. This shows an illness rate of 24.8 per thousand. This rate, it will be noticed, is somewhat higher than that developed by the surveys already referred to. "Every case of illness, no matter how trivial, was classed among the ill." A further explanation of the difference in rates is found in the fact that the New York City census was taken in the month of February when, from experience, the morbidity is found to be highest and was, moreover, taken in two of the heaviest negro districts of the city, where sickness was known to be more general than elsewhere. These districts had been selected because of the great need of intensive health work among the city's colored population. Patrolmen were used in canvassing one district on the west side of the city, and nurses and medical inspectors in the second district, located in Harlem. The census was completed in one day, Feb. 19, 1917. Patrolmen canvassed every family; the nurses and medical inspectors, because of the large area covered in Harlem, did not canvass every family. Those canvassed were, however, considered to be representative of the entire group. Considerable publicity had been given to the census, and details were carefully planned.

TABLE 3.—SICKNESS AND DISABILITY RATES PER THOUSAND POPULATION AS DEVELOPED BY SURVEYS INCLUDING 13,312 CASES OF SICKNESS IN THE AREAS INDICATED

Area	Sickness						Disability					
	Both Sexes		Male		Female		Both Sexes		Male		Female

N. Carolina	28.6	37.1	25.1	31.4	32.6	42.8	22.6	29.9	19.9	25.4	25.7	34.0
Pa. and W. Va.	19.4	24.3	19.7	24.9	19.0	23.7	18.2	22.6	18.6	23.1	17.9	22.2
Trenton	25.8	31.6	25.5	33.0	26.1	30.3	19.9	23.9	19.5	24.8	20.4	23.1

* Black and white races. The rate among the white was 13.6, among the colored, 15.4.

† Black and white races.

Of the 1,405 cases of illness located, 925, or 66 per cent., were reported as "incapacitated." The disability rate on the basis of population covered was 16.3. Certain details developed by the New York illness census are presented in Tables 4, 5 and 6.[7]

In April, 1917, the director of the Framingham (Mass.) Community Health and Tuberculosis Demonstration conducted a sickness survey[8] of Framingham, a city of about 13,000 inhabitants. In the course of this work, 6,582 individuals were reached, and 407 cases of illness discovered. This represents a sickness rate of 62 per thousand. Of the total number of individuals reached, 3,212 submitted to a medical examination with a view to discovery of hidden disease. Among these, 248 cases of sickness were found. This is a sickness rate of 77 per thousand. The group which refused to be examined, and limited cooperation in the census to voluntary admission of sickness, showed 159 cases of illness among 3,370 individuals—a sickness rate of 47 per thousand. These rates are much higher than those recorded in the surveys mentioned above. The explanation is found in a more liberal definition of sickness, the inclusion of a higher percentage of minor conditions, and more intensive publicity. The term "illness" in this census included "*all minor and serious affections in need of medical or dental advice or treatment.*" *Under the sickness* survey of the Metropolitan Life Insurance Company, the term "illness" was restricted to mean "an illness so serious that it either necessitated or should have necessitated the patient's going to bed or securing medical aid." A retabulation of the Framingham sickness survey on the basis of the latter definition established a sickness rate of 18 per thousand. This, it will be noticed, is approximately that of the Metropolitan Life Insurance Company survey. Within a few weeks after this sickness survey had been completed, a special patriotic census was taken in Framingham which covered 3,101 families, comprising 12,300 individuals. This census was taken largely by volunteer lay workers with no special training for the work. The definition of the term illness was the same as that used in the first census. The sickness discovered produced a rate of 32 per thousand.

* This column contains figures developed in the illness census referred to in Footnote 6.

In comparing the findings of the Framingham sickness census as to disability with those of the Metropolitan Life Insurance Company, it is necessary to bear in mind that the agents of the Metropolitan Life Insurance Company were instructed to report only illnesses causing disability, whereas the agents and nurses who made the Framingham survey were instructed to ascertain not only illnesses creating total disability, but minor illnesses as well. By applying the uniform definition of illness to the statistical results of the two censuses, it is found that the percentage of cases in which there was total disability was approximately the same in the two cases.

Summarizing, so far as rather incongruous statistics can be summarized, it would appear that the sickness rate of this country varies from 20 to 25 per thousand, and the disability rate from 16 to 20 per thousand, the average for the former being around 22 and for the latter around 18. When minor and trivial illnesses of all sorts are included, and particularly *ailments which should have medical or dental* advice or treatment, the number of cases of sickness discovered is greatly increased. The rate in such cases has been found to run at from 40 to 70 and more per thousand, according to the thoroughness of the survey. In all probability the sickness and disability rates quoted above are somewhat too low, because of a natural tendency toward concealment of certain forms of sickness, in particular tuberculosis and venereal diseases. Sometimes concealment is unintentional and due to ignorance of the diseased condition. The Framingham census clearly brought out this point. The number of cases of sickness discovered among individuals who submitted to medical examinations was considerably larger than in those

* Note that complete duration of sickness is not known, but only the time which elapsed from the date on which sickness set in until the date of the survey.

cases in which the voluntary admission of the person approached had to be accepted as final. It is interesting, too, that in case of the Framingham census more than half of the people refused a free medical examination. Enough is revealed by these various surveys to demonstrate the fact that sickness and disease are responsible for extraordinary suffering and loss of life wholly aside from the enormous economic loss.

URBAN AND RURAL SICKNESS RATES

There is much reason to believe that the rural sick rate exceeds that of the cities. If this is true, then the rates given on the preceding page, which are based on a mixed population, both urban and rural, are an understatement of conditions of morbidity in the open country. It is generally accepted that sickness rates follow the trend of death rates. If judged by the death rate, the open country undoubtedly was more healthful than the city in times past. During recent years, however, under the impulse of effective health administration in the cities, there has been a constant decline in the urban death rate. The rate in the country regions, on the other hand, has remained much the same. So it has come about that in some states the city rate is now lower than the country rate, the difference being increased with every succeeding year. New York State presents a typical example of this change. Figure 1 illustrates the point.

In comparing city and country death rates, it is well to bear in mind that the two are not closely comparable. The city death rate tends to be somewhat lower because of a preponderance of population in the middle ages, owing to immigration. The country death rate tends to be somewhat higher than in former years, owing to a more complete report and registration of deaths. However, there seems little doubt that the urban death rate is falling much more rapidly than is the rural rate.

Some rather interesting and definite information as to the difference in health conditions between city and country has also been developed in connection with the examination of large numbers of schoolchildren in various states. Health defects appear to be far more common among country than among city schoolchildren. This situation is illustrated by Figure 2.

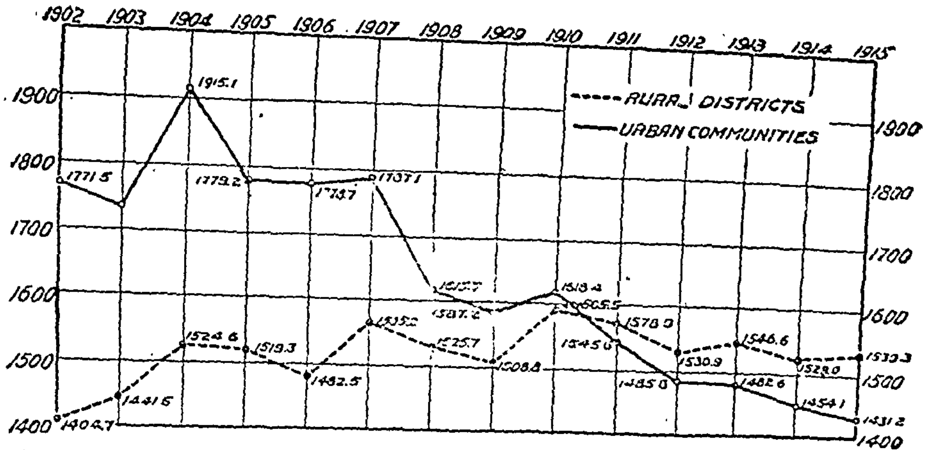

Fig. 1.—The rural and the urban death rates in New York State (communities with a population less than 8,000 classed as rural).

When it is remembered that 12,000,000, or 60 per cent., of the 20,000,000 schoolchildren of the nation attend country schools, the disadvantage in health which the country suffers on this score alone is considerable. Many of the defects of schoolchildren greatly impair usefulness in later years. It is well known that conditions of sanitation at schoolhouses, as well as at large numbers of country homes, beggar description, and that there is much ignorant and false economy in all matters involving health.

Attention may also be called to the fact that in health matters there is strong interdependence of urban and rural communities. Soil, milk and water pollution in the country are likely to be felt in neighboring cities. The typhoid problem has in this respect become classical. The necessity of treating city and country as substantially a part of one and the same administrative unit in health work is being more and more clearly recognized.

ECONOMIC LOSS DUE TO SICKNESS

The losses to society due to sickness are known to be many and heavy. Medical care and drugs must be paid for. Sickness is apt to have far-reaching effects in impairing the living and working efficiency of families affected by it. Then there is the sorrow, and physical and mental suffering, and the loss in actual working days, that is, in earning power. The latter item has been variously calculated and represents an enormous figure.

It is of interest, however, that of the total loss in time due to sickness, 65 per cent. is occasioned among children under 14 years of age. Twenty-four per cent. is among men and women from 15 to 54 years of age, and 11 per cent. is represented by men and women over 54 years of age, and by certain chronic cases, which in the particular survey under consideration were put in the latter group (Fig 3).

The economic loss, that is, the wage loss, falls largely on men in the age group of 15 to 54. In days of sickness this wage time loss is about 12 per cent. of the total sickness time loss. It is on an average 6.7 days per man per year. Interesting calculations have been made to show the number of days lost by sickness among the working population. Thus, for the state of North Carolina, with a population of

1,431,136 over 15 years of age, it has been estimated that no less than 5,294,800 working days are lost per year by the male population alone, and 7,658,400 by the female population. The reader may attach his own value to the worth of a working day. Details are given in Table 7.

ABILITY TO PAY FOR MEDICAL SERVICES

It has been estimated that about 40 per cent. of the population of the United States is gainfully employed, and that 60 per cent. consists of wives, children and old people who are beyond the working age. It has also been estimated that this 60 per cent. of the population require per unit twice as much medical aid as do persons gainfully employed. An overwhelming burden of sickness hence rests on those gainfully employed.

Statistics have been compiled which show that 65 per cent. of the men 16 years of age and over, in the country, received a wage of less than $626 in 1904. Investigation has shown that in the same year it took about $854 a year in New York, and $750 in Buffalo for a family of man, wife and three children under school age to live. Savings are relatively infrequent among families with an income of less than $800. It was also found that the average annual surplus of a group of 200 families was only $15.13. This reduces the margin between economic dependence and economic independence in such cases to just about a single week's wages.[9]

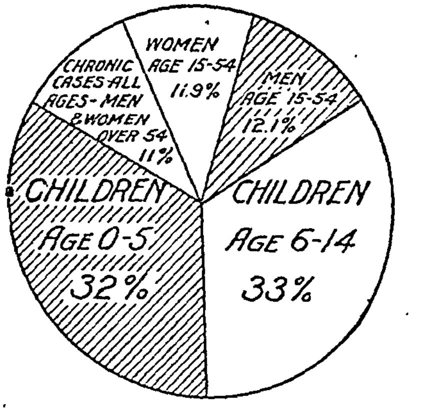

Fig. 3.—Days lost through sickness, classified by age of the sick.

The average duration of sickness among the general population (which includes wage earners) appears to be from six to twelve days a year. From one eighth to one twelfth of a given group of wage earners are every year disabled for work because of sickness. It is not surprising, therefore, that charitable agencies find sickness to be one of the chief factors creating dependency. In Massachusetts it is estimated that $1,500,000 is spent annually by local officials for poor relief on account of sickness. In 1916, sickness was present in 2,016 out of 3,000 families cared for by the New York Charity Organization Society. It was also the cause of need in 1,043 out of 2,043 families under care of the New York Association for Improving the Conditions of the Poor. No less than 42 per cent. of the money spent by this organization for material relief went to families in which sickness was present.

(To be continued)

* In this column are shown the number of persons who, if disabled the year round, would represent a loss in working days equal to that suffered through sickness disability by the total population of the area.
† On the basis of 300 working days in a year.
‡ The figures for Pittsburgh and West Virginia are also included with the figures covering cities in Pennsylvania and West Virginia, given elsewhere in this table.

Therapeutics

THE COAL-TAR ANTIPYRETIC DRUGS

The drugs to be considered are acetanilid, antipyrin and acetphenetidin (phenacetin). Other newer similar drugs have not been proved more efficient or less toxic than these three; hence it is not worth while to discuss other than these. It is essential to state at the outset that these drugs are all similar in their action, and that all are used for the same conditions and for the same therapeutic objects. In overdosage all cause the same symptoms of poisoning, and the treatment of such poisoning is the same in each instance. These drugs do, however, vary as to their dosage, with a corresponding variance in the amount of chemical reaction produced in the body. Antipyrin is very soluble, but is nauseating, in solution, and may cause vomiting. The other two drugs are only slightly disagreeable to the taste, and hence are readily administered in tablet or powder and rarely cause vomiting. Antipyrin, being more irritant than the other two drugs, may produce sufficient irritation of the duodenum to cause urticarial disturbances of the skin. Antipyrin may also cause irritation of the kidneys, even sufficient to cause albumin and blood to appear in the urine. Acetphenetidin and acetanilid in safe doses do not cause skin or kidney disturbances.

Antipyrin is somewhat astringent, and has antiseptic properties. Acetanilid has mildly antiseptic properties, and a few years ago it was largely used in surgical dressings, as it is cheap and nonirritant. Antipyrin causes more perspiration in feverish processes than do the other two drugs. Acetanilid is more depressant to the heart than the other two, but not more so in small proper therapeutic doses. Acetanilid, when first presented, was called antifebrin and was given in dangerously large doses (often 10 grains being given and the doses frequently repeated) and caused many deaths. Also, acetanilid, being the cheapest of these three drugs, entered into most of the antiheadache and antipain nostrums and "patent medicine" powders and tablets, and repeatedly these preparations have caused death. Hence acetanilid received a bad name that has clung to it. It does not deserve it. In proper small doses it is the most efficient of the three, and the dose may be so small that there is no chemical irritation or disturbance from it. It is a clinical fact that small doses of acetanilid are no more likely to cause cardiac depression than are the larger doses of acetylsalicylic acid now so freely taken by the laity.

---

[9] These figures are, of course, quite obsolete today. They are presented solely because they suggest the nature of the economic problem involved, not because they offer a close measure of present-day standards.

Acetphenetidin (phenacetin) is perhaps less of a depressant in therapeutic doses than is acetanilid, but much more must be given, and it more often fails to relieve pain and fever.

The clinical proportionate doses are about as follows: acetanilid, 0.1 gm.; acetphenetidin, 0.3 gm.; antipyrin, 0.5 gm.

ACTIONS DESIRED OF THE DRUGS

The actions desired of these drugs are (1) a lowering of the temperature, and with it, a lowering of the blood pressure and increased perspiration, and (2) cessation of pain.

In ordinary doses these drugs rarely cause any other symptoms. If pain is not acute, sleep may be produced by a general relaxation through these drugs. Muscle spasm is relaxed perhaps more especially by antipyrin.

LIMIT OF SAFETY

The action described above is the only activity desired of these drugs. If the patient becomes cold, the lips blue and the pulse weak, the limit of safety has been more than reached, and the next stage is that of shock, cyanosis and collapse.

Occasionally a patient shows an idiosyncrasy against these drugs, being readily depressed, even by small doses. Most idiosyncrasy, however, is against antipyrin, it causing too profuse perspiration, dizziness and cyanosis, and some somnolence.

CONTRAINDICATIONS

These drugs should not be used (1) in low blood pressure; (2) in weak heart; (3) in anemia; (4) to reduce temperature later than the very first stage of an acute illness, or (5) repeatedly for recurrent pain, lest anemia and chronic depression be caused.

Antipyrin should not be used when there is inflammation or irritation of the kidneys.

TREATMENT OF POISONING

If symptoms of poisoning occur and any of the drug used is presumably still in the stomach, it should be gently washed out, for which purpose the stomach tube is best used. As there is generally great prostration, emetics should ordinarily *not* be used. The rest of the treatment is as for shock, namely, dry heat, a hot water bag over the heart, strychnin, atropin, suprarenal or pituitary extract, and later, digitalis. The foot of the bed should be raised.

If the drug causing the poisoning is antipyrin, large amounts of water should be given to remove the irritant from the kidneys. Alkaline solutions, as sodium bicarbonate, are beneficial in all cases of coal-tar poisoning.

INDICATIONS FOR USE

These drugs may be used:

1. *To Lower the Temperature.*—For this purpose they may be used in the first stage of any feverish process, provided the heart is not weak and the patient not anemic. At the same time that they reduce temperature, they stop or lessen headache, backache and general myalgias; also the heart will be slowed and the blood pressure lowered. The dose of acetanilid and of acetphenetidin is always so small that they do not irritate the kidneys; nor will antipyrin in ordinary doses often irritate the kidneys. Generally, as the temperature is lowered, there is sweating.

2. *To Relieve Pain.*—These drugs are useful in all neuralgias and myalgias, but of little value, in safe dosage, in pain caused by local inflammation or a colic. All pain in the head may be lessened by these drugs, owing to their ability to lower the blood pressure, and hence to diminish the cerebral tension. They can cause sleep only by such action. They are not real hypnotics. Although these drugs will lower blood pressure and quiet a too active heart, it is generally unwise to use them for that purpose, as the heart muscle may be weakened by them. They are often of value in ameliorating the pain of dysmenorrhea.

3. *To Relieve Muscle Spasm Due to Increased Nervous Irritability.*—To meet this indication, antipyrin is perhaps the best drug of the three. For this purpose it is valuable in whooping cough; in the pains of locomotor ataxia; in painful muscle contractions in neuritis; in various forms of muscle twitching, as in chorea, and in spinal irritability. It acts in these conditions by diminishing spinal cord sensibility and lowering reflex irritability.

In whooping cough, antipyrin is a valuable drug, and may be given in 0.05 gm. doses (about 1 grain) for each year of the child's age. It may be dissolved in plain water and given in lemonade or orangeade; or it may be dissolved in peppermint or wintergreen water. Older children may take it in capsules, swallowed with plenty of water. The dose proper for the age may be given three or four times in twenty-four hours, depending on the frequency of the paroxysms. As soon as the paroxysms diminish, the frequency of the dose may be lessened. Coincident with its administration, the child should generally receive small doses of digitalis.

Antipyrin has sometimes been used with success in acute chorea. It has been used with more or less success in large doses for the pains of locomotor ataxia, and is certainly valuable, especially as it obviates the necessity of early administration of morphin for these excruciating pains. In this condition it has seemed to be more valuable than the bromids.

In muscle spasms occurring in acute neuritis it does not seem more valuable than bromids, but absolute rest of the part affected, as a splint in acute sciatic neuritis, is more effective than drugs.

ADMINISTRATION

The dose of acetanilid for an adult is from 0.05 to 0.25 gm. The large dose should rarely be given, and never repeated. A 0.05 gm. dose may be given every hour for six doses; a 0.10 gm. dose every two hours for three doses, and a 0.15 gm. dose every three hours for two doses.

While under the action of acetanilid, the patient should remain at rest, if a feeling of depression is to be avoided. Some practitioners use this drug carelessly, while others, who have observed unpleasant or dangerous effects, are afraid to give it at all. Acetanilid is a very useful drug if used properly.

It should be given as a powder or tablet, and swallowed with plenty of water. A tablet should be crushed with the teeth and not swallowed whole. It is not more safe to give acetanilid with caffein, although when given for headache, in a combination with caffein it may act better than when it is given alone. It is often given with sodium bicarbonate, which is said to somewhat protect the heart. It is well administered as:

	Gm.
Acetanilid	0.3
Sodium bicarbonate	1.0

Make three powders. Take a powder every two hours, with water.

Or, tablets may be kept in the pocket case or office, each containing acetanilid, 0.05 gm., and sodium bicarbonate, 0.20 gm. This allows the dose to be easily arranged for children.

For headache the following is of value:

	Gm.
Acetanilid	0.2
Citrated caffein	0.3
Sodium bicarbonate	2.0

Make two powders. Take one at once, and repeat in two hours, if needed.

Acetphenetidin, antipyrin or acetylsalicylic acid may be used in place of acetanilid, if desired.

Each physician should write his own prescription for combined drugs for his office use. He should not rely on ready-made preparations. Almost all of the headache powders and tablets on the market, "patented" and nostrum, contain acetanilid, or, since the patent rights terminated, acetphenetidin.

The dose of acetphenetidin is from 0.3 to 0.5 gm., and it is best administered in a powder. It may be given in a capsule, but for quick action the capsule should be uncapped before swallowing. Plenty of water should always be taken with it. The same drugs suggested for combination with acetanilid may also be combined with this drug. An efficacious combination for the fever and pains of tonsillitis or influenza is:

	Gm.
Citrated caffein	0.5
Acetphenetidin	1.5
Phenylsalicylate (salol)	1.5

Make five powders. Take one powder every three hours.

Much larger doses of this drug may be given, such as 0.5 gm. or even 1.0 gm., but a large dose should not be repeated.

Antipyrin is best given in solution in water, or it may be given in capsule. The capsule may be uncapped at the moment of swallowing. While the U. S. P. dose is stated to be 0.3 gm., such an amount is a small dose for antipyrin. The ordinary dose is 0.5 gm., and even a much larger dose is often given. A large dose should, of course, not be repeated in the same twenty-four hours. If this drug is given for any length of time, it causes deterioration of the blood and general debility the same as does acetanilid. A patient may acquire a tolerance to it, especially one suffering from locomotor ataxia.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

DIPHTHERIA TOXIN-ANTITOXIN MIXTURE.—It is well established that a far more durable immunity against diphtheria is established by the use of a mixture of diphtheria toxin and diphtheria antitoxin than by the latter alone. The immunity does not appear until a considerable period of time has elapsed and for this reason the mixture is not applicable in the presence of an outbreak of the disease, in which case it is better to use an immunizing dose of antitoxin alone.

Various mixtures of toxin and antitoxin have been used, but in general the over neutralized mixture seems to be preferred. Several doses are usually required to induce immunity.

The toxin-antitoxin mixture finds its greatest field of usefulness in the immunization of the inmates of children's homes and asylums, those who often come in contact with diphtheria, schoolchildren, and children below the school age.

Only those persons who are positive to the Schick test need be immunized and the progress of the immunization may be determined by the response to the Schick test at intervals during the period of immunization.

Lederle Antitoxin Laboratories, New York. (Schieffelin and Co., New York.)

Diphtheria Toxin-Antitoxin Mixture.—A mixture consisting of 5 L+ doses of toxin and 6.25 units of antitoxin, marketed in rubber-stoppered vials containing one dose. Three doses are packed in each carton.

MERCURIALIZED SERUM.—A solution of mercuric chloride in normal horse serum diluted with physiological sodium chloride solution. It is prepared by the method of C. M. Byrnes (J. A. M. A. **63**:2182 [Dec. 19] 1914).

Actions and Uses.—Mercurialized serum is proposed for the treatment of syphilis, particularly the cerebrospinal type. This is an attempt to produce a preparation which, while therapeutically active, is noncorrosive, has a low toxicity and slight local irritative action, does not coagulate serum albumin, and which consequently is adapted to intraspinal use and can be used intravenously without danger of phlebitis.

Dosage.—Intraspinally, 30 Cc. of a solution, the dose containing the equivalent of 0.0013 Gm. (1/50 grain) mercuric chloride, after *first* withdrawing sufficient spinal fluid to reduce the pressure to 30 mm. (water). The dose may be increased, when tolerance is established, to 30 Cc. of a stronger solution, the dose containing the equivalent of 0.0026 Gm. (1/25 grain) mercuric chloride. Intravenously, 2 Cc. of solution, the dose containing the equivalent of 0.0055 Gm. (1/12 grain) mercuric chloride.

Mercurialized serum is prepared by adding to a solution of mercuric chloride sufficient normal horse serum to dissolve the precipitate first formed and then diluting to the desired volume with physiological sodium chloride solution.

Mercurialized Serum-Lederle.—A brand of mercurialized serum complying with the N. N. R. description.

Manufactured by Lederle Antitoxin Laboratories, New York (Schieffelin & C., New York). No U. S. patent or trademark.

Mercurialized Serum-Lederle, Dilution No. 1.—Each package contains mercuric chloride 0.0013 Gm. (1/50 grain) in 30 Cc. of diluted normal horse serum, and a complete equipment for intraspinal administration.

Mercurialized Serum-Lederle, Dilution No. 2.—Each package contains mercuric chloride 0.0026 Gm. (1/25 grain) in 30 Cc. of diluted normal horse serum, and a complete equipment for intraspinal administration.

Vocal Gymnastics for Stammerers.—Vocal gymnastics, if thoroughly practiced, will not only intensify the auditory images of the stammerer (thus correcting forgetfulness of the sound of the vowels) but develop stronger vocal cords, producing a new voice and giving an easier control, thus removing overinnervation, or the straining to produce sound. —*School Health News*, New York.

THE PROVISION FOR CHILDREN IN THE INCOME TAX CREDITS

In addition to the personal exemption of $2,000 allowed to a husband and wife living together, the income tax act provides for this additional credit:

> $200 for each person (other than husband or wife) dependent upon and receiving his chief support from the taxpayer, if such dependent person is under eighteen years of age or is incapable of self-support because mentally or physically defective.

We do not know the theory on which the precise sum equivalent to one fifth of the credit allowance for adults was incorporated into the act as an evident exemption for the support of children. It has doubtless received careful consideration from the economists in whose hands the provisions for the tax budget rest; and it presumably represents the consensus of wisdom of the experts in this field.

A prominent American daily newspaper recently asked in its editorial columns, "On what provender did the framer of the income tax law which allows $200 exemption for the support of each child rear his own offspring?" This is a personal question best answered by the individual referred to. Speaking in a serious vein, it is not impossible to analyze the figures from the standpoint of the average family budget and to consider whether the provision for children represents a just expression of their share in the essential expenditures for the necessities of life.

The "ideal division" of an income of $1,000 a year has been thus expressed: food, 30 per cent.; rent, 20 per cent.; clothing, 15 per cent.; operating expenses, 10 per cent.; "higher life," 25 per cent. A study made a few years ago by Winifred Stuart Gibbs[1] on the minimum cost of living in families of limited income in New York, before the present greatly increased price of food and clothing, indicates an actual expenditure of between $290 and $390 per person per year instead of the $300 postulated in the ideal scheme. These are not items from the household expenditure of the fairly well-to-do classes, but rather the expression of needs among the less-well-to-do families at a time when the purchasing power of money was decidedly greater than at present.

Let us apply such facts to the provisions of the income tax act. Thirty per cent. of an exemption of $2,000 represents $600 as a reasonable food budget for two adults. If we place the requirement of the woman at 0.8 that of the man, $600 would be expected to provide the diet for 1.8 family units. Assuming an average family of five, i. e., including three children, whose ages are distributed for purposes of argument at 16, 10 and 2 years, respectively, their dietary needs may be expressed as 0.9+0.6+0.3, or 1.8 units —approximately the same as that of the two parents. These figures for the relative calorific needs of food according to age and sex are higher than those accepted in former years for children, but they accord more fully with modern knowledge and were adopted by the Interallied Scientific Food Commission as a basis of its discussions and recommendations. According to the tax act the three children would entitle the head of the family to an additional exemption of $600. Thirty per cent. of this sum, assigned to the provision of food, represents only $180, or slightly more than one dollar per week for each child. But perhaps in these days of conservation we are not expected to provide for education, recreation and saving, not to mention clothing and shelter, for the younger members of the household, except at the expense of the "higher life" of the adults.

UNDERNUTRITION AND DISEASE—A SURVEY OF WAR-TIME DANGERS

In last week's issue of The Journal,[1] the food situation in Germany, as presented by the men of science of that nation, was brought to the attention of our readers. The physiologist Rubner has pictured the condition as one of undernutrition and malnutrition of the population. He remarks that the nutrition of the immediate future involves a problem different from that of the past; it will mean reparation of the enormous depletion of the body reserves of the people at large. The laws of hygiene, says Rubner, must be restored to dignity. When the condition of nutrition of the masses is restored, the desire to work, the capacity for performance, and initiative of body and mind will return. But he adds that the program calls for patience, since convalescence cannot be accomplished in a day. Bread and potatoes do not suffice to produce muscle. Compulsory rationing, which never properly provides for the special nutritive needs of the individual, must be discarded as soon as a return to nutrition-promoting rather than depleting systems of diet becomes possible.

What Germany's food shortage, which began to be acute in 1916 and especially pronounced in 1917 and thereafter, has meant in clinically observable ways has been portrayed by Kraus[2] of the medical clinic at the Charité Hospital in Berlin. He reports diminished resistance to disease, hastening and intensification of the course of certain maladies, the appearance of an illness characteristic of hunger, and a decided increase in mortality. The deleterious effects of marked decreases of the total food intake in general have been most pronounced in institutions, such as prisons, asylums and orphanages, in which the food supply was limited to the inadequate governmental ration. In such establishments those who were physically well suffered from the inanition no less than did the sick and ailing. Kraus has given an instructive account of the disease known as war edema, which has made its appearance wherever food supplies have been pronouncedly deficient. In Germany the "starvation edema" is described as a malady conspicuous particularly in the colder season among men who have been compelled to work with a food intake of less than 1,300 calories a day containing little fat, not more than 50 gm. of protein, and a large proportion of indigestible cellulose-containing food products. Kraus states that thousands, emaciated to even less than half of their former weight, have suffered from this disease. The mortality sometimes amounted to 50 per cent. The incidence of tuberculosis seems to have increased; and as a result of undernutrition, the protective devices of the organism, such as are expressed in immunity reactions, have deteriorated.

[1] The Food Crisis in Germany, editorial, J. A. M. A. 72:1160 (April 19) 1919.

Aside from the inadequate quantitative relations of the war-time ration, the changes in the character of the food supplies have likewise not failed to produce harm. There is an ever growing list of cases of intestinal disturbances attributable to the monotonous, voluminous, poorly digestible, carbohydrate diet. The variety of the afflictions includes gastric dyspepsia with achylia, occasional diarrheas, intestinal fermentations, constipation with marked catarrhal conditions of the bowel, and not infrequently severe ulcers. Kraus has emphasized the essential deficiencies of the German rations by pointing out the need of fat, condensed milk, meat, digestible carbohydrate, fresh fruit, tea and coffee, as well as cereals more suitable for the preparation of better bread. Czerny, the pediatrician, has likewise emphasized the conditions which the food crisis has brought about in the health of German children, and points out to what extent they have failed to obtain protein and fat in recent years. Czerny reminds us of the fact, familiar to every practitioner, that bread and potatoes do not constitute a complete diet for youth. The results of such a limited ration fortify this conclusion.[3]

THE CRISIS IN PNEUMONIA

The recovery of the pneumonic patient by crisis is one of the most satisfactory and interesting clinical phenomena that come under the observation of the physician. The investigations of few problems can be more valuable than those that are concerned with the study of the mechanism involved in this reaction. It is true that no startling changes have taken place in the treatment of this disease during the last decade, except possibly in the treatment of the rather limited class of Type I cases. Nevertheless, our knowledge of pneumonia has been measurably extended, and with the broadened point of view has come greater possibility.

In a recent study, Weiss[1] reaches the conclusion that we must consider a dual source of intoxication in pneumonia, the one a specific sensitizing protein identified as a pneumotoxin and derived from the disintegrating organisms, the other an extremely toxic albumose, derived as a digestion product from the autolyzing exudate. With this as a basis, hereafter we must consider at least two corresponding biologic balances in the crisis mechanism: (*a*) that of the antigen and antibody, wherein we seek to explain the crisis as a destruction of the antigen by the antibodies, and (*b*) the ferment-antiferment balance, according to which the crisis may be supposed to occur when the protease liberated from the leukocytes or thrown into the circulation from distant organs is able to overcome the inhibition of the antiferment present in the blood and the exudate.

Of the former of these two balances we possess a fairly clear picture. Blake[2] has recently pointed out that patients "developing an excess of precipitins and agglutinins have invariably recovered shortly after or coincident with the appearance of these antibodies." On the other hand, "cases showing a progressive increase in the excess of antigen (circulating) without the development of demonstrable antibodies have invariably been fatal." Analogous results have been reported with respect to the opsonins.

Of the ferment-antiferment balance we as yet know relatively little. Von Müller gave impetus to studies in this direction, and Jobling and his associates[3] have emphasized the fact that the huge mass of slowly autolyzing exudate in the lung is the most important source of toxic material. According to their conception, the crisis represents merely the point when active autolysis is established and a rapid splitting of the accumulated exudate to nontoxic products takes place. The precise mechanism involved in this digestive process is as yet undetermined. Three hypotheses deserve consideration: (1) that the crisis represents actual saturation of a possible lipoidal antiferment by means of the great excess of leukoprotease that must be liberated from the leukocytes present in the exudate; (2) that it is due to the activation of the proteolytic ferments by a progressively increasing acidity of the exudate, and (3) that the inhibiting substances are themselves inactivated by a relative shifting in the hydrogen-hydroxyl concentration. Possibly all three changes occur more or less simultaneously and tend to bring about local conditions favoring rapid autolysis. Since autolyzing lung exudate, according to the researches of Almagia, forms an unfavorable medium for the growth of the pneumococcus, the reflex effect of these biochemical alterations on the bacterial proliferation is evident.

[3] Jobling, J. W.; Petersen, W. F., and Eggstein, A. A.: J. Exper. Med. **22**: 568, 1915.

No matter whether our future advance in the therapy of pneumonia will be by means of immunity or chemotherapy or through such biochemical studies as those of Weiss, the prospect of widening methods of attack of the problem is encouraging.

Current Comment

STANDARDIZED MILK

The use of the term standardized or "adjusted" milk for milk in which the original ratio of fat to the other milk solids has been altered by the removal or addition of cream or by the addition of skim-milk is becoming so general that it is timely to discuss, as Van Slyke[1] has recently done, the implications of the expression and the significance of the practice itself. Standardization of milk in this sense consists essentially in bringing about a more uniform composition by removing all or most of the fat that is in excess of the legal standard (usually 3 per cent.) or by adding cream to normal milk that has for one reason or another dropped below the legal standard. As well known, normal Jersey milk usually exceeds the maximum fat standard by a considerable margin; normal Holstein milk may at times fall below. The advantages of the adjustment from the side of the distributor are obvious: Such a grading down or grading up to the legal standard enables large dealers to furnish milk with a relative uniform composition conforming to legal regulations, and to equalize the nutritional quality of milk derived from producers scattered over a wide territory. The disadvantages are mainly the inevitable tendency of such a practice to lower the fat content of milk to a point hardly if at all above that of the minimum legal standard. It is perhaps not necessary to add that this would eventually lead to the general marketing of milk with a considerably lower percentage of fat than that which now prevails. Normal milk with 4 or 5 per cent. of fat would practically disappear. On the sanitary side, the extra handling which such adjustment would involve would expose the milk to possible contamination unless special care were used. On the other hand, objections based on the fact that standardization disturbs the normal relations of fat and solids not fat can have little weight. The "modification" of milk for infant feeding has shown plainly enough that entirely normal cow's milk is not an ideal food for every human organism, and may be changed in various simple ways greatly to the advantage of the individual consumer. Van Slyke suggests that the temptation to indulge in profiteering by excessive fat removal may be met by requiring the labeling of containers of "standardized" milk with the specified minimum percentage of milk fat. This would be in line with the general movement to give the consumer true information as to what he is buying. From time immemorial the purchaser of "a pig in a poke" has come off second best. The fair and honest dealer, as well as the consumer, has much to gain from such a regulation, since he is thereby removed from direct competition with the greedy milk "adjuster" who skims milk down to the legal limit. Proper sanitary safeguards should, of course, be thrown around the process of standardizing milk. Van Slyke makes the excellent recommendation that a special state license should be required for those engaging in milk standardization, and that suitable methods and conditions be prescribed for the process. There has been in the past some reluctance on the part of food officials to take adequate cognizance of the frequency and importance of the practice of milk standardization. The awkward problems it raises have perhaps something to do with this; but it would now seem as if the time had come to deal more directly with a matter that has obvious relations with economic nutrition and with sanitation.

ANTHELMINTICS

The accounts of the therapeutics of infestation with the more familiar and long known intestinal parasites, such as tapeworms, roundworms and threadworms, almost resemble chapters from the history of medieval medicine. Extracts of unfamiliar plants are favorite items. Spigelia, brayera, pomegranate, pumpkin seed and male fern are among the valued names in the domain of anthelmintic treatment. A moment's consideration will make evident to the student of this question that the accurate scientific study of the comparative efficiency of such substances, old or new, against intestinal parasites is complicated by the lack of a dependable test object. The direct therapeutic test on man is seldom feasible, and the results thereby obtained are not easily evaluated with that degree of even semiprecision that attends a bio-assay of many crude drugs or potent substances in contrast with isolated active principles. Fortunately it has been found that the easily obtainable earthworm reacts with symptoms of toxicity to all clinical anthelmintics, just as do the parasitic intestinal worms. This fact has enabled Sollmann[1] of the Pharmacologic Laboratory at the Western Reserve University to reinvestigate the claims long made for certain crude products. He finds that many substances which are toxic to earthworms produce a primary irritation resulting in a withdrawal of the worm from the neighborhood of the poison.

---

[1] Sollmann, Torald: Anthelmintics: Their Efficiency as Tested on Earthworms, J. Pharmacol. & Exper. Therap. 12: 129, 1918.

By virtue of this effect, says Sollmann, anthelmintics doubtless often "expel" the parasite when the concentration does not rise sufficiently high to kill the worm. Spigelia, long recommended for the expulsion of the roundworm, is found to have rather feeble toxicity. But fresh (germinable) pumpkin seed and squash seed are quite highly efficient, the active principle being soluble in water and destroyed by boiling. Sollmann points out that in view of their cheapness, availability, and presumably low toxicity to man, renewed clinical interest in these humble products is indicated. This, we may add, is doubly true at a time when the supply of less common drugs is still far from abundant.

THE UNIVERSITIES AND THE PUBLIC HEALTH

Many years ago, Thomas H. Huxley said that what people call applied science is nothing but the application of pure science to particular classes of problems. The growing realization of this truth is one of the factors that are rapidly changing the attitude of the older universities toward those questions that directly involve the progress and welfare of mankind. The day has passed when it was fashionable to select a form of education devoid of science, and a collegiate career "devoid of continuous intellectual effort." Those persons who are engaged in solving the "practical affairs" of life have begun to realize that familiarity with scientific research as it is conducted in university laboratories is a distinct advantage. On the other hand, even the most orthodox of the great educational centers are beginning to experience a revolution of attitude toward those technical problems which demand a solution for the sake of national progress. The war has shown how well the American university could meet the test of great problems having more than so-called academic interest. A peculiarly promising phase of this newer attitude is seen in the growing enthusiasm of our universities for the recent development of preventive medicine and the movement for public health. Not long ago practical hygiene was something apart from the collegiate institutions. In response to demand for appropriate training, special courses began to be provided in a few university centers. President Vincent of the Rockefeller Foundation recently traced this development in an address at the anniversary exercises of Johns Hopkins University.[1] Pennsylvania took the lead in 1909, followed the next year by Harvard and the Massachusetts Institute of Technology, which cooperated in establishing a curriculum. By 1915, eight other institutions were giving more or less attention to the training of public health officers. The latest academic affiliation of the public health movements is found in the new School of Hygiene and Public Health, which opened its doors at Johns Hopkins University last October as an institution with an individuality apart from that of the closely affiliated medical school, hospital and other university departments. With each new establishment for the prosecution of this educational work, added dignity is given to the training of public health officers, laboratory men, specialists in epidemiology, field workers of all kinds, public health nurses and others. Verily, times and the attitudes of educators change. Public needs can no longer be ignored, even if they represent the seemingly ultrapractical. As Vincent summarizes the tendency of the times, when many things seem uncertain and there are some reasons for grave anxiety, hope and courage are found in the idea of the university, a center of research, of scientific idealism, of professional pride, and of loyalty to the community, entering the field of public health.

WHAT IS THIRST?

The sensations of hunger and thirst are sometimes related to various pathologic manifestations in such an unusual degree as to give concern to the physician respecting the manner in which they are to be satisfied. There are instances when the abolition of the pangs of hunger and thirst becomes truly a remedial measure. How are these sensations to be interpreted? What is their physiologic and psychologic background? The extensive investigations of Cannon at Harvard and Carlson at Chicago, in this country,[1] have contributed fundamental facts bearing on the nature of hunger. In distinction from appetite for food which is related to previous experiences that have yielded pleasurable sensations of taste and smell, the sensation of hunger has come to be definitely associated with powerful contractions of the empty or nearly empty stomach. The essential novelty or importance of this demonstration lies in the fact that a local origin is given to the hunger pangs, so that they can no longer be regarded primarily in the light of a "general sensation" representing some vague need of the body as a whole. In the past, thirst likewise has been the subject of a diversity of explanations. The popular conception represents it as a general sensation. Thus, half a century ago Schiff[2] declared that it arises from a lessened water content of the body, a condition in which the entire organism suffers. The local reference to the mouth and throat, like the local reference of hunger to the stomach, was said to be due to association of experiences. In a review of the various conceptions regarding the physiologic basis of thirst, Cannon[3] has championed the less generally accepted theory that thirst is a sensation of local origin. According to him the preeminent factor is the relative drying of the mucosa of the mouth and pharynx. This may result either from excessive use of the passage for breathing, as in prolonged speaking or singing; or it may be caused by deficient salivary secretion. The latter, according to Cannon, represents true thirst dependent on the fact that the salivary glands, which keep the buccal and pharyngeal mucosa moist, require water for their action. In contrast with other organs that may experience the same needs, the importance of the failure of the action of the salivary glands to the mechanism of the water supply of the body lies, to quote Cannon, in the strategic position of these glands in relation to a surface that tends to become dry by the passage of air over it. If this surface is not kept moist, discomfort arises and with it an impulse to seek well tried means of relief. Thus, Cannon concludes, the diminishing activity of the salivary glands becomes a delicate indicator of the bodily demand for fluid.

THE TEMPERATURE OF INFLAMED PERIPHERAL TISSUES

Inflammation is defined by MacCallum[1] as a complicated vascular and cellular response, which follows almost immediately on the injury, and is adapted, by bringing much blood to the spot and pouring out its elements on the injured tissues, to prevent the extension of the injury, hold in check the injurious agent, or even destroy it. An incident to this process as it occurs in peripheral areas of the body is a rise in the local temperature. This is commonly asserted to be due to the increased flow of blood to the inflamed part. Accordingly, the inflamed region is not supposed to have a temperature higher than that of the blood in the interior of the body. This widespread conviction has been fostered by textbooks and tradition, despite the fact that the hyperemia attending inflammation is by no means the only conceivable cause of the warmth perceived. There are tissues in the organism which unquestionably warm the blood; indeed, the maintenance of temperature must in the long run be dependent on a heat supply from within. At the laboratory of physiology in the University of Genoa, Italy, Segàle[2] has reinvestigated the possibility of an excessive localized production of heat in peripheral inflamed areas. He points out that in inflammation as well as in muscular contraction there may be notable local chemical activity. The circulation in both of these cases exercises its normal function, with the tendency of equalizing the temperature of the various areas. Segàle's calorimetric observations lead him to the conclusion, in contradiction to current beliefs, that the heat of inflamed parts has its origin primarily in the local biochemical activity of the cellular elements which participate in the inflammatory process. Special experiments supported the view that the increase in the temperature of the inflamed area is due to a local cellular hyperfunction; for when this cellular activity was paralyzed, the augmentation did not occur. According to this contention, we have been placing the cart before the horse in our conventional interpretation of inflammatory hyperemia. Segàle maintains that the latter, instead of being a necessary and constant source of the inflammation, must be considered a natural physiologic compensation for abnormal localized liberation of heat by the overactive cells of inflamed regions.

Medical Mobilization and the War

Personnel of the Medical Corps

For the week ending April 18, the Medical Corps contained 18,745 officers, a decrease of 263 from the previous week. The Medical Reserve Corps contained 1,609 officers. The total number of medical officers discharged since the beginning of the war is 19,091.

Overseas Hospitals Patients in This Country

On March 31, there were 38,214 patients from overseas under treatment in Army hospitals in the United States, and also 18,765 domestic patients, making a total of 50,979 patients under treatment.

Weekly Bulletin, A. E. F.

(March 24, 1919)

This *Bulletin* is devoted to a discussion of a sanitary water supply, and especially to general consideration of typhoid.

DELOUSING OF TROOPS

Interesting figures are presented as to progress in delousing of troops. The most recent figures show that only 1.9 per cent. of troops are at present louse infested. The improvement in conditions is attributed to special efforts which have been made both by increasing facilities and attention to the subject. As an explanation of reports received from the United States that troops were arriving home louse infested, the statement is made that this is due to the condition of some of the ships on which the troops are carried. On February 28 it was necessary to take ashore the entire crew from the New Amsterdam for delousing purposes.

WEEKLY REVIEW

The total number of communicable diseases is decreasing with slight increases in chickenpox, diphtheria and typhoid. A slight increase has also been noted in the venereal disease rate, chiefly in Base Section No. 1 and the advance section. Over 50 per cent. of the new cases reported resulted from failure to take prophylactic treatment.

(March 31, 1919)

In this *Bulletin* officers are again cautioned as to the importance of making accurate reports of communicable diseases.

WEEKLY REVIEW

The measles rate and the rate for typhoid continue high. A small epidemic of measles developed among labor troops at Le Mans. The venereal disease rate has risen.

Distinguished Service Medals

Secretary Baker personally presented distinguished service medals on April 5 to the following named medical officers:

Dr. HUGH H. YOUNG, formerly Colonel, M. C., U. S. Army, Baltimore. For exceptionally meritorious and distinguished services. He has, by his constant application, tireless energy and foresight, lowered the nonefficiency rate of combat organizations, due to certain contagious diseases, far below prewar anticipations and has thereby aided in the conservation of manpower to a degree never before attainable.

Dr. WILLIAM S. THAYER, Baltimore, formerly brigadier-general, U. S. Army. For exceptionally meritorious and distinguished services. As chief consultant in medicine of the A. E. F., with untiring zeal he devoted his time, energy and high professional talents in promoting the organization of eminent medical officers for the prosecution of efficient treatment among the sick and wounded of the A. E. F. Largely through his individual efforts the treatment of the sick was so standardized, coordinated and proficiently perfected, as to result in a direct saving of many lives and a consequent conservation of manpower and morale of these forces.

JOHN M. T. FINNEY, Baltimore, Brigadier-General, U. S. Army. For exceptionally meritorious and distinguished services. He rendered distinguished services in the organization of surgical teams for the purpose of affording expert surgical aid to the wounded in the immediate vicinity of the battlefield. He had done much to standardize the practice of surgery in war, and giving so freely of his professional experience and skill. He has in many ways rendered services of exceptional value to the Government.

Distinguished Service Awards

The commander in chief, in the name of the President, has awarded the Distinguished Service Cross to the following named medical officers:

JAMES H. S. MORISON, Lieut., M. C., U. S. Army, Cumberland Gap, Tenn., attached 117th Infantry. For extraordinary heroism in action near Bellicourt, France, Sept. 29, 1918. After being knocked unconscious into a shell hole, and although suffering acutely from the shock, Lieutenant Morison rejoined his company and continued to care for the wounded in the open and under intense shell fire. His respirator having been blown away by the exploding shell, this mission was rendered much more precarious by enemy gas shells. He remained at his first-aid station through an intense barrage which killed several of the stretcher bearers and helpers at this point, evacuating the wounded with great rapidity until he was severely wounded and forced to be evacuated.

---

[1] MacCallum, W. G.: A Textbook of Pathology, 1918, p. 128.

[2] Segàle, M.: The Temperature of Acutely Inflamed Peripheral Tissue, J. Exper. Med. **29**: 235, 1919.

LESTER L. PRATT, passed asst. surg., U. S. Navy. For extraordinary heroism in action in the Bois de Belleau, France, June 11, 1918. Although he had been wounded under the left eye, almost blinded by gas fumes, and his dressing station wrecked by shell fire, Surgeon Pratt remained at his post working under the most trying conditions until all the wounded had been safely evacuated.

ORLANDO H. PETTY, passed asst. surg., U. S. Navy, Philadelphia, Pa. For extraordinary heroism in action near Bucy, France, June 11, 1918. While Surgeon Petty was treating wounded under bombardment of gas and high explosive shells he was knocked down and his gas mask torn by a bursting gas shell, but he discarded his gas mask and continued his work. Later, when his dressing station was demolished by another shell, he helped carry a wounded officer through the shell fire to a place of safety.

FRANK R. WHEELOCK, Capt. M. C., U. S. Army, 313th Infantry, Scranton, Pa. For extraordinary heroism in action near Malancourt, France, Sept. 26-30, 1918. Working in areas that were continually being swept by machine gun, rifle and shell fire, Captain Wheelock worked voluntarily and unceasingly giving aid, food and water to the wounded. Throughout the entire operations Captain Wheelock showed utter disregard for his own safety, being knocked down many times by shell explosions. For two nights he worked as a stretcher bearer, carrying patients to places of safety, after giving them medical attention during the day.

SHADWORTH O. BEASLEY, major, M. C., U. S. Army (deceased), 76th Field Artillery, San Francisco. For extraordinary heroism in action near Les Petit Bordeaux Woods, France, July 14 to 16, 1918. During the entire action, Major Beasley braved the danger of continuous shell fire by constantly searching for wounded and administering treatment.

CONRAD WESSELHOEFT, Capt., M. C., U. S. Army, 102d Infantry, Boston, Mass. For extraordinary heroism in action near Verdun, France, Nov. 8, 1918. Captain Wesselhoeft went forward, under heavy machine-gun fire, to the aid of a wounded soldier. The fire was so heavy that they were compelled to remain in the shell hole until nightfall, when he brought the wounded man to our lines.

JAMES R. LISA, Lieut., M. C., U. S. Army, 105th Infantry, Calumet, Mich. For extraordinary heroism in action near St. Souplet, France, Oct. 18, 1918. After his battalion had been compelled to withdraw because of enfilading fire, Lieutenant Lisa displayed marked bravery in going forward and attending wounded men whose evacuation was impossible because of the intense fire.

THOMAS H. ROYSTER, Lieut., M. C., U. S. Army, 30th Infantry, Tarboro, N. C. For extraordinary heroism in action near Crezancy, France, July 15, 1918. When casualties, during the offensive of July 15, had become so great that it was necessary to work in the open. Lieutenant Royster exposed himself to the severe fire for ten hours, dressing and caring for the wounded.

JOSIAH A. POWLESS, Lieut. M. C., U. S. Army (deceased), 308th Infantry, Oneida, Wis. For extraordinary heroism in action near Chevieres, France, Oct. 14, 1918. When notified that his colleague, Captain James M. McKibben, had been wounded, Lieutenant Powless immediately went forward to his assistance. He crossed an area subjected to intense machine-gun and constant artillery fire, reached his colleague, whose wound proved to be fatal, and, after dressing his wounds, had him carried to the rear. Lieutenant Powless was seriously wounded while performing this service.

WALTER W. MANTON, Capt., M. C., U. S. Army, Detroit, 26th Infantry. For extraordinary heroism in action at Soissons, France, July 18, 1918. Accompanying his battalion in the attack, Captain Manton was with the second wave when he sustained a compound fracture of the right forearm from a bursting shell. He, nevertheless, refused to go to the rear, but remained on duty until the final objective was reached in the afternoon, attending the wounded and directing their evacuation.

DWIGHT DICKINSON, JR., passed asst. surg., U. S. Navy, attached to 2d battalion, 5th regiment, United States Marine Corps. For extraordinary heroism in action near St. Etienne, France, Oct. 4, 1918. Under terrific shell and machine-gun fire, Passed Asst. Surg. Dickinson attended the wounded with utter disregard for his own safety. When a shell struck the dressing station which he had established in an advanced zone, he rushed to the assistance of the wounded, and, through his devotion to duty, many lives were saved.

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

NOTE.—In the following list, L., signifies lieutenant; C., captain; M., major; L. C., lieutenant-colonel, and Col., colonel.

ALABAMA

Asst. Surg. PETER J. GORMAN, proceed to East Norfolk, Mass., for inspection of army hospital which has been offered to this service.

Pharm. F. J. HERTY, proceed to Washington, D. C., for special temporary duty for about one month in connection with investigation of stream pollution and influenza.

Acting Asst. Surg. ANDREW J. ANDERSON, proceed to Dansville, N. Y., and report at the U. S. Public Health Service Hospital for duty.

Acting Asst. Surg. W. C. SCHROEDER, proceed to the United States Public Health Hospital at Greenville, S. C., for duty.

Acting Asst. Surg. E. W. SCOTT, relieved at Washington, D. C., proceed to the U. S. Public Health Service Hospital at Jacksonville, Fla., for duty.

Asst. Surg.-Gen. L. L. LUMSDEN (Reserve), relieved from duty from the Emergency Fleet Corporation; proceed to Washington, D. C., and resume active charge of the studies and demonstration of rural sanitation.

Surgeon G. B. YOUNG, relieved from duty with the Navy Department and at Norfolk, Va.; proceed to Stapleton, N. Y., and assume charge of the marine hospital.

Passed Asst. Surg. ROBERT OLESEN, attend meeting of the State Medical Association of Alabama at Mobile, Ala., April 16, 1919; proceed to Birmingham, Ala., to deliver an address for the Community Congress on April 2, 1919.

Passed Asst. Surg. F. A. CARMELIA, assume charge of a survey covering the cooperative supervision of drinking water supplies by Federal and State Authorities.

Asst. Surgeons W. F. FOX, L. L. WILLIAMS, Jr., D. J. PRATHER, and R. L. DeSAUSSURE; report to chairman of board of medical officers, April 7, 1919, for examination to determine their fitness for promotion, at Washington, D. C.

Asst. Surg. H. A. SPENCER, relieved at Pensacola, Florida. Proceed to Washington, D. C., for temporary duty in the office of the chief medical advisor of the Bureau of War Risk Insurance.

Asst. Surg. R. W. HART, proceed to Secaucus, New Jersey; inspect army hospital to determine its fitness for Service use.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

ALABAMA

Base Hospital Transferred.—Surg. John T. Burkhalter, U. S. P. H. S., on duty at Mobile, has taken over the base hospital at Camp Sheridan, near Montgomery, which has a capacity of 1,000 beds, and in the future is to be under the charge of the Public Health Service. At present it will be devoted to the treatment of soldiers, sailors, civil service employees, and members of the merchant marine.

Personal.—Dr. Wilbur A. Sellers, Montgomery, who suffered severe cuts and stab wounds in an affray, March 31, is reported to be out of danger.——Dr. Henry B. Wilkinson, has been elected city health officer of Montgomery, to fill the unexpired term of Dr. Carney G. Laslie, resigned.——Dr. Hill W. Howell, Hamilton, has been made health officer of Sumter County succeeding Dr. Benjamin N. Walker, Livingston, resigned.——Dr. Charles A. Mohr, Mobile, has been elected all-time health officer of Mobile County.

Epidemiologic Department Inaugurated.—A bureau of epidemiology is soon to be inaugurated by the state board of health. The work of this bureau will be to locate and trace to its source every epidemic of communicable diseases, to keep complete records of communicable diseases, and to have ready for instant reference at all times a full and comprehensive reference concerning all communicable diseases.——Dr. A. M. Collinson of Maryland has been invited to take charge of the work in Alabama, and Dr. William S. Keister of Roanoke, Va., has been appointed health director of sanitation. The state is being divided into five medical units containing from five to ten counties each, each district having a minimum staff composed of an all-time health officer, a rural school nurse, an inspector and a laboratory worker.

CONNECTICUT

Personal.—John W. Churchman, Major, M. C., U. S. Army, New Haven, professor of surgery in Yale University, has been named "Officier de l'instruction publique," by the French government in recognition of his service as physician in charge of French Military Hospital 32, bis, during 1916.——William Essex McGinley, Capt., M. C., U. S. Army, New London, on duty with the American Expeditionary Forces, had bestowed on him the military cross, by King George V, at Buckingham Palace, London, April 2.——Dr. David R. Lyman, Wallingford, who went to Europe as a member of the Rockefeller Commission for Prevention of Tuberculosis in France, has returned to this country.——William F. Verdi, Major, M. C., U. S. Army, New Haven, just returned after service in France, has been elected clinical professor of surgery in the Yale University School of Medicine.

DELAWARE

Personal.—Dr. Harrison M. Manning, Seaford, M. C., U. S. Army, who went overseas about two years ago and has been on duty in a base hospital in France, has returned home.——Dr. James P. Lofland, Milford, has been elected president, Evans Roberts, vice president, and E. P. Ruhl, secretary of the board of health of Milford.

State Board Appointments.—The governor announced, March 29, the following appointments to membership of the state board of health: Dr. William P. Orr, Jr., Lewes, and Dr. John W. Clifton, Smyrna (reappointed), and Dr. Edgar Bullock succeeding Dr. Abram E. Franz, term expired, and Dr. George W. K. Forrest, succeeding Dr. James A. Draper, all of Wilmington, resigned. Dr. Orr has been secretary of the board for about twenty years and president for several years past.

DISTRICT OF COLUMBIA

Lectures on Physical Anthropology.—Dr. Ales Hrdlicka, director of the division of physical anthropology, National Museum, is giving a series of lectures on physical anthropology in relation to medicine at the medical school of Georgetown University.

Changes in Contagious Disease Regulations.—As a result of conferences between the Committee on Contagious Diseases of the District Medical Society and the health officer, the contagious disease regulations will be so modified that practitioners will no longer be required to send in report cards in cases of diphtheria when the dagnosis has been confirmed bacteriologically by the health department laboratory. It has been arranged also that hereafter practitioners may report cases of scarlet fever and diphtheria as recovered when the clinical recovery is advanced sufficiently to warrant the discontinuance of professional attendance. Health department inspectors will thenceforward assume charge of the cases until the end of desquamation or the necessary negative cultures permit discharge from quarantine. Efforts were made to relieve physicians of the annoying obligation of sending reports of recovery from ailments like whooping-cough, chickenpox and measles, but since such recovery reports are specifically required by law only congressional action can change the situation. This is an illuminating example of the difficulties Washington labors under by reason of having the United States Congress for a city council.

Medical Society Activities.—The medical society of the District of Columbia will give a "get together" smoker on April 30. The members are rapidly coming back from the war and there is a general desire to renew the social contacts so long interrupted. It is hoped that Dr. John B. Deaver, of Philadelphia, will be the guest of the society on this occasion. The building committee of the society, having paid in full for a lot on M Street N.W., between Seventeenth and Eighteenth Streets, is vigorously moving toward the erection of a home for the organization. Building plans have been prepared and unanimously adopted by the society and the trustees have been authorized to proceed to build as soon as they think they have sufficient funds in hand. The plans call for a two story and basement structure, with provision for an auditorium, offices and committee rooms on the first floor; a reception or banquet hall, with serving room and cloak rooms on the second floor; and janitor's quarters, furnace room and coal bunkers in the basement. The Italian renaissance façade will be of Indiana limestone. It is estimated that the project will cost about $75,000 and the committee has already secured about 12 per cent. of the necessary amount before undertaking any campaign for further funds.

ILLINOIS

Rush College Commencement Date Advanced.—In order to permit attendance at the annual session of the American Medical Association, the commencement date of Rush Medical College has been advanced from June 11 to Friday, June 6.

Honors to Physicians.—The medical officers on duty at Camp Grant gave a dinner, April 2, in honor of the camp surgeon, George B. Lake, Col., M. C., U. S. Army, and Mrs. Lake, at which they were presented with a solid silver coffee service. The presentation speech was made by Frederick J. Combe, Major, M. C., U. S. Army, San Antonio. Colonel Lake has been transferred to take command of the Army General Hospital, Fort Benjamin Harrison, Ind.——Dr. Wladyslaw A. Kuflewski, Chicago, senior attending surgeon of St. Mary of Nazareth Hospital, was the guest of honor at the hospital on the occasion of the silver jubilee of his graduation. He was presented with a loving cup by Dr. Albert J. Ochsner, surgeon in chief, acting for the attending staff.

INDIANA

State Board Elects.—At the annual meeting of the state board of health held in Indianapolis, April 9, Dr. Hugh A. Cowing, Muncie, was elected president, and Dr. John H. Hewitt, Terre Haute, vice president. Dr. John N. Hurty, Indianapolis, was reelected secretary.

Infectious Diseases.—From Muncie it was reported, April 12, that although there had been at least 200 cases of influenza at the end of the week, the epidemic was on the decline so that on the date mentioned there were not more than fifty cases in the city. At Anderson, April 12, it was said by the county superintendent of schools that only eighty-four out of 289 eighth grade pupils had passed the examinations for promotion, owing to the great loss of time on account of influenza. At Kokomo, April 11, it was reported that influenza was responsible for seventy deaths during March. The highest previous record was in December, when it was fifty-six. Whiting has had two cases of lethargic encephalitis. In Indianapolis there had been two deaths from encephalitis, as reported April 10.

Personal.—Frank B. Humphreys, Major, M. C., U. S. Army, Angola, recently discharged from duty, has been promoted to lieutenant-colonel, M. C., dating from Nov. 11, 1918.——Dr. James T. Biggerstaff, Wabash, health officer of Wabash County, has won his contest with the board of county commissioners, which had attempted to remove him from office in January. The board had declared the office vacant and had made charges of malfeasance in office, which later were dropped by the board. Dr. Biggerstaff's claim for salary for the period has also been allowed.——Dr. Harley H. Miller, Galveston, is seriously ill with septicemia following an infection of the hand.——Larue D. Carter, Lieut.-Col., M. C., U. S. Army, Indianapolis, who is on duty with the American Expeditionary Forces in France, has been promoted to colonel, M. C.

MARYLAND

Annual Meeting of Medical and Chirurgical Faculty.—The one hundred and twenty-first annual meeting of the Medical and Chirurgical Faculty of Maryland convened, April 22, and continued in session until April 24. With the exception of the final sessions Thursday, the meetings were held in the Faculty Hall, Baltimore. The last sessions were held at the Johns Hopkins Hospital and at U. S. Army General Hospital No. 2, Fort McHenry.

To Fight Narcotic Evil.—The Maryland Board of Pharmacy, at a recent meeting, resolved to take such action as would prevent the spread of the narcotic drug evil in Maryland, and, so far as possible, to get at the sources of supply and prevent the illegal traffic of such drugs as cocain, morphin and heroin, and to cooperate with the police authorities of the state and apprehend all physicians, pharmacists and others who are illegally prescribing, dispensing and dealing in these dangerous drugs. The board believes that the drug evil is not so serious in Maryland as in other states, and that the enforcement of all state narcotic legislation should be in the hands of the board of pharmacy in active cooperation with the various police departments of the state, and the United States Revenue Department in the enforcement of the Harrison Narcotic Law. The Maryland board already has adopted a regulation covering the professional status of a pharmacist as to the use of narcotic drugs, in that an applicant for registration is compelled to furnish with the application a signed affidavit by two persons, preferably pharmacists in good standing, that the applicant is not in any way addicted to the use of narcotics. The regulation is being vigorously enforced and each application is investigated before action is taken. This precaution is to protect the citizens of the state from unscrupulous venders of these dangerous drugs.

MINNESOTA

Personal.—Erling W. Hansen, Capt., M. C., U. S. Army, Minneapolis, on duty with the Army of Occupation, has been decorated with the Croix de Guerre with a gold star. While in charge of Ambulance Company No. 12, and attached to the 18th Regiment, he displayed unusual coolness and courage, remaining in an exposed dressing station until all the wounded had been dressed and sent to the rear.——Richard O. Leavenworth, Lieut., M. C., U. S. Army, Glencoe, who had been located in the St. Mihiel sector, has been sent to the University of Nancy, France, for special surgical study.

NEW YORK

Personal.—Dr. Clive E. Hallenbeck, Dunkirk, has been placed in charge of the venereal disease clinic which is to be opened in that city, May 1.——Drs. Clarence L. Hyde, Horace LoGrasso, and Harry J. Bendes of the J. N. Adams Memorial Hospital, Perrysburg, conducted a public health clinic at Gowanda, April 11. This was the first of a series of clinics to be held in Cattaraugus County under the auspices of the Tuberculosis Committee of the State Charites Aid Commission.——Dr. Isaac W. Brewer, Geneva, has been apponted full-time health officer of Watertown.

Public Health Activities.—Sufficient funds have been promised to secure the services of expert diagnosticians for two tuberculosis clinics which will be held each month for one year, at Plattsburg.——The local Red Cross Chapters in Waverly and East Rochester have utilized Red Cross funds for the employment of public health nurses.——A health survey of the Tonawanda Indian Reservation is being made by Mrs. Elizabeth N. Finnegan, who previously made a similar survey of the Onondaga Indian Reservation.——The trustees of the village of Potsdam have engaged a public health nurse.——The Onondaga Indian Reservation has employed a visiting nurse who, in addition to her regular duties is planning a social center for young women and aiding in the distribution of clothing to families in need.——The Cayuga County board of supervisors has appropriated $5,000 for the establishment of a county laboratory at Auburn.

New York City

Personal.—Lieut.-Col. Burton J. Lee has been cited for exceptionally meritorious and distinguished services as surgical consultant attached to the Second Division. He served continuously at the front, and displayed unusual ability in directing surgical teams which cared for hundreds of wounded soldiers at a time when adequate hospitalization could not be established.

Dinner to Colonel Lambert.—A complimentary dinner was tendered Col. Alexander Lambert, M. C., U. S. Army, President-Elect of the American Medical Association, by his professional friends in New York City on Saturday night, April 12, at the new Commodore Hotel. About 400 of the leading physicians of New York and the East attended. Dr. George D. Stewart acted as toastmaster. The speakers were Col. Frank Billings, M. C., U. S. Army, Chicago; Dr. William S. Thayer of Baltimore, formerly Brigadier-General, M. C., U. S. Army; Dr. George E. Brewer of New York, formerly Lieutenant-Colonel, M. C., U. S. Army, and Rev. Charles A. Eaton of New York. Dr. Lambert responded with an account of his experiences abroad as chief medical director of the American Red Cross hospitals.

The Drug Campaign.—Health Commissioner Copeland has made a formal protest to the prison commission that convicts in state institutions are receiving an uninterrupted supply of narcotic drugs. Another serious matter brought to the attention of the health commissioner is that a considerable number of transportation employees are drug addicts. According to Commissioner Copeland, the state narcotic commission has not yet taken steps toward remedying the situation over which it has sole control. The commissioner has offered the narcotic drug commission offices and clerks in the department of health building, as no appropriation was made for offices for the commission in this city. The announcement is made that no more clinics for the treatment of drug addicts will be opened by the health department at present and that the work will be confined to that of the Worth Street Clinic. Dr. Copeland emphasizes the necessity for physicians to continue prescribing for drug addicts with a view of effecting a cure. Walter R. Herrick has been appointed chairman of the state narcotic drug commission. Statistics based on the histories taken from 214 drug addicts coming to the clinic show that most of them are unskilled workers. Thirty-four different pursuits are represented. At least 20 per cent. of the addicts are engaged in transportation work. Among this number were four physicians, one newspaper man and a schoolteacher.

OHIO

Trachoma Threatened.—There are reported to be more than 500 cases of chronic infection and inflammation of the eyes in the city of Portsmouth, and Dr. William S. VanFossen of the state board of health considers the situation sufficiently grave to require prompt and decisive action. This may necessitate medical inspectors and attending nurses in schools and the establishment of a clinic for further treatment.

Correction.—Information has been received from the secretary of the state medical board that the item which appeared in The Journal, April 12, p. 1089, relating to the Talley bill is incorrect, explaining that the Talley bill is an amendment to the medical practice act of Ohio, and gives mayors' courts, police courts and justices of the peace final jurisdiction, and that it is general in its application, applying both to medical and to limited practitioners.

Personal.—Aretas E. Biddinger, Asst. Surg., Lieut., M. C., U. S. Navy, Cleveland, has been recommended for the Distinguished Service Order.——Dr. John W. McKemy, Capt., M. C., U. S. Army, who has been on duty with the American Expeditionary Forces in France and who was cited by Major-Gen. John O'Ryan for gallantry under fire, has been discharged from the service and returned to his home.——Dr. George R. Wiseman, Amherst, who is on duty in Palestine, has been assigned to take charge of the hospital at Damascus.

Illegal Practitioners.—Laura May, Columbus, is said to have been placed under arrest at Yellow Springs, April 2, on the charge of practicing medicine without a certificate. The affidavit against Dr. May charges her with illegally practicing medical healing in the case of the 7 year old child of John F. Bock, Montgomery, who is a sufferer from organic heart trouble.——Charles H. Ross, Youngstown, is said to have been arrested on orders of agent of the state health department charging him with practicing medicine without a license or certificate from the state medical board, and representing himself as being a licensed physician. He was sentenced to three months in the county jail and to pay a fine of $300 and costs.

PENNSYLVANIA

Health Department Summer Camps.—Dr. Edward Martin, state commissioner of health, has arranged for a series of summer camps for the medical inspectors of his department with the idea of extending them for other attachés of his department. The county medical inspectors will be required to attend the camps, where instruction in sanitation and specialized lines will be given.

Hospital Units Return.—Sixteen medical officers of U. S. Base Hospital No. 27, the University of Pittsburgh Unit, after more than eighteen months' service overseas, reached Pittsburgh, April 4.——Base Hospital No. 10, the unit organized by the Pennsylvania Hospital, landed in New York, April 17. This unit left this country in May, 1917, with twenty-seven officers, sixty-five nurses and 165 enlisted men. It returns with twenty-eight officers, eleven of whom were with the original unit, and 168 men. At Tréport, France, it handled 48,800 cases; during the second battle of Ypres, in August, 1917, and in March, 1918, the unit's limit was severely taxed. The unit was cited on two occasions by the British high command. The first citation was in September, 1917, and the second in March, 1918.

Personal.—In celebration of forty continuous years of service on the staff of the Dixmont Hospital for the Insane, thirty-five years of which were spent as superintendent, a reception was tendered Dr. Henry A. Hutchison by friends and employees, at Dixmont, April 15.——Fred H. Bloomhardt, Lieut.-Col., M. C., U. S. Army, Altoona, has been selected by the general staff of the army in France to take a postgraduate course in medicine at the Sorbonne, Paris.——Dr. Maurice T. Leary, Ridgway, secretary of the Elk County Medical Society, has been appointed county medical inspector for the department of health.——Dr. John L. Marchand, Irwin, has returned from Prinzapolka, Nicaragua, Central America, where he has been for several years.——Edward R. Plank, Major, M. C., U. S. Army, Carlisle, one time secretary of the Cumberland County Medical Society, is now commanding officer of the 316th Field Hospital, American Expeditionary Forces.——Dr. John N. Sprowls, Claysville, was seriously injured when his automobile went over an embankment near Taylorstown, February 27. His left hip was fractured and left knee lacerated. He is under treatment in the City Hospital, Washington.

Philadelphia

Qualify for Medical Inspectors.—Twenty-one physicians in a class of thirty have qualified for the position of assistant school medical inspector, bureau of health.

Public Health Day.—A public health day has been set for April 30. It will be conducted under the auspices of the department of public health and charities, College of Physicians, Child Federation, county medical society, and Babies Welfare Association. The meeting will be held in the William Penn High School. The speakers will be: Dr. Edward Martin, commissioner of health for Pennsylvania; Dr. S. Josephine Baker, director of the Bureau of Child Hygiene, and Dr. Wilmer Krusen, director of the department of health and charities.

Babies Hospital Contract.—The contract for the Babies Hospital, to be erected at the northeast corner of Delancey Place, has been awarded. The building is to be eight stories in height, and fireproof. The Babies Hospital in Philadelphia was established in June, 1911, and was incorporated under the laws of Pennsylvania, to provide 'for the treatment and care of sick babies and in connection therewith, to instruct and train suitable persons in the duties of caring for babies; to institute plans for the study, prevention and cure of disease of early life."

VIRGINIA

Object to License Tax.—Physicians and dentists of Norfolk, it is said, are planning to discontinue free service in various departments of the city government through the health department, following the assessment of a license tax against the professions. The tax proposed by the ordinance is $25, and 1 per cent. of all income over $2,000. In [illegible] claim for tax exemption, physicians [illegible] that at least $200,000 in gratuitous serv

New Sanatorium to Be Established.—A new sanatorium for the treatment of pulmonary tuberculosis is to be established at Charlottesville during the summer by the state board of health. This will be the third tuberculosis sanatorium to be built by the board, the others being at Catawba and Burkeville. The state board of health and the University of Virginia Department of Medicine plan to affiliate in the conduct of the sanatorium, the students of the medical school serving in rotation in the sanatorium, and the nurses for the institution being supplied from the university hospital training school. It is expected that the institution will open next autumn, as soon as buildings capable of housing 100 or more patients are completed.

WISCONSIN

New Officers.—At the annual meeting of the Marinette County Medical Society held in Marinette, March 28, Dr. John W. Boren was elected president; Dr. Alexander T. Nadeau, vice president, and Dr. Luella E. Axtell, secretary-treasurer.——The Fox River Valley Medical Society at its annual meeting held in Fond du Lac, March 11, elected Dr. R. H. Purdy, Appleton, president. Green Bay was selected as the next place of meeting.

Personal.—Clarence C. Del Marcelle, Lieut., M. C., U. S. Army, city physician of Neenah, who has been on duty in the American Expeditionary Forces, has been awarded the Croix de Guerre for bravery while attending wounded men under fire.——Dr. William L. Holt, health officer of Beloit, who has been ill with scarlet fever, is convalescent, and has resumed his duties.——Dr. Walter A. McEachern, M. C., U. S. Army, Superior, has been elected president of the Superior Medical Officers of the World's War.——Dr. Joseph N. Aubin, Peshtigo, is under treatment in St. Joseph's Hospital in Menomonie, for pleurisy.

CANADA

Defeat of the Osteopath Bill.—The *Bulletin Médical de Québec* remarks, "As we might have foreseen, the osteopath bill has been again rejected by our legislators. It did not even succeed in getting into the legislative assembly, and the efforts for it had to be restricted to an attempt to influence the committee on private bills."

The Quebec Medical Society.—This medical society seems to be displaying a new burst of energy which arouses the expectation of important works. The next meeting is to be held in new quarters and in a new part of town. The *Bulletin Médical de Québec* comments that it is hoped that this new start will aid in drawing the members of the profession closer together for mutual stimulation and production of works which may in time form an important nucleus for medical progress. "It is a duty for us all in this after-the-war period to aid in this work of reconstruction and development."

GENERAL

Roentgenologists to Meet.—The midsummer meeting of the Western Roentgen Society will be held in Cleveland, June 5 and 6, under the presidency of Dr. Oliver H. McCandless, Kansas City, Mo.

Women Physicians Establish Hospitals.—The Medical Women's National Association, New York, has established and is maintaining four hospitals in France and one in Serbia, and has sent more than 100 women physicians to service in Europe.

Red Cross in Serbia.—Nineteen American women physicians are now in the Balkans, assisting the American Red Cross in its work of caring for the sick and destitute. These physicians are from the American Women's Hospital at New York and are located in Serbia, Montenegro and Albania. In Serbia, where the most sickness and destitution exist, the following women physicians are at work: Drs. Marjorie B. Burnham, Ashtabula, Ohio; Mary H. Elliot, New York; Harriet M. Gervais, Dorchester, Mass.; Alberta M. Greene, Judith Bay, Mont.; Lulu Peters, New York; Marion C. Stevens, Reading, Mass.; Regina Flood Keyes, Buffalo, and F. Mabel Flood, Elmira, N. Y. Dr. Katherine M. Cook, Washington, Pa., and Dora E. Bowman, Kansas City, Mo., are assisting the American Red Cross physicians in Montenegro; and Drs. Nell G. W. Bartram, Huntington, Pa.; Mary J. Hyndman, Philadelphia, and Sarah E. Foulks, Burlington, N. J., are doing similar work in Albania.

Miss Delano Dies.—Miss Jane A. Delano, who died, April 15, aged 56, at Base Hospital No. 8, at Sauvigny, France, was one of the foremost figures of the nursing world. Under her direction more than 30,000 nurses were recruited through the American Red Cross for service with the Army and Navy after the United States entered the great conflict. Miss Delano graduated from Bellevue Hospital, New York, in 1886, and two years later volunteered to nurse yellow fever victims in Jacksonville, Fla. Although at that time medical science had not decided that the mosquito was a yellow fever carrier, Miss Delano had reached that conclusion, and had insisted on the use of mosquito netting by her nurses with the most satisfactory results. In 1891 she was made superintendent of the nurses' training school of the University of Pennsylvania, a position she held for five years, and in 1900 she returned to Bellevue Hospital to direct the nurses' training school there, continuing in the capacity until 1905. When the American Red Cross, following the final reorganization in 1906, entered into an agreement with the American Nurses' Association for the purpose of developing a nursing reserve for the Army Nurses Corps, Miss Delano was appointed chairman of the committee in charge of the work. She was also named as superintendent of the Army Nurse Corps by the Surgeon-General, in which capacity she visited the Philippine Islands, China, Japan and Hawaii.

Conference on Hospital Standardization.—On Monday, April 21, at the headquarters of the American Medical Association, Chicago, a conference was held of representatives of eight organizations interested in the development and standardization of hospitals. The organizations and their representatives are as follows: American Medical Association, Dr. Arthur Dean Bevan; the American Hospital Association, Dr. A. R. Warner; the American College of Surgeons, Col. Franklin H. Martin; the Association of American Medical Colleges, Dr. Fred C. Zapffe; the Catholic Hospital Association, Dr. B. F. McGrath; the American Nurses' Association, Miss Clara D. Noyes; American Association of Hospital Social Workers, Miss Edna G. Henry; Federation of State Medical Boards of the United States, Dr. Walter L. Bierring. Others present were Dr. S. S. Goldwater, director of Mount Sinai Hospital, New York; Dr. John M. Dodson, dean of Rush Medical College; Dr. N. P. Colwell, secretary of the Council on Medical Education of the American Medical Association, and Miss M. H. McMillan, principal of the School for Nurses of the Presbyterian Hospital.

It was decided to organize an American Hospital Conference to be made up of two representatives of each of the organizations above named and two each also from the American Association of Industrial Physicians and Surgeons and the medical departments of the United States Army, Navy and Public Health Services, altogether twenty-four members. An executive council of three members was created to have in charge the formulation of standards, constitution and other essentials which will be presented at the first meeting of the conference which it is planned will be held in connection with the annual meeting of the American Hospital Association in September. A second meeting will be held in connection with the annual conference of the Council on Medical Education to be held in Chicago in March, 1920. The members appointed on the executive council were Dr. A. R. Warner, chairman, Cleveland; Dr. John M. Dodson, Chicago, and Dr. Walter L. Bierring, Des Moines, Iowa. It is believed that through this hospital conference any standards prepared for the measurement of hospitals will meet the needs of all the various factors now interested in the development and standardization of hospitals.

FOREIGN

The Helmholtz Medal.—The German Helmholtz medal has been awarded this year to Roentgen.

The German Casualties During the War.—The *Deutsche medizinische Wochenschrift* of Dec. 26, 1918, stated that the latest official figures place the casualties at 1,600,000 killed, including 58,500 officers; 20,300 missing; 618,000 severely and 4,164,000 less severely wounded.

Deaths in the Profession Abroad.—**L. Mohr**, professor of internal pathology at the University of Halle, author of works on metabolism.——**Dr. T. Jaffé**, at Frankfurt a. M., aged *69.* ——**Dr. R. Semon**, professor of anatomy at the University of Jena, author of a well known work on the memory, aged 60.——**Dr. H. Fischer**, formerly professor of surgery at the University of Berlin, aged 88.

Miyajima Doing Research Work in Brazil.—The *Japan Medical World* states that Professor Miyajima of Tokyo has arrived in Brazil where he is to do research work at the Butantan Institute, the free use of which has been granted him by the public health authorities. This institute specializes in the preparation of antiserums and antivenins.

Miyajima's research on Japanese river fever, in collaboration with Professor Kitashima, was recently mentioned in The Journal, p. 1115.

Physicians in German Legislative National Assembly.—Only one physician, Dr. Hartmann, was elected to the National Assembly in Germany, but three physicians represent the profession in the Prussian Assembly. They are Abderhalden of Halle, Schlossmann of Düsseldorf and Struve of Kiel. Mugdan, who for many years has been the valiant representative of the profession in the reichstag, was a candidate for election but was defeated, as also was a woman physician candidate.

Personal.—Norman Cecil Rutherford, Lieut.-Col., R. A. M. C., England, has been ordered to be detained as insane in his trial for the killing of Miles Charles Seton, Major, R. A. M. C., of Melbourne, Australia, January 13.——Dr. Elizabeth E. Leonard, dean of Union Medical College, and superintendent of Douw Hospital, Peking, China, spoke before the Presbyterian Society in Seattle, April 8. Dr. Leonard has been in China since 1895 and expects to return to her work in July. The hospital with which she is connected cares for about 8,000 patients a year.

Too Many Medical Students in Austria.—The *Deutsche medizinische Wochenschrift* relates that 1,000 students registered for Professor Tandler's course in obstetrics, at Vienna, and another professor of obstetrics had quite a large registration. Tandler appealed to the students for most of them to abandon the idea of a medical course and take up another career, preferably farming. He declared that there would be no room for so many physicians in Austria, and that probably physicians from Austria would not find a ready welcome in other countries for the next few years at least. There are about 4,000 medical students enrolled, a fourth of them from Galicia. He protested that some limit must be imposed.

Proposed Consolidation of Danish Medical Societies.—After prolonged discussion, the Copenhagen Medical Society recently voted, with only two dissenting voices, in favor of the formation of a Danish Medical Association to consolidate the medical societies of the country and the specialist societies, and to accept the offer of the owner and editors of the *Hospitalstidende* to hand over that journal to the new general association. The Copenhagen Medical Society has a record of 125 years of work, and was for many generations the center of scientific activity for the whole country. The trend of the times has brought into existence independent medical societies at other points, and each group of specialists now has its own society; but the profession now realizes the importance of organization and cooperation on a country-wide scale, and delegates from the existing societies have been discussing the proposed merger for some time. The *Hospitalstidende* is owned by Prof. T. Rovsing who offered to turn it over for five years to the proposed new Danish Medical Association. The other Copenhagen medical weekly, the *Ugeskrift for Læger,* is the organ of the Almindelige Danske Lægeforening. Both have been indexed regularly in our Current Literature Department since its foundation as taking high rank among the representative medical journals of the world.

Conference of Italian Medical School Inspectors.—The *Policlinico* relates that the medical school inspectors of the principal cities of Italy met recently at Bologna under the auspices of the Italian Association for the Hygiene of Schools. The addresses and discussions emphasized the necessity for educating the public to the idea that the school is the pivot for all action for the hygienic uplift of the nation. Resolutions were passed urging the adoption of medical school inspection for all schools throughout the country, and a course of training in pedagogic hygiene for all candidates for teachers of every grade, from the lowest to the highest. It was decided to publish a pamphlet on school hygiene in its minutest details, to be sent to all health officers, school principals and school inspectors, etc., and another pamphlet more popularly worded will be distributed among the teachers. The American Red Cross has promised its cooperation in this line. The Italian Association for the Hygiene of Schools has a permanent office in charge of Prof. M. Ragazzi, via Baldi, No. 15, Genoa, Italy, and it asks for suggestions of all kinds on ways and means to promote hygiene, and reports on what has been already accomplished at various points in the line of hygiene in and outside of the school, training in hygiene, etc. The Italian government has already organized a series of five lectures on practical hygiene to be delivered in all the normal schools of the country by university lecturers.

LONDON LETTER

London, April 2, 1919.

The American Red Cross in Great Britain

An account of the work of the American Red Cross in Great Britain compiled by Capt. C. D. Morris, the director of information attached to the American Red Cross in this country, makes an interesting story of difficulties overcome and efficient organization. At the opening of 1918, the only hospital beds available for American soldiers were in two or three American Red Cross hospitals which were then being used for British troops. The influx of Americans was only just beginning, and the Army Medical Service and the Red Cross together bent themselves to the task of providing adequate accommodation for hospital cases. All the American hospitals were directly in charge of the United States Army or Navy medical authorities. The assistance of the Red Cross was called on in cases in which the army and navy supply department found itself unable, for any reason, to meet the requirements of the men, or in case of sudden emergency. The function of the Red Cross hospital department became, therefore, largely that of a supply and equipment organization, and this function was exercised through members of the Red Cross personnel acting in conjunction with, and more or less under the direction of, the army medical authorities. Practically no plans for any extensive hospital organization in Great Britain were thought necessary until the German spring offensive brought about a sudden decision to bring large numbers of American sick and wounded to England. With the decision to brigade American troops with the British, an entire revision of the plans for hospital work became imperative, for now Americans from the front were expected to come to England in large numbers. In the meantime, the number of American troops that were being transported by way of England had increased beyond all expectations, and large increases in the corresponding hospital accommodation became necessary for their needs. In addition, the possibility of an epidemic had also to be kept in mind. A considerable number of pneumonia cases were expected from the transports during the autumn, and plans were made accordingly; but the enormous number of serious cases which accompanied the outbreak of influenza on the transports swamped all the hospitals and tested to the utmost the army medical service.

The general scheme of hospital construction adopted by the army in the early summer of 1918 provided for a total of about 25,000 beds before the end of the following winter. Of this number, the ten American Red Cross hospitals for soldiers (excluding the two naval hospitals and the nurses' convalescent home) would have provided about 5,500 beds if the plans for construction had not been broken off by the armistice. At this time the total number of beds available in Great Britain was about 9,770, of which 2,700 were in the ten American Red Cross hospitals. The largest number of Americans cared for at any one time in American hospitals in Great Britain was 9,310 (Nov. 12, 1918). The number of American soldiers cared for in British hospitals reached its maximum point, Oct. 30, 1918, when there were 5,584. Up to the end of September, the supply of American hospital beds in Great Britain generally exceeded the demand; but during October and November, it did not. This was due mainly to the influenza epidemic, and large numbers of influenza patients had to be sent to British hospitals. The influenza epidemic marked a separate epoch in the hospital problem in Great Britain. More than half the deaths among the American forces in Great Britain were due to this cause. The total number of cases during the period under review was 7,512. The number of deaths from pneumonia during the same period was 1,717. The total number of American soldiers who were patients in hospital in Great Britain during the year was 41,892. The high-water point of the American hospital records for the year came in October, when the influenza epidemic was at its height. During that month, 12,806 American soldiers were admitted to hospital in Great Britain. The army medical personnel engaged in the work of American hospitals in great Britain numbered, all told, about 3,200 persons, including 310 medical officers, 541 nursing corps, and 1,990 enlisted force.

The Prevention of Anthrax

In a lecture delivered at Bradford, Dr. T. M. Legge, government inspector of factories, dealt with the problem of anthrax prevention. He said that efforts had been made during the past forty years to control the danger to the operatives from anthrax in infected wool and hair coming from abroad. These consisted in attempting to remove dust by downward exhaust ventilation, separating out fallen fleeces and blood-stained material, and warning the workers of the need of early treatment, by means of illustrated placards showing the nature of the disease. Despite this, although the mortality rate had been kept down, the number of cases had increased, especially during the war. Thus, in the five years 1901 to 1905, ninety-eight cases were reported, including twenty-nine deaths; and in the five years 1914 to 1918, 242 cases and thirty-one deaths. Only two ways were possible for getting at the cause—either to prevent animals from contracting anthrax or to destroy the spores before fleece or hair was handled. No one could hope that the nomadic tribes in Central Asia would take steps to stamp out the disease in animals. Steam, while destroying anthrax spores, destroyed the wool for manufacturing purposes. Researches, however, carried out during the war at Bradford on behalf of the anthrax committee appointed by the Home Office, showed that wool containing highly infected blood clots could be rendered practically sterile by treatment involving, first, agitation for twenty minutes in warm water containing soap solution and a little sodium carbonate, assisted by squeezing through rollers, subsequent agitation of the wool with little blood adhering to it in a bath of warm water containing 2.5 per cent. formaldehyd, again assisted by squeezing through rollers, and finally drying in a heated current of air. Already steps are being taken to establish a trial disinfecting station in this country, and to carry out the disinfection of the most dangerous materials. Ultimately it is hoped that the disinfection will be carried out under British control in the place of export of infected material.

Health and Occupation

The agitation of the miners for increased wages and shorter hours of work has been carried out with a good deal of exaggeration as to the danger and unhealthfulness of their work. In a letter to the *Times*, Prof. J. S. Haldane corrects this widespread mistake as to the dangers to life and health in coal mining as compared with other occupations, and gives the subjoined table, compiled from the last of the reports on occupational mortality issued by the registrar-general. The figures are for ages from 15 to 55, the death rates for older persons being unreliable on account of imperfections in the census entries. For purposes of comparison various occupations are included.

DEATH RATES FROM ALL CAUSES PER THOUSAND LIVING IN EACH AGE PERIOD

	Age Period			
	15-25	25-35	35-45	45-55
All occupied and retired males	3.5	6.3	10.9	18.7
Occupied and retired coal miners	3.8	5.1	8.0	15.2
Occupied and retired barristers and solicitors	...	4.9	7.6	13.8
Occupied and retired shopkeepers	3.1	5.6	9.4	16.4
Occupied and retired physicians	...	5.6	10.6	18.5
Occupied and retired farm workers	2.4	4.3	6.4	11.2
Occupied and retired merchant seamen	9.6	13.9	19.8	29.6

Among coal miners the death rate from accident is about double that in average occupations. Even so, coal mining is a relatively safe occupation. It has become so to a steadily increasing extent during the last forty years. Apart from accidents, it is now one of the most healthful occupations, though it could be made still more healthful and considerably safer.

MEXICO LETTER

Mexico City, April 13, 1919.

Lethargic Encephalitis

News has been received from the cities of Monterey and Merida that some cases have been observed there which it is believed may be lethargic encephalitis. Although the news has not been confirmed, as the notice came from newspaper correspondents, yet it has not failed to excite some alarm. The public health authorities have not made any statement on the matter. If, as some think, the encephalitis has some relation to the epidemic of influenza, the fact is rendered probable by the extent of epidemic influenza in this country during the preceding months. If, on the other hand, the encephalitis is regarded as an anatomic variety of poliomyelitis, then it would be more difficult to explain, as the latter disease is only exceptionally seen here.

Smallpox

The state of Oaxaca is now taking its turn among the states where smallpox is developing in epidemic form. As part of that state has withdrawn from allegiance to the Central Government, it is feared that the disease may cause more ravages there than in other regions.

Visitors from the United States

Within the last month we have received the visits of different parties who have come from the republic north of us for the purpose of linking closer together the two countries. One group came from San Antonio, Texas, others from the Mississippi Valley, and the last party from Dallas, Texas. All were very cordially received and entertained, all expressed very favorable opinions of Mexico, and emphasized the necessity for establishing durable harmony between the two neighbors "which are neighbors by a geographic fatality which nothing nor no one can change." I appreciate the truth of the remarks of the visitors, their good faith and their good wishes, but as all the visitors so far have been mostly merchants, I assume that the relations which they are promoting are commercial relations. But, if the wish is to have the two peoples actually fraternize—which is what the cultured and liberal persons here desire—then there must be a work of propaganda of culture, sending to Mexico university professors, preferably those that can talk Spanish or French; there must be efforts made to increase the emigration of students to the United States and of Mexican professional men to the United States to take postgraduate courses, and there must be efforts made to promote the study of Spanish beyond the Rio Grande and of English on this side of it. Much has been said recently of the interchange of university professors and students between the two nations—and I have made myself the echo of the notices of this kind that have been sent out—but it is certain that to date, so far, there has been nothing but a series of beautiful prospects. Only one single concrete fact has been realized to date in this "getting together" on a higher plane than mere business, and this one concrete fact is the appearance of the Spanish edition of The Journal. This has had results, but the medical profession is not a leading force except in a few matters.

Personal

Among the recent deaths in the profession in Mexico are those of Dr. Delfino Victoria, who was governor of the state of Veracruz; Dr. N. San Juán, retired from practice for twenty years, the first incumbent of the chair of gynecology in the medical faculty here, and Dr. Domingo Orvañanos, formerly professor of clinical medicine in the medical faculty here and later member of the National Public Health Board from 1877 to 1918. He was the representative of Mexico in various scientific congresses.

Dr. Pedro José Zepeda, a native of Nicaragua, but recently residing in New York, has arrived here and been cordially welcomed.——Dr. J. González Urueña has been appointed *consejero* of the University in place of Dr. Orvañanos.——Dr. M. Aveleyra has been added to the medical faculty here as *profesor libre* of medical pathology.

PARIS LETTER

Paris, March 13, 1919.

Healing of Fractures after Primary Suture

At a recent meeting of the Société de chirurgie de Paris, Dr. Pierre Duval reported 56 cases of war fracture which had been sutured primarily by Dr. Picot after proper surgical cleansing of the site of the fracture. The results obtained have been 3 pseudarthroses, 3 delayed unions and 50 unions, the parts involved and the time required being: 10 fractures of the forearm, one or both bones, twenty-three days; 21 fractures of the humerus, thirty-five days; 11 fractures of the legs, sixty-eight days, and 8 fractures of the femur, eighty-six days. The fractures of the arm and forearm healed as rapidly as do closed fractures of the same bones, but in cases of fractures of the bones of the lower extremities, healing did not take place as quickly. According to Dr. Picot, the reason for this was that fractures of the upper extremities were mobilized early, whereas those of the lower extremities were mobilized late. The conclusion arrived at is that these war fractures should be sutured as soon as possible so that they may be treated as closed fractures at the earliest date.

Picot made a radiographic study of these fractures treated by primary suture, and arrived at the conclusion that in the consolidation of a war fracture the bone alone is involved. There is no bloody effusion around the bone and no attrition of the soft parts, such as are found in ordinary simple fractures, as the contused muscles have been resected and the bloody effusion evacuated by filiform drainage; on the other hand, infection does not reach the seat of the fracture. Under these special conditions the consolidation is never exuberant, there is no large callus and no exostoses. The callus forms a cement which unites the two bone fragments and the consolidation occurs with the minimum of deformity.

Obligatory Physical Education

The national committee on physical education, sports and social hygiene recently held a general meeting under the presidency of M. Henry Paté. Propositions presented by Mérillon and Hélitas concerning obligatory physical education were adopted unanimously, and it was shown that much progress has been made in this direction. M. Paté extended thanks to General Pershing, who, in the name of the American army, recently constructed near the Vincennes Wood a stadium which will hold more than 10,000 persons. This stadium was erected at the expense of the Americans and will be given over to the use of France. Furthermore, the Franco-American Union has made known that as a token of its regard for France and to aid in welfare work in France, 300 Foyers du soldat have been built and will be maintained at the expense of the Union in various parts of France, and that they will in reality become 300 centers of physical culture. The city of Paris will establish forty playgrounds and four stadiums on the site of the fortifications which are to be demolished.

This national committee on physical education, sports and social hygiene has just organized new courses in social hygiene at the Musée pédagogique. These courses are to be on eugenics, maternity and physical and moral education; alcoholism; venereal diseases, syphilis and gonorrhea; infectious diseases and tuberculosis; dietetics, and industrial hygiene.

Encouraging Ambidexterity in Children

At the recent meeting of the Académie de médecine, Dr. Armaingaud pointed out the loss—military, civil and economic—which results from an artificial disability imposed on young children, and therefore on adults, in allowing them to use only their right hand, so that the left hand is used merely as an auxiliary to the right. Speaking from a military point of view, Armaingaud called attention to the statement made by General Baden-Powell, chief of a British Army Corps during the war, to the effect that no one could doubt the value of ambidexterity. If both hands were used equally by everybody, instead of being used only occasionally, or by a few persons, as is the case today, the strength of the army would be increased notably. Armaingaud also pointed out the advantages of the ambidextrous use of both hands in the practice of surgery and obstetrics, and related the case of a professor of surgery, who, while chief surgeon of an ambulance during the war, received a serious wound in his right hand, but who, nevertheless, continued to operate with his left hand, being ambidextrous. He also enumerated a considerable number of other professions in which ambidexterity would more than double the output.

At this time, when the population of France is decimated by tuberculosis and alcoholism, and when the excess of births over deaths is less each year, it is not a matter of indifference to permit the population of France to continue what may be called a physiologic mutilation, one which may be made to disappear at will. Armaingaud proposed to the academy (1) to issue an appeal to the people of France asking that the mothers, in the interest of the nation and in the interest of defense of the country, teach their children from the first to use both hands equally; (2) to request the minister of public instruction to make the equal use of both hands obligatory in all the primary and secondary schools; (3) to urge the foundation of a prize to be awarded annually to the teacher in France who has been most successful in carrying out this most desirable reform.

Marriages

Frank Barnes Long, Capt., M. C., U. S. Army, Sedalia, Mo., to Miss Anna Ruby Dillard of Jefferson City, Mo., in New York City, March 31.

John Joseph Gailey, Waterbury, Conn., to Miss Harriet Blanche C. Cowan of Chicago, April 6.

Thomas Floyd Leatherwood, Minot, N. D., to Miss Louise Smith of Buckingham, Que., August 13.

Deaths

Mortimer Frank ⊕ Chicago; University of Illinois, 1901; aged 44; died at his home, April 21, from cerebral hemorrhage. He was a graduate of the Massachusetts Institute of Technology; ophthalmologist to Michael Reese and other hospitals; a member of the American Academy of Ophthalmology and Oto-Laryngology; editor of the *Bulletin of the Chicago Society of Medical History;* especially known for his enthusiastic interest in medical historical subjects; the possessor of an extensive collection of medical historical books, correspondence and incunabula; the author of interesting studies on "Caricature in Medicine" and on "Early Ophthalmologic Surgeons," as well as of numerous other medical historic essays. He had recently completed a translation of Choulant's History of Anatomical Illustration which it is believed will be of great use to anatomists, artists and art schools.

William Henry Lane, Buffalo; University of Vermont, Burlington, 1913; aged 37; a member of the Medical Society of the State of New York; a captain in the Medical Corps in the 74th Infantry, N. Y., N. G., and recommended for commission as first lieutenant, M. C., U. S. Army; also a graduate of the dental department of the University of Buffalo; at one time resident physician at the Massachusetts School for the Feeble-Minded, Waverly; for five years professor of physiology, pathology and radiography in the dental department of the University of Buffalo; an expert in roentgen-ray work; died at his home, April 9, from acute bronchitis.

William Peter Faust ⊕ **Major, M. C., U. S. Army,** Schenectady, N. Y.; New York Homeopathic Medical College, New York City, 1895; aged 45; a member of the staff of Ellis and Mercy hospitals, Schenectady; for about twelve years surgeon to the American Locomotive Works, and health officer of Schenectady; who went abroad with the Schenectady Base Hospital, and afterward instituted base hospitals for the British government, his last assignment to duty being at Base Hospital No. 33, and who was honorably discharged from the Army, January 24; died at his home, March 27, from acute nephritis.

Alexander D. MacDonald, Galen, Mont.; McGill University, Montreal, 1887; aged 58; formerly health officer of Kallispell, and surgeon to the Flathead County Hospital, and Kallispell City Hospital; formerly president of the Flathead County Medical Society; thrice elected a member of the house of representatives and once speaker of the house; for the last four years superintendent of the Montana State Tuberculosis Sanatorium, Deer Lodge; died in that institution, April 6, from pneumonia.

William Henry Elliott, Savannah, Ga.; University of Virginia, Charlottesville, 1858; aged 82; chief surgeon of the Central of Georgia Railway, and Ocean Steamship Company from 1891 to 1913; assistant surgeon of the Savannah Volunteer Guard, and later of the First South Carolina Infantry, in the Confederate service during the Civil War; at one time president of the Medical Association of Georgia; for several years acting assistant surgeon, U. S. P. H. Service; died at his home, March 31.

William Asbury Hall ⊕ Minneapolis; Albany (N. Y.) Medical College, 1875; aged 65; once president of the Minnesota State Medical Association and Hennepin County Medical Society; a member of the surgical faculty of the University of Minnesota, Minneapolis; attending surgeon to St. Mary's and the Minneapolis City Hospital; consulting surgeon to the Northwestern Hospital; chief surgeon to the Minneapolis and St. Louis Railroad; died at his home, April 12, from cerebral hemorrhage.

Willis Sanford Hobson ⊕ Cleveland; Western Reserve University, Cleveland, 1898; aged 43; a specialist on diseases of the ear, nose and throat; assistant professor of histology in his alma mater, and assistant in medicine in the Lakeside Hospital Dispensary; visiting physician to the Children's Fresh Air Clinic; from 1915 to 1918 treasurer of the Cleveland Medical Association; died in the Peter Bent Brigham Hospital, Boston, April 5.

Stewart Donald MacKenzie, Edmonton, Alta.; McGill University, Montreal, 1901; aged 40; an officer of the Canadian Army Medical Corps; who had been in command of a military hospital at Brandshott Camp, England, and France;

⊕ Indicates "Fellow" of the A

and was discharged from the service in February; fell from the window of an apartment in New York City, March 27, and died from his injuries a few hours later in Bellevue Hospital.

Giles Hathcock ⊕ Lula, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1888; aged 57; professor of materia medica and therapeutics in the Hospital Medical College, Eclectic, Atlanta, and later professor of practice of medicine in his alma mater; for many years local surgeon of the Southern Railroad; died on a train between Lula and Atlanta, April 1, from cerebral hemorrhage.

Nathan Sidney Everhard ⊕ Wadsworth, Ohio; Western Reserve University, Cleveland, 1867; aged 78; local surgeon of the Erie Railway for many years; president of the Garfield Injector Company, Ohio Match Company, Ohio Salt Company, Ohio Boxboard Company, and Wadsworth Savings and Trust Company; who underwent operation at Mount Sinai Hospital, Cleveland, March 26; died, April 3.

Sheldon Guthrie Evans ⊕ **Capt., M. C., U. S. Navy;** College of Physicians and Surgeons, Baltimore, 1890; aged 49; a member of the Association of Military Surgeons of the United States; who entered the Navy, Nov. 18, 1890, and whose last station was at League Island Navy Yard, Philadelphia; died in Lankenau Hospital, Philadelphia, March 10.

Edward Marshall Hyland, Utica, N. Y.; Bellevue Hospital Medical College, 1883; aged 60; a member of the Medical Society of the State of New York; surgeon in charge of St. Elizabeth's Hospital; visiting surgeon to the Utica General Hospital, and physician and surgeon to St. Joseph's Infant Home and Maternity Hospital; died at his home, April 11.

Gustav A. Renz, St. Paul; University of Pennsylvania, Philadelphia, 1884; aged 58; also a graduate in pharmacy; pathologist to St. Joseph's Hospital; gynecologist to the City and County, St. Luke's and Norwegian hospitals; for fourteen years an official of the St. Paul Department of Health, and health officer in 1900; died at his home, April 13.

Joseph Bernard Monahan, New Haven, Conn.; Darthmouth Medical School, Hanover, N. H., 1894; aged 50; a member of the Connecticut State Medical Society; a specialist in tuberculosis; and for a time a member of the staff of the White Haven (Pa.) Sanatorium; medical inspector in the public schools; died at his home, March 23.

John W. Martin, New York City; New York University, New York City, 1880; visiting physician to the Northwestern Dispensary from 1882 to 1885, and attending physician from 1885 to 1886; died in a shooting gallery in Chicago, April 14, from the effects of a gunshot wound of the head, believed to have been self-inflicted, with suicidal intent.

William Wright Walcott ⊕ **Lieut., M. C., U. S. Army,** Natick, Mass.; Harvard Medical School, 1905; on duty with the 101st Engineers, American Expeditionary Forces, in France; formerly state inspector of health and later district health officer under the Massachusetts State Department of Health; died in France, March 16.

William LaFayette Cowper ⊕ **Lieut., M. C., U. S. Army,** Michigan, N. D. (license, North Dakota, 1898); aged 43; who after graduation from the Second Officers' Training Camp, Fort Snelling, Minn., was made surgeon on a U. S. Army transport; died in a hospital in Liverpool, March 9, from pneumonia.

Louis Constant Gobron, Rochester, N. Y.; Bellevue Hospital Medical College, 1888; aged 65; died in the Lee Hospital, Rochester, April 6, from the effects of poison, believed to have been self-administered, with suicidal intent, while despondent on account of illness and threatened blindness.

Joseph Cummings Poffenberger, Sunbury, Pa.; Jefferson Medical College, 1912; aged 31; a member of the Medical Society of the State of Pennsylvania; recommended for commission as first lieutenant in the Medical Reserve Corps, U. S. Army; died at his home, April 5, from pneumonia.

William Kirkpatrick Reid, Charlotte, N. C.; New York University, New York City, 1891; aged 51; a member of the Medical Society of the State of North Carolina; for several years city physician of Charlotte; died in the Presbyterian Hospital in that city, April 5, from septicemia.

Joseph Arthur Marchessault ⊕ Ashland, Wis.; University of Victoria College, Coburg, Ont., 1877; aged 67; health commissioner of Ashland; once president of the Ashland County Medical Society; died at his home, about April 1, from septicemia, due to an infected toe.

Phillip Rexford Waughop ⊕ Seattle; Harvard Medical School, 1894; aged 51; a specialist in urology; government physician and health officer in the Hawaiian Islands from 1900 to 1903; an authority on leprosy; died at his home, April 2, from pneumonia.

William Knisely Cherryholmes ⊕ Hamilton, Ohio; Bellevue Hospital Medical College, 1884; aged 58; a specialist in diseases of the eye, ear, nose and throat; died at the home of his nephew at Mansfield, Ohio, March 31, from pneumonia following influenza.

Thomas Milton Morrow, Altoona, Pa.; Baltimore (Md.) Medical College, 1898; aged 51; a member of the Medical Society of the State of Pennsylvania, and Altoona Academy of Medicine and Surgery; died in the Altoona Hospital, April 5, from uremia.

Claudius Edward Richard King, San Antonio, Texas; George Washington University, Washington, D. C., 1859; aged 79; a member and first president of the State Medical Association of Texas; a Confederate veteran; died at his home, March 14.

Galusha Burchard Balch, Yonkers, N. Y., and Richmond, Mass.; College of Physicians and Surgeons in the City of New York, 1860; aged 80; assistant surgeon of U. S. Volunteers during the Civil War; died at his home in Richmond, April 8.

Frank M. Fogle, Rowlesburg, W. Va.; College of Physicians and Surgeons, Baltimore, 1896; aged 44; a member of the West Virginia State Medical Association; director of the Rowlesburg Bank; died at his home, April 5, from pneumonia.

George W. Wroten, Louisa, Ky.; Pennsylvania Medical College, Philadelphia, 1861; aged 81; surgeon in the Confederate service during the Civil War; for ten years editor of the Big Sandy *News;* died at his home, April 9.

Paul Haddock Tracy, New York City; College of Physicians and Surgeons in the City of New York, 1893; aged 53; for many years a surgeon on transatlantic steamships; died in New York City, March 29, from heart disease.

James Madison Graham ⊕ **Lieut., M. C., U. S. Army,** Fruita, Utah; Medical College of Ohio, Cincinnati, 1902; aged 40; died in U. S. General Hospital No. 21, Denver, about April 6, from tuberculosis.

John T. Newhouse, Chesterfield, Ind.; Curtis Physio-Medical Institute, Marion, Ind., 1890; aged 71; a clergyman of the Christian Church for half a century; died at the Muncie (Ind.) Hospital, April 8.

Orizaba Manasco, Townly, Ala.; Birmingham (Ala.) Medical College, 1905; aged 36; a member of the Medical Association of the State of Alabama; died in a hospital in Little Rock, Ark., April 9.

Marcus Ernest Petersen, Brooklyn; Long Island College Hospital, Brooklyn, 1896; aged 47; formerly a member of the staff of the Bushwick Hospital; died at his home, April 7, from heart disease.

Jesse H. Lanam, Franklin, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1882; aged 71; died at the home of his niece, near Seymour, Ind., April 6, from cerebral hemorrhage.

Jacob Sampson Goldberg, New York City; Cornell University, New York City, 1918; aged 25; died in Mount Sinai Hospital, New York City, February 2, from staphylococcus infection.

Albert Alphonse Appel, Philadelphia and Haddon Heights, N. J.; Hahnemann Medical College, Philadelphia, 1898; aged 48; died in his office in Philadelphia, April 9, from heart disease.

Robert Arthur Gilliford, Olsburg, Kan.; Kansas Medical College, Topeka, 1899; aged 49; died at the home of his brother in Olsburg, March 13, from cerebral hemorrhage.

Frank A. Stickney, Kilbourne, Ohio; Columbus (Ohio) Medical College, 1880; aged 67; died at his home, March 25, from chronic nephritis.

William Henry Pulford, Delaware, Ohio; Cleveland University of Medicine and Surgery, 1894; aged 87; died at his home, January 16.

Ostrander C. Pollock, Shobonier, Ill.; Eclectic Medical Institute, Cincinnati, 1882; aged 79; died at his home, March 21.

Frederick Alfred Schlanger ⊕ Pittsburgh; University of Pittsburgh, 1909; aged 30; died in Atlantic City, N. J., about April 6.

David Andrew McCleary, Camden, Ind.; Rush Medical College, 1883; aged 62; died at his home, March 28.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

ANNUAL MEETING OF THE COUNCIL ON PHARMACY AND CHEMISTRY

The Council on Pharmacy and Chemistry, at its recent annual meeting, discussed at length the revision of New and Nonofficial Remedies and the problems of investigating proprietary articles, both of those voluntarily submitted to the Council, and also of those which the Council takes up on its own initiative. Other subjects of special interest to the medical profession, that were considered and acted on at this meeting, were:

Nonspecific Protein Therapy.—The Council decided to publish, at an early date, a report on the unscientific and commercial propaganda which is being conducted in the interest of establishing the use of therapeutic agents of this character. The Council believes that the profession should be warned of the specious and unproved arguments which are being circulated concerning the results obtained from preparations of this character.

Serums and Vaccines.—The Council appointed a committee to study the problems of serum and vaccine therapy. This, to the end that it might publish in THE JOURNAL for the information of the medical profession, the evidence obtainable regarding both the value of, and also the dangers incident to, the use of serums and vaccines. The study is to include (*a*) an exhaustive review of the literature; (*b*) a tabulation of the experiences of the Army and Navy as revealed in available official reports, and (*c*) a review of the data relative to these therapeutic agencies available in various clinics of scientific standing.

Hay Fever Pollen Extracts.—A special committee was appointed to study and report on the present status of pollen extracts in the prophylaxis and treatment of hay fever. This investigation is to include, especially, the rationale of the pollen protein mixtures now being advertised.

Supervision of Potent Drugs by the U. S. Public Health Service.—The Council adopted a resolution urging the enactment of a law by Congress which shall require the Public Health Service to extend its present work of testing the toxicity and efficiency of serums, vaccines, toxins, and antitoxins, to cover that of testing and standardizing other potent remedies that are used hypodermically or intravenously. The selection of such products as are a source of special danger to the public health, unless standardized and tested as to toxicity, would be left to the judgment of the Surgeon-General of the Public Health Service. Some of the preparations which might call for such standardization and testing are extracts of glands such as the pituitary gland, etc., and highly toxic drugs, such as arsphenamine, neoarsphenamine, digitalis preparations, etc.

Arsphenamine.—The Council passed this resolution: "That the control of the purity and potency of arsphenamine by the Public Health Service shall be continued after the conclusion of peace, and the control of the price be placed under an appropriate government agency."

Articles Described, But Not Accepted.—The Council has long recognized that there are proprietary preparations of therapeutic value which are so exploited as to be inadmissible to New and Nonofficial Remedies. The claims made for such preparations are unproved and, in many instances, are palpably false, and such claims and other violations of the rules of the Council make the acceptance of the products impossible. The Council decided to describe, for the information of physicians, articles of this character, and at the same time to give the reasons which stood in the way of including these preparations in N. N. R. The Council further requested that descriptions of articles of this character might be published in THE JOURNAL, and decided that these descriptions should later be published in a separate section of New and Nonofficial Remedies.

Cooperation in the Teaching of Pharmacology and Therapeutics.—A committee on Education was appointed to revive the pre-war work of the Council in establishing fuller cooperation between the Council and the teachers of therapeutics and pharmacology in medical schools. The object in view is that of bringing to the attention of third- and fourth-year medical students the therapeutic and pharmacologic problems which beset the young practitioner and showing the value of the Council's work in helping the profession to solve these difficulties.

Radium Water Therapy.—Another committee whose report should prove instructive and important is that appointed to investigate the present status of the therapeutic value of radium water therapy.

The following members of the Council on Pharmacy and Chemistry were in attendance:

C. L. ALSBERG, Chief of the Bureau of Chemistry, U. S. Department of Agriculture.

R. A. HATCHER, Professor of Pharmacology, Cornell University Medical College.

JOHN HOWLAND, Professor of Pediatrics, Johns Hopkins University Department of Medicine.

REID HUNT, Professor of Pharmacology, Harvard University Medical School.

HENRY KRAEMER, Professor of Pharmacognosy, University of Michigan, College of Pharmacy.

W. T. LONGCOPE, Bard Professor of the Practice of Medicine, College of Physicians and Surgeons of Columbia University.

G. W. MCCOY, Director of the Hygienic Laboratory, U. S. Public Health Service.

F. G. NOVY, Professor of Bacteriology, University of Michigan.

W. W. PALMER, Associate Professor of Medicine, College of Physicians and Surgeons of Columbia University.

W. A. PUCKNER, Secretary of the Council on Pharmacy and Chemistry and Director of the Chemical Laboratory of the American Medical Association.

L. G. ROWNTREE, Professor of Medicine, University of Minnesota.

G. H. SIMMONS, Chairman of the Council, and Editor of THE JOURNAL of the American Medical Association.

TORALD SOLLMANN, Professor of Pharmacology and Materia Medica, Medical Department, Western Reserve University.

JULIUS STIEGLITZ, Vice-Chairman of the Council, and Professor of Chemistry, University of Chicago.

W. A. PUCKNER, Secretary.

Correspondence

THE CADUCEUS AS A MEDICAL MOTOR CAR EMBLEM

To the Editor:—Since the American Medical Association abandoned the device of the Red Geneva Cross, because it rightfully belonged exclusively to the American Red Cross, in 1909, it was proposed to adopt a new emblem which would be distinctively medical. In 1912, the knotty rod and serpent of Æsculapius with the colors scarlet and gold were found to be the ancient inheritance of the physician. Notwithstanding this, in the advertising columns of THE JOURNAL, the caduceus of Mercury is offered to be used on the doctor's motor car. During the gasless Sundays of last fall a green cross was very largely employed to distinguish the physician and gave him the privilege of driving to his practice.

Possibly the fact that the enchanted wand of Mercury is used by the United States Army has misled some to think that it is the proper one to carry as the sign of medicine.

Mercury, the Roman god, is identical with the Greek god Hermes, and was considered the god of diplomacy, arts, sciences, commerce, gain and riches, especially of sudden and unexpected riches and of good luck at the games. He was usually represented with a purse in one hand, his magic caduceus in the other, and was supposed to preside over the commerce of the Romans.

The caduceus is an evolution of the staff of Hermes, which was an olive branch with garlands, for which the two serpents were substituted later in the position of coitus, meaning reproduction and increase, for without these the caduceus would be impotent. Then wings were added to indicate the speed of Mercury as a divine messenger, and became a symbol of power that produced wealth and was supposed to be the enchanted wand of prosperity. The words commerce, merchant, market and mercury all come from the same Latin root, *merx*, *mercis*, goods, and *mercor*, to traffic; hence, this wand is appropriately placed on delivery cars, railway trains and steamships.

Green is not a medical color but has long been carried by the hospital; therefore, the green cross means nothing to the physician himself.

In mythology, history and sacred scripture, man has always considered the serpent as representing power, wisdom and health. Twined about the knotty rod it was associated with the statue of Æsculapius at Epidaurus and became the earliest symbol of the healing art, as an expressive representation of power, support and protection in the difficult and knotty problems arising in the management of disease.

Scarlet and gold have always been regarded as characteristically medical colors. In the king's retinue, during occasions of state, the physician wore a scarlet cloak to distinguish him from the other professions. In the rural districts of Massachusetts a red flag was displayed from the farm house to notify the physician on his rounds that his services were required. In alchemy it is interesting to find that the philosopher's stone, when known as the elixir of life, was a red tincture, and as the key of wisdom, a red powder, and as a remedy for all diseases and to prolong human life, the alchemist mentions particularly a red stone.

Gold was spoken of by Gerber, the father of chemistry, who personified it as the "only pure and healthy man," and it was made the symbol of the sun, which orb had the greatest influence over disease.

These elements of the knotty rod and serpent, with scarlet and gold, have been embraced in the device of a simple emblem for the medical profession and accepted by the American Medical Association; hence, it is a mistake to persuade the doctor to wear a commercial badge, but he should be taught throughout the country, in the Army as well as in civil practice, to carry one correct and uniform design.

Further particulars and explanations can be found in The Journal, April 24, 1909, p. 325; the *Red Cross Bulletin*, July, 1909, p. 40, and *New York Medical Journal*, May 30, 1914.

Samuel P. Gerhard, A.M., M.D., Philadelphia.

[Comment.—It has been frequently contended that the wand of Mercury is not the proper symbol for the medical profession, as it has no medical significance; in fact, its adoption by the Army Medical Corps might be considered a reflection on the interest which we, as a nation, take in things classical. If the question is asked why the wand of Mercury was ever adopted as the symbol of the Medical Corps, the reply is rather difficult; surely not because the caduceus was used by Mercury *as conductor of the souls of the dead to the world below.* As pointed out by McCulloch (*Military Surgeon*, **41**:137 [Aug.] 1917), the emblem may have been borrowed originally from the Public Health Service, in which it had been used for many years. Churchill, the London medical publisher, used it on title pages two generations ago; but whoever recommended its use as a medical emblem in this country has either been conducted by Mercury, his titular deity, to join the souls of the dead in the world below, or is keeping unusually quiet.

However, the English are also said to have fallen into the same error. McCulloch tells us that the first use of the caduceus in medical heraldry was doubtless in the crest of Henry VIII's physician, the learned Sir William Butts—the same Sir William who appears in Shakespeare's drama of Henry VIII (V, ii, 11):

Cranmer [*Aside.*] 'Tis Butts,
The King's physician; as he past along,
How earnestly he cast his eyes upon me.

The Greek poets refer to Hermes or Mercury as giving sleep with the magic wand to whomsoever he chose; hence Milton calls the wand "his opiate rod," in Paradise Lost, xi, 133. Also Erasmus Darwin (grandfather of Charles Darwin) in Loves of the Plants, ii, 291, says:

So, with his dread caduceus, Hermes led
From the dark regions of the imprisoned dead;
Or drove in silent shoals the lingering train
To Night's dull shore and Pluto's dreary reign.

Such allusions as these may have given rise to the false conception of Mercury and caused the reader to suppose that if he could wave the "opiate rod" he could administer medicaments as well. Be that as it may, the first use of the caduceus by the Medical Department of our army was on the chevron of the uniform of the hospital steward, in 1856, although it was not employed by the medical officers until 1902.

As for the staff and serpent of Æsculapius: There is no doubt that this is a much more appropriate emblem for the medical profession than the wand of Mercury. It may be interesting to note that this emblem is now worn by the Royal Army Medical Corps.

Those who believe that preventive medicine is the crowning glory of the profession, as it certainly would seem to be, at this time, might prefer as an emblem, Hygeia (the goddess of health and the daughter of Æsculapius), surrounded by symbols representing her close companions—air, water, light, food, exercise, sleep, etc. Thus we should have the culmination of the trinity composed of Apollo, the sun-god and the very ancient god of medicine; Æsculapius, considered to be the son of Apollo; and the beautiful daughter of Æsculapius—Hygeia—at whose shrine perhaps more of the medical profession of today would be willing to worship than at the shrine of Æsculapius.—Ed.]

"THE NEEDS OF MEDICAL EDUCATION AS REVEALED BY THE WAR"

To the Editor:—I have read with a great deal of interest the article on medical education by Munson, in the last number of The Journal, and also an editorial and the letters of Vaughan and Munson, and I am writing to you to suggest that in any statistical study made by the Surgeon-General in regard to medical reserve officers it would be of interest to know:

1. The number of graduates of each medical school that were commissioned.
2. The number from each medical school that were discharged from the service prior to November 11, for any reason.
3. The number of graduates of every medical school living Nov. 11, 1918.

The first two items, of course, could only be supplied by the Surgeon-General's Office, while the latter, I imagine, could be readily supplied by The Journal if the Hollerith system was used for the directory.

The subdividing of the discharges under the head of different causes would be of interest, although, I believe, would give a mistaken impression, as there was a tendency I noted to "deal lightly" in regard to discharges, and thus many discharges for physical disability might well and properly have been included under other headings.

Gordon Wilson, M.D., Baltimore.

IDENTITY OF THE POPPY IN FLANDERS' FIELDS

To the Editor:—In the late Surgeon McCrae's poem "In Flanders' Fields," prominent mention is made of poppies in bloom, and local discussion has arisen as to whether they are of the variety that yields opium; and if so, whether there is not a deeper sense, almost therapeutic, in the words: "We shall not sleep though poppies grow in Flanders' field."

If this is *Papaver somniferum*, why is the world supply of opium drawn from Asiatic sources, and why may not the plant be cultivated successfully in America for therapeutic purposes? *Or was the allusion in the verses merely an* example of poetic license?

George Homan, M.D., St. Louis.

[Comment.—It seems possible that the line in MacCrae's poem "We shall not sleep though poppies blow in Flanders' fields" was written advisedly. No doubt the poppies that grow in Flanders' fields are *Papaver rhocas*, red poppy, or corn poppy. The capsules yield a milky juice, and an extract has been prepared having the properties of opium. The effect is very feeble, however, and the plant is of value mainly for its scarlet coloring matter.

The poppy which yields opium is *Papaver somniferum* and is generally believed to be a native of Asia Minor. It grows wild in southern Europe and even in England. It is successfully cultivated for its opium content in India, China, Japan, Asiatic Turkey, and other places. In Europe and the United States it is cultivated for its seeds, which yield a fixed oil. —Ed.].

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

RADIUM TREATMENT OF ARTHRITIS DEFORMANS

To the Editor:—Please give me the most recent information on the treatment of nodose rheumatism (arthritis deformans) by means of radium, and also the places to obtain this substance.

L. L. BIAMÓN, M.D., San Juan, P. R.

ANSWER.—According to New and Nonofficial Remedies, it has been claimed that radium emanation is of value in all forms of nonsuppurative, acute, subacute and chronic arthritis (syphilitic and tuberculous excepted), in chronic muscle and joint rheumatism (so-called), in arthritis deformans, in acute and chronic gout, in neuralgia, sciatica, lumbago, and in tabes dorsalis for the relief of lancinating pains. Its chief value is in the relief of pain. The relief of pain is well established; in consequence, improvement is sometimes observed; but curative results appear to be lacking. Due conservatism should be exercised in judging of the favorable reports published.

The following references may be consulted:

Rowntree, L. G., and Baetger, W. A.: Radium in Internal Medicine, THE JOURNAL, Oct. 18, 1913, p. 1438.

Chase, A. F., and Fine, M. S.: The Use of Atophan and Radium Emanation in the Treatment of Gout and Arthritis, THE JOURNAL, Sept. 12, 1914, p. 945.

McCrudden, F. H., and Sargent, C. S.: Influence of Radium Water Therapy on Creatinin and Uric Acid Metabolism in Chronic Arthritis, *Am. J. M. Sc.*, **156**: 702 (Nov.) 1918.

New and Nonofficial Remedies lists radium preparations prepared by the Radium Company of Colorado, Denver; the Radium Chemical Company, Pittsburgh; W. L. Cummings Chemical Company, Lansdowne, Pa.; Radium Ltd., U. S. A., New York, and Schieffelin & Co., New York. These companies may be addressed as to their available preparations for use in arthritis deformans.

"TREATMENT OF CHRONIC ASTHMA"

To the Editor:—In THE JOURNAL, March 8, 1919, p. 713, appears an article, abstracted from a foreign journal, in regard to the treatment of asthma with emetin hydrochlorid and sodium iodid. Will you kindly state what the minimum and maximum dose of sodium iodid intravenously should be? In the article referred to it is stated that the treatment is to be begun with 20 c.c., increasing to 120 c.c., but the strength of the solution is not given.

M. O. SHIVERS, M.D., Colorado Springs, Colo.

ANSWER.—Machado's communication (*Gazeta Medica da Bahia*, **50**:97 [September] 1918) refers to three patients treated with intravenous injections of sodium iodid. The first received twenty injections with a total of 142 gm. of sodium iodid, which corresponds to a concentration of 8.65 per cent., if it is considered that the first injection was of 20 c.c. and every succeeding one was increased 10 c.c. until reaching 100 c.c. per injection. The patient received a total volume of 440 c.c. in the first eight injections, followed by twelve injections of 100 c.c. each, forming a total of 1,640 c.c. with 142 gm. of iodid. This gives a concentration of $\frac{14,200}{1,640} =$ 8.65 per cent. In the second and third cases, by a similar computation, 10.92 per cent. and 9.75 per cent., respectively, represent the strength of solutions, giving an average for the three series of 9.77 per cent., or about 10 per cent.

VERACOLATE

To the Editor:—Please advise me as to the opinion of the Council on Pharmacy and Chemistry with regard to the "Veracolate" tablets.

D. W. A.

ANSWER.—The Council on Pharmacy and Chemistry examined Veracolate (the Marcy Company) in 1915 (THE JOURNAL, April 24, 1915, p. 1440), and found it to be semisecret in composition, unscientific in combination, and exploited under unwarranted claims. The following nonquantitative formula was given by the Marcy Company: "a compound containing bile acids, sodium glycocholate, sodium taurocholate with cascara sagrada and phenolphthalein."

Alabama January Examination

Dr. S. W. Welch, chairman, Alabama State Board of Medical Examiners, reports the written examination held at Montgomery, Jan. 11-14, 1919. The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 11 candidates examined, 4 passed and 7 failed. Three candidates were licensed through reciprocity, and one on his retirement from the United States Public Health Service. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
University of Alabama		(1918)	75
Emory University		(1918)	80.7
Meharry Medical College		(1918)	75.2
Vanderbilt University		(1918)	84.5
	FAILED		
Birmingham Medical College		(1914)	68.1
Atlanta College of Phys. and Surgs.		(1913)	62.1
Chicago College of Medicine and Surgery		(1918)	65
Meharry Medical College		(1917) 67.4; (1918)	70.6
Memphis Hospital Medical College		(1911) 65.1; (1913)	62.2

College	LICENSED BY ENDORSEMENT OF CREDENTIALS	Year Grad.	Certificate from
Meharry Medical College		(1914)	Missouri
Memphis Hospital Medical College		(1913)	Tennessee
University of Nashville		(1907)	Tennessee
University of Virginia		(1913)	U.S.P.H.S.

Missouri January Examination

Dr. George H. Jones, secretary of the Missouri State Board of Health, reports the written examination held at St. Louis, Jan. 28-30, 1919. The examination covered 14 subjects and included 100 questions. An average of 75 per cent. was required to pass. Twenty-one candidates were examined, all of whom passed. Eight candidates were licensed through reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
University of Kansas		(1918)	85.3
Johns Hopkins University		(1907)	86.1
Missouri Medical College		(1897)	80.3
St. Louis Coll. of Physicians and Surgeons		(1918)	75.1, 75.1, 75.1.
St. Louis University		(1918) 85.5, 89.9; (1919)	88.1
Washington University		(1905) 84.1; (1919)	86.1, 86.1, 86.3, 86.9, 87.1, 87.1, 87.2, 88, 90.4.
Temple University		(1918)	86.9
Meharry Medical College		(1917)	75.4

College	LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with

Book Notices

Infecciones de Tipo Gripal. Por los Doctores Antonio Piga, Médico de la Real Familia, y Luis Lamas, Profesor del Instituto de Alfonso XIII, con Notas de Terapéutica Clínica y Epidemiología de los Doctores Albasanz, Carro, Fernández Sanz, Grinda, Jiménez Asúa, Jiménez Encinas, Juarros, López Durán (B.) Marañón, Márquez, Mut, Oliver, Palancar, Perera, Sievert, Tolosa Latour y Verdes Montenegro. Tomo 1. Paper. Pp. 309. Madrid: Talleres Tipográficos de "Los Progresos de la Clínica," 1919.

The authors state in the preface that this book was not written hastily to take advantage of the interest in influenza aroused by the present epidemic, but that it is a study planned a long time ago for which the necessary material has been collected during the intervening period. "It is written," they say, "in the interest of science, with respect for truth, and with the desire of cooperating, however humbly, in the progress of Spanish medicine." The volume consists of eight chapters which discuss extensively the historical, clinical, and social aspects not only of epidemic influenza but of all influenzal infections. The influence of atmospheric changes on the appearance of such infections is emphasized, and stress is placed on the point that infection will most probably follow a rainy season. The necropsies and laboratory investigations made by the authors have enabled them to form an individual opinion as to treatment. Their chapter on this subject is divided into four sections, the first two concerning the history of anti-influenzal therapeutics, and the remainder "naturotherapy" or "leucogenous" treatment, which they consider the proper treatment of influenza. They state, however, that this treatment is unnecessary when the disease appears in mild form. In the class of leucogenous remedies they place the nucleinate of sodium, the metallic ferments, the essence of turpentine, and antidiphtheric serum. The book constitutes a minute review of the literature on influenzal diseases.

Accidents and Emergencies: A Manual of the Treatment of Surgical and Medical Emergencies in the Absence of a Physician. By Charles W. Dulles, M.D., Consulting Surgeon to the Rush Hospital. Eighth edition. Cloth. Price, $1 net. Pp. 164, with 45 illustrations. Philadelphia: P. Blakiston's Son & Co., 1918.

The repeated reprinting of this book indicates in a degree its usefulness to the laity, for whom it is intended. Undoubtedly information readily accessible in the emergencies of daily and family life serves a frequently recurring need. If a book containing such information does not overstep the boundary between the things a lay person may do and those which a surgeon or physician is alone competent to carry out, then it is of value in the home, the school, the playground or on the summer outing, and perhaps for the shop or factory where trained professional help is not provided. On this basis this book may be recommended for the purpose for which it was designed.

Introduction to Organic Chemistry. By John Tappan Stoddard, Professor of Chemistry in Smith College. Second edition. Cloth. Price, $1.50 net. Pp. 423. Philadelphia: P. Blakiston's Son & Co., 1918.

As the title indicates, this is an introduction to organic chemistry. Each phase of the subject is treated briefly and to the point. The book is to be recommended as presenting the elementary general principles of organic chemistry in an acceptable manner. From the standpoint of medical instruction, however, it does not connect these general principles closely enough with medicinal products. Some important subjects are too briefly considered; for instance, alkaloids and proteins are dismissed with but three pages each.

The Principles and Practice of Obstetrics. By Joseph B. DeLee, A.M., M.D., Professor of Obstetrics at the Northwestern University Medical School. Third edition. Cloth. Price, $8.50 net. Pp. 1089, with 949 illustrations. Philadelphia: W. B. Saunders Company, 1918.

As the author points out, the sum of obstetric knowledge has not been greatly advanced, since the publication of the second edition, but there have been several valuable additions. More important, however, time has been allowed for ascertaining the true valuation of several obstetric problems and methods that had not been thoroughly tried out up to that time. He mentions specifically the pregnancy reaction of Abderhalden, the relation of the endocrine glands to gestation, twilight sleep, and the urinary tests for the toxemias of gestation. Amplifications have been made in such obstetric problems and methods as anesthesia, analgesia, cesarean section and the treatment of contracted pelvis. In the treatment of eclampsia, more prominence is given to conservative methods, and as a result of the advance in the use of the rectal method of examination during labor, the section on the conduct of labor has been revised with this point in view. This textbook continues to be one of the most complete and best illustrated one volume work on practical obstetrics in English.

Social Medicine, Medical Economics and Miscellany

SOCIAL INSURANCE

The March number of the American Labor Legislation Review, published by the American Association for Labor Legislation, contains two articles on social insurance presented at the twelfth annual meeting of the association held at Richmond, Va., Dec. 27-28, 1918.

NEXT STEPS IN THE UNITED STATES

The president of the association, Prof. Samuel McCune Lindsay, in his presidential address discussed "Next Steps in Social Insurance in the United States." After reviewing the aims of the association and its activities during the past twelve years, he states that "social insurance is fundamental and vital to the aims and even to the very existence of the association, and that it lies at the heart of the most promising solution of the great task of social and industrial reorganization and reconstruction which the war has forced upon us." He then discusses the developing interest in social insurance in this country and the influence of governmental activities through the War Risk Insurance Bureau, and concludes that the next steps in social insurance in the United States are:

1. Provision for the most liberal conversion of war risk insurance for soldiers and sailors on terms equitable to the public.
2. Extension of similar insurance protection to all civilian employees of the government.
3. Development of health insurance for all governmental employees, and its extension as rapidly as possible to all citizens.
4. Establishment of state administered health insurance and insurance against accident, invalidity and old age as well as death for all industrial workers.

HEALTH AND OLD AGE INSURANCE IN OHIO

In the same number of the Labor Legislation Review, there is an article on "Health and Old Age Insurance in Ohio," by Mr. John A. Lapp, director of investigations of the Ohio Health and Old Age Insurance Commission. There are in that state approximately 5,250,000 people, 2,250,000 of whom are engaged in gainful occupations; 1,476,000 are under 14; 168,000 are over 70; 18,000 are inmates of state institutions; 4,850 are in state prisons and corrective institutions; 8,000 are in county infirmaries; 6,000 are in children's homes; 3,000 are in homes for the aged; 300,000 are supported either a part or all of the time by some form of public or charitable relief. Of the entire population of the state, 150,000 are disabled by sickness all the time. The investigations of the Ohio commission show that working people suffered an average sickness disability of nine days a year; that the burden that the worker is compelled to bear involves three factors, loss of wages, cost of medical care and loss of working power, and that the primary object of health insurance should be the restoration of the physical man to working efficiency. To accomplish this it is necessary to keep the incapacitated workman and his family from dependency until he is restored to efficiency. The objections to health insurance are thus summarized: 1. The cost is prohibitive. 2. The proposed plan fails to protect the unemployed and the casually employed. 3. The aim of legislation should be the prevention of sickness and not compensation for losses. 4. Industry and society are not liable for sickness. 5. Compulsory state health insurance is paternalistic and interferes with personal liberty. 6. Living wages will enable the worker to take care of himself.

Replying to the first, Lapp shows that health insurance, applied to 1,000,000 industrial workers in Ohio, will cost about $30,000,000 annually, and that existing sickness already costs the people more than twice that amount, a burden at present resting on the industrial worker and his family. The answer to the second objection is that social insurance does not apply to the unemployed or the pauper; that its function is to prevent people from becoming dependent, but that when they do it is the function of other agencies than social insurance to care for them. The unemployed have no wages to insure. If a man is not employed, he loses no wages when he is sick. Insurance cannot apply where there is no loss. To the objection that prevention rather than insurance should be undertaken, Lapp replies that they are not antagonistic but complementary and that neither can take the place of the other. To the objection that industry and society are not liable for sickness, he points out that all investigations have agreed that sickness results from three factors, the individual, the occupation and society at large, and that the burden must be distributed in proportion with the responsibility. The fifth objection, that of paternalism, Lapp says has been brought against every good measure that has been proposed in this country in the last fifty years. The sixth argument, that payment of a living wage will make state health insurance unnecessary by making it possible for each individual to carry his own burdens, Mr. Lapp denies, on the ground that it fails to take account of the risks of living which cannot be borne by the individual. "It is only by combining with others through forms of insurance that the gamble of life is eliminated. The most thrifty cannot make their life secure, because no one can tell what calamities of sickness and old age invalidity will be met. Thrift without insurance is often a delusion. There is no other way of assuring a living wage, covering present comforts and care in sickness and old age, except by insurance, and there is no way of providing adequate insurance at a reasonable cost except by making it universal through the state."

REPORT OF PENNSYLVANIA COMMISSION

The Pennsylvania Health Insurance Commission has made a tentative report in the form of a bill continuing the commission and authorizing a more extended study of the advantages and disadvantages of the proposed health insurance plan in Pennsylvania. The bill creates a health insurance commission authorized to continue the investigation begun by the existing commission; to make a study of proposed and existing systems of health insurance for this and other countries; to study possible remedial legislation intended to provide adequate medical care for employees and their families during sickness, to meet the wage loss suffered by employees during sickness, and to stimulate state wide interest and active work in sickness prevention. The commission is authorized to hold public meetings in different parts of the state, and is instructed to present to the general assembly of 1921 a full and final report containing such recommendations for legislation or otherwise as it may deem proper. The commission is to consist of three senators and three representatives of the house of representatives appointed by the speakers of the two houses, respectively, and five other persons not members of the general assembly to be appointed by the governor. The usual powers of organization and investigation, administering oaths, etc., are provided. The commissioner of health and the commissioners of labor and industry of the state are directed to cooperate. Twenty-five thousand dollars is appropriated for the expenses of the commission.

Conditions Warranting Requirement of Vaccination

(Hagler et al. v. Larner et al. (Ill.), 120 N. E. R. 575)

The Supreme Court of Illinois affirms a decree that dismissed as without equity a bill of complaint whereby it was sought to enjoin the defendants from preventing the complainants from attending the public schools of Granite City unless they were first vaccinated, according to a resolution adopted by the local board of health that all children should be excluded from the public schools for a period of two weeks unless recently vaccinated, or unless they produced a certificate that they had been successfully vaccinated within the past five years or had had smallpox. The court says that the exact question raised in this case seems never to have been passed on directly by this court, as it appeared from the stipulations that smallpox was epidemic and prevalent in Granite City, and that there actually existed a large number of cases of smallpox when the resolution was passed and enforced, and that the board, acting under the authority conferred by a city ordinance, passed the resolution for the purpose of preventing the spread of the disease and of preserving the health of the citizens. The rule is firmly established in Illinois that school directors and boards of education have no authority to exclude children from the public school on the ground, simply, that they refuse to be vaccinated, unless in cases of emergency, in the exercise of the police power, it is necessary or reasonably appears to be necessary to prevent the contagion of smallpox. But it appeared in the cases wherein that rule was established that there was no epidemic or prevalence of smallpox and that the pupils were in a healthy condition and had not been exposed to smallpox, and this court held it to be unreasonable to require vaccination as a prerequisite to admission to the public schools in such cases, and that there was no law of the state of Illinois authorizing such action.

The resolution of the board of health in this case was reasonable in view of the fact that smallpox was epidemic and the disease likely to spread from the many cases then existing in the city. The state statute empowered the city council "to appoint a board of health and prescribe its powers and duties," and also "to do all acts, make all regulations which may be necessary or expedient for the promotion of health or the suppression of disease." The city ordinance referred to conferred on the board of health power to make such rules and regulations and such sanitary investigations as the board might from time to time deem necessary for the preserving and improvement of the public health on the appearance in epidemic form of smallpox, etc. These provisions of the state and the ordinance conferred on the board of health ample authority to pass the resolution it did, under the existing facts.

As it was the duty of the board of health to enforce such reasonable rules and regulations as would stamp out the epidemic and promote the public health, and the resolution seemed well calculated to accomplish that purpose and as a public necessity existed for such action, the board must be held to have acted legally in passing the resolution, and the school board in enforcing it and requiring vaccination as a condition to pupils entering the schools. The exercise of such authority by the board of health and the school board finds ample authority in the police power of the state when such a necessity arises as was shown in this case, and no constitutional rights of the complainants were violated. No child has a constitutional right to carry to others in school the loathsome disease of smallpox.

While it is true that occasionally very disastrous results happen from the use of impure vaccine, and there are many people, for that or other reasons, who resist, and have the right to resist, compulsory vaccination of their children except in cases of necessity; yet they have no right to insist on their children continuing in school and mixing in large congregations without obeying such requirements when smallpox is epidemic in the community and such children perhaps have

Book Notices

INFECCIONES DE TIPO GRIPAL. Por los Doctores Antonio Piga, *Médico de la Real Familia*, y Luis Lamas, Profesor del Instituto de Alfonso XIII, con Notas de Terapéutica Clínica y Epidemiología de los Doctores Albasanz, Carro, Fernández Sanz, Grinda, Jiménez Asúa, Jiménez Encinas, Juarros, López Durán (B.) Marañón, Márquez, Mut, Oliver, Palancar, Perera, Sievert, Tolosa Latour y Verdes Montenegro. Tomo 1. Paper. Pp. 309. Madrid: Talleres Tipográficos de "Los Progresos de la Clínica," 1919.

The authors state in the preface that this book was not written hastily to take advantage of the interest in influenza aroused by the present epidemic, but that it is a study planned a long time ago for which the necessary material has been collected during the intervening period. "It is written," they say, "in the interest of science, with respect for truth, and with the desire of cooperating, however humbly, in the progress of Spanish medicine." The volume consists of eight chapters which discuss extensively the historical, clinical, and social aspects not only of epidemic influenza but of all influenzal infections. The influence of atmospheric changes on the appearance of such infections is emphasized, and stress is placed on the point that infection will most probably follow a rainy season. The necropsies and laboratory investigations made by the authors have enabled them to form an individual opinion as to treatment. Their chapter on this subject is divided into four sections, the first two concerning the history of anti-influenzal therapeutics, and the remainder "naturotherapy" or "leucogenous" treatment, which they consider the proper treatment of influenza. They state, however, that this treatment is unnecessary when the disease appears in mild form. In the class of leucogenous remedies they place the nucleinate of sodium, the metallic ferments, the essence of turpentine, and antidiphtheric serum. The book constitutes a minute review of the literature on influenzal diseases.

ACCIDENTS AND EMERGENCIES: A MANUAL OF THE TREATMENT OF SURGICAL AND MEDICAL EMERGENCIES IN THE ABSENCE OF A PHYSICIAN. By Charles W. Dulles, M.D., Consulting Surgeon to the Rush Hospital. Eighth edition. Cloth. Price, $1 net. Pp. 164, with 45 illustrations. Philadelphia: P. Blakiston's Son & Co., 1918.

The repeated reprinting of this book indicates in a degree its usefulness to the laity, for whom it is intended. Undoubtedly information readily accessible in the emergencies of daily and family life serves a frequently recurring need. If a book containing such information does not overstep the boundary between the things a lay person may do and those which a surgeon or physician is alone competent to carry out, then it is of value in the home, the school, the playground or on the summer outing, and perhaps [illegible] factory where trained [illegible] this

basis this by the defendant that "the liability imposed contained in the policy of indemnity, referred to mon-law liability only, and it was argued that a surgeon, under the law, is not required to enter into a contract, but is liable only for failure to exercise diligence, care, and skill such as is ordinarily possessed by the members of his profession in good standing, and that when he made a contract to do more than that he took on himself a liability not imposed by law. This reasoning would no doubt be sound in case of malpractice on the part of a physician, but clearly the physician had a right to enter into a contract to remove all gallstones from the body of his patient and to effect a cure. He clearly had a right to do this in the practice of his profession; and if he made an error or mistake, or was guilty of malpractice, and damages resulted thereby to his patient, a recovery might be had. The words "malpractice," "error," and "mistake," as used in this indemnity policy, did not mean necessarily the same thing. The words "liability imposed by law" clearly referred to a judgment recovered on account of malpractice, error, or mistake, and did not limit the policy to cases in which there was simply malpractice, in which the physician was required to use care, diligence, and such skill as is ordinarily possessed by the average members of the profession in good standing. The judgment in the Schuster

More important, however, time has been allowed for ascertaining the true valuation of several obstetric problems and methods that had not been thoroughly tried out up to that time. He mentions specifically the pregnancy reaction of Abderhalden, the relation of the endocrine glands to gestation, twilight sleep, and the urinary tests for the toxemias of gestation. Amplifications have been made in such obstetric problems and methods as anesthesia, analgesia, cesarean section and the treatment of contracted pelvis. In the treatment of eclampsia, more prominence is given to conservative methods, and as a result of the advance in the use of the rectal method of examination during labor, the section on the conduct of labor has been revised with this point in view. This textbook continues to be one of the most complete and best illustrated one volume work on practical obstetrics in English.

Social Medicine, Medical Economics and Miscellany

SOCIAL INSURANCE

The March number of the American Labor Legislation Review, published by the American Association for Labor Legislation, contains two articles on social insurance presented at the twelfth annual meeting of the association held at Richmond, Va., Dec. 27-28, 1918.

NEXT STEPS IN THE UNITED STATES

The president of the association, Prof. Samuel McCune Lindsay, in his presidential address discussed "Next Steps in Social Insurance in the United States." After reviewing the aims of the association and its activities during the past twelve years, he states that "social insurance is fundamental and vital to the aims and even to the very existence of the association, and that it lies at the heart of the most promising solution of the great task of social and industrial reorganization and reconstruction which the war has forced upon us." He then discusses the developing interest in social insurance in this country and the influence of governmental activities through the War Risk Insurance Bureau, and concludes that the next steps in social insurance in the United States are:

1. Provision for the most liberal conversion of war risk insurance for soldiers and sailors on terms equitable to the public.
2. Extension of similar insurance protection to all civilian employees of the government.
3. Development of health insurance for [illegible] employees, and its extension [illegible] citizens

TENNESSEE STATE MEDICAL ASSOCIATION

Eighty-Sixth Annual Meeting, held at Nashville, April 8-10, 1919

The President, DR. RICHMOND MCKINNEY, Memphis, in the Chair

The Puzzle of the Gastric Ulcer

DR. W. N. LYNN, Knoxville: The so-called classical symptoms of gastric ulcer—pain, hemorrhage and vomiting—may be presented in appendicitis or in a case of simple intestinal kink. Suppose at operation a simple ulcer is excised, and the pathologist finds groups of cells resembling carcinoma, surrounded by connective tissue, at the margin of the ulcer. If this ulcer history goes back four or six or eight or nine years, what evidence have we that the ulcer was not malignant from the first? Until we know more concerning the life history of gastric cancer, are we in position to deny that gastric cancer may exist for years? We know but little about the clinical history of carcinoma, and when we say a patient has an ulcer history of six or seven years, how can plish this it is necessary to keep the incapacitated workman and his family from dependency until he is restored to efficiency. The objections to health insurance are thus summarized: 1. The cost is prohibitive. 2. The proposed plan fails to protect the unemployed and the casually employed. 3. The aim of legislation should be the prevention of sickness and not compensation for losses. 4. Industry and society are not liable for sickness. 5. Compulsory state health insurance is paternalistic and interferes with personal liberty. 6. Living wages will enable the worker to take care of himself.

Replying to the first, Lapp shows that health insurance, applied to 1,000,000 industrial workers in Ohio, will cost about $30,000,000 annually, and that existing sickness already costs the people more than twice that amount, a burden at present resting on the industrial worker and his family. The answer to the second objection is that social insurance does not apply to the unemployed or the pauper; that its function is to prevent people from becoming dependent, but that when they do it is the function of other agencies than social insurance to care for them. The unemployed have no wages to insure. If a man is not employed, he loses no wages when he is sick. Insurance cannot apply where there is no loss. To the objection that prevention rather than insurance should be undertaken, Lapp replies that they are not antagonistic but complementary and that neither can take the place of the other. To the objection that industry and society are not liable for sickness, he points out that all investigations have agreed that sickness results from three factors, the individual, the occupation and society at large, and that the burden must be distributed in proportion with the responsibility. The fifth objection, that of paternalism, Lapp says has been brought against every good measure that has been proposed in this country in the last fifty years. The sixth argument, that payment of a living wage will make state health insurance unnecessary by making it possible for each individual to carry his own burdens, Mr. Lapp denies, on the ground that it fails to take account of the risks of living which cannot be borne by the individual. "It is only by combining with others through forms of insurance that the gamble of life is eliminated. The most thrifty cannot make their life secure, because no one can tell what calamities of sickness and old age invalidity will be met. Thrift without insurance is often a delusion. There is no other way of assuring a living wage, covering present comforts and care in sickness and old age, except by insurance, and there is no way of providing adequate insurance at a reasonable cost except by making it universal through the state."

REPORT OF PENNSYLVANIA COMMISSION

lost no [illegible] Health Insurance Commission has made that his vision was [illegible] bill continuing the com- and several retinal hemorrhages were discovered [illegible] recognized the case as possibly one of nephritis, and referred the patient to me for a thorough examination. I found the highest diastolic pressure I have yet come across in any case; it was 170, and the systolic pressure was 240. Urinalysis detected no albumin. The phenolsulphonephthalein test yielded 13 per cent. in the first two hours. A specimen of urine was collected and found to contain a trace of albumin, with a few hyaline and granular casts. In all probability, this man is totally incapacitated. I believe that if this man had undergone periodic examinations, with blood pressure readings five years ago, a great deal of his present condition might have been averted.

DR. FRANK A. JONES, Memphis: In some cases, on account of the high systolic, diastolic and pulse pressure, we give a grave prognosis. In other instances, when the general condition seems very good, when the blood pressure is not so high, and the heart not much dilated, with no casts nor albumin in the urine, we render a favorable prognosis, and the patient suddenly drops dead, whereas the other patient, presenting grave conditions, lives for years. Textbooks have not paid sufficient attention to angina abdominalis. I believe we have as many cases of angina abdominalis as we have of angina pectoris. We find a number of cases of angina renalis and angina hepatalis. We likewise find, perhaps, a

Conditions Warranting Requirement of Vaccination

(*Hagler et al. v. Larner et al. (Ill.), 120 N. E. R. 575*)

The Supreme Court of Illinois affirms a decree that dismissed as without equity a bill of complaint whereby it was sought to enjoin the defendants from preventing the complainants from attending the public schools of Granite City unless they were first vaccinated, according to a resolution adopted by the local board of health that all children should be excluded from the public schools for a period of two weeks unless recently vaccinated, or unless they produced a certificate that they had been successfully vaccinated within the past five years or had had smallpox. The court says that the exact question raised in this case seems never to have been passed on directly by this court, as it appeared from the stipulations that smallpox was epidemic and prevalent in Granite City, and that there actually existed a large number of cases of smallpox when the resolution was passed and enforced, and that the board, acting under the authority conferred by a city ordinance, passed the resolution for the purpose of preventing the spread of the disease and of preserving the health of the citizens. The rule is firmly established in Illinois that school directors and boards of education have no authority to exclude children from the public school on the ground, simply, that they refuse to be vaccinated, unless in cases of emergency, in the exercise of the police power, it is necessary or reasonably appears to be necessary to prevent the contagion of smallpox. But it appeared in the cases wherein that rule was established that there was no epidemic or prevalence of smallpox and that the pupils were in a healthy condition and had not been exposed to smallpox, and this court held it to be unreasonable to require vaccination as a prerequisite to admission to the public schools in such cases, and that there was no law of the state of Illinois authorizing such action.

The resolution of the board of health in this case was reasonable in view of the fact that smallpox was epidemic and the disease likely to spread from the many cases then existing in the city. The state statute empowered the city council "to appoint a board of health and prescribe its powers and duties," and also "to do all acts, make all regulations which may be necessary or expedient for the promotion of health or the suppression of disease." The city ordinance referred to conferred on the board of health power to make such rules and regulations and such sanitary investigations as the board might from time to time deem necessary for the preserving and improvement of the public health on the a[illegible] form of smallpox, etc. These pro- [illegible]iac. Paranoiacs ought [illegible] conferred on the board selves and so treated. I do not believe [illegible] it did, under of patients vocationally unless it is special tra[illegible] for safety.

DR. S. S. CROCKETT, Nashville: There are many mo[illegible] paranoiacs abroad than are found in institutions. Some are found in the medical profession, the legal profession, and in business pursuing vocations of great responsibility; but such men are known among their friends as cranks. They never settle disputes by arbitration. They fight them out. They think somebody is trying to "do" them. The paranoiac has two notable characteristics, egotism and suspicion. The egotism of the paranoiac leads him to undertake to reform the world. Paranoiacs may have delusions of persecution, of homicide or suicide; but when you put them on the witness stand before a jury they make fine witnesses, and no jury will send them to an institution unless they have committed violence.

Fracture of Pelvis: Report of Four Cases

DR. E. T. NEWELL, Chattanooga: Case 1 was a fracture of the tibia with fracture of the horizontal ramus of the pubis and ascending ramus of the ischium, complicated by injury to the external iliac artery of the same side, foll[illegible]

[illegible]ne and amputation of the leg. Case 2 [illegible]

[illegible]orizontal ramus, os pubis, and [illegible] the ischium of the right side, with rupture of the bladder, peritonitis and obstruction of the bowel. Case 3 was a fracture of the descending ramus of the os pubis, with rupture of the membranous urethra, followed by stricture. Case 4 was a simple, uncomplicated fracture of the horizontal ramus, os pubis and ascending ramus of the ischium. There were no complications. All four patients recovered. All have good functional results with the exception of the man who had to have the leg amputated, and he has no pain nor discomfort at the site of the pelvic fracture. There was no special treatment of these pelvic fractures aside from the immobilization of the patient on the back on the Allen stretcher. I believe that the less we manipulate the bone, and the more quiet we keep the patient, the fewer complications we have and the better will be our result.

Achylia Gastrica

Dr. Otis S. Warr, Memphis: Achylia gastrica is merely a symptom. Cases occurring in individuals past middle life should be regarded with suspicion and repeated search be made for some organic cause lest a beginning malignancy be overlooked. No case should be regarded as a true achylia gastrica based on the result of an Ewald test meal. If this test reveals an achylia, a fractional analysis should be done and carried over a period of at least two hours. If, in the course of a routine examination, achylia is discovered in an individual who is suffering no particular digestive disturbance, one should be careful not to attach too much importance to this finding, lest the patient imagine he has some serious disease and thus become a confirmed neurasthenic. In the management of achylia, one should have no routine plan but should individualize in every case.

DISCUSSION

Dr. William Krauss, Memphis: It is high time that the general practitioner begin to recognize the value of fractional analyses of stomach contents. I am sure that every one who has adopted this method will consider that the information he has obtained from the use of the old large tube with single aspiration is valueless in determining the possibilities of acid secretion. By the fractional methods we are able to determine not only the highest point of acidity but also the period at which the highest point of acidity occurs, which is of considerable value.

Dr. Frank A. Jones, Memphis: I have seen a number of cases of achylia gastrica that did not develop cancer of the stomach. Achylia gastrica is more frequent in myasthenic, psychasthenic, high-strung, nervous women than in any other class of patients. Achylia gastrica bears about the same relation to these psychasthenic conditions as do the hysterical paralyses, hysterical paraplegias and hysterical phobias. The sovereign remedy in cases of achylia gastrica is hot water before meals, in large drafts; hot baths, morning and night, soaking the patients in the hot water bath for half an hour; and the drinking of a gallon of hot water every day. Heat tones blood pressure. I have seen the blood pressure not more than 80 in these cases; in one case it was 72.

Dr. Jack Witherspoon, Nashville: One interesting point about achylia gastrica is the fact that these patients have no pylorospasm. They have no contractions at the external end of the stomach, and foodstuff passes through very rapidly. This probably accounts for the large number of cases of intestinal fermentation and resultant intestinal diarrheas we see in this disease.

Some Practical Procedures Used by the Army That Are Applicable to Civil Work

Dr. Lucius E. Burch, Nashville: Shock is a condition frequently found both in civil and in military practice. Many of the soldiers brought in from the battlefield were in profound shock. A special shock ward was set aside in the evacuation hospitals for the treatment of these cases. It is necessary to keep a shock patient warm, and restore the loss in body heat. This was done by a simple appliance. Wooden boxes, the length of a litter and about 2 feet high, were made without floor or roof. An opening was made in one end of the box sufficiently large to carry a pipe leading from an oil stove which was placed at one end. The litter containing the patient is placed on the box, the stove lighted, and the patient covered with blankets. The heat is conducted from the stove through the pipe to the space beneath the patient, and serves the desired purpose.

In no field of surgery have greater advances been made than in fractures. The American surgeon has been so accustomed to use plaster of Paris that he was slow in adopting the metal splints of the English. Many of these splints are old friends that had been relegated to the junk pile and were brought out during the war. The old Thomas hip splint is an admirable apparatus. It continually maintains traction; abduction is easily carried out, and transportation is made comfortable. It may also be used advantageously in fractures of the leg. In this class of fractures it is rarely necessary to do an open operation, if this splint is used in connection with the Sinclair skid. It also has the advantage that patients may be moved to the roentgen-ray room for observation. An additional advantage is that when the bone is sufficiently united, it may be used as an ambulatory splint.

An operation that impressed me more than any other was for arteriovenous aneurysm. It is a method brought out by Major Connors, chief of the surgical service, Base Hospital No. 8, Saveney, France. The technic is quite simple. The vein is ligated both on the distal and the proximal side of the aneurysm. That part of the vein which is affected by the aneurysm is then bisected between the two ligatures and stitched over the opening in the artery by interrupted sutures.

DISCUSSION

Dr. Battle Malone, Memphis: With reference to shock, it was astonishing to me to see with what rapidity our wounded soldiers in Europe reacted from shock by carrying out the method mentioned by Dr. Burch. As to the treatment of joint injuries, septic joints were laid wide open, and motion was begun early, except in cases of fracture or a complicating embolism; then motion could not be kept up. In joint injuries the wounds were closed unless it was known that the joints were infected at the time the wounded soldiers came in.

Blastomycosis

Dr. J. M. King, Nashville: The treatment I use in these cases consists of thorough curetting, the application of very hot sponges, followed with local application of pure phenol, followed by alcohol, wet mercuric chlorid dressings under oiled silk, roentgen ray and iodids, with complete recovery.

Intestinal Obstruction

Dr. Robert Caldwell, Nashville: If we are to lower the mortality of intestinal obstruction, early diagnosis and prompt surgical relief are absolutely essential. Operative measures used in the relief of this condition are mainly two, first, relief of the obstruction and second, empting of the toxic material that has been produced. An enterostomy should be done only in cases in which obstruction cannot be dealt with, or when there is a loop of obstruction; then an enterostomy should be done above the proximal point of obstruction.

Early Spanish-American Medicine.—In the University of Guatemala, there are still in use for medical teaching three rather curious wax models made in the eighteenth century by Dr. José Flores, a former professor of medicine in that college. One of them is used to explain osteology and represents the human skeleton, showing the bones on one side and on the other the nerves and veins. The second model is for the classes in myology and represents a man with the muscles falling loose from the bones. The third figure is employed for lessons in neurology, and is a human figure whose head and abdomen can be opened to show the inside structure. Flores was the author of a pamphlet published in Mexico in 1782 on "a specific recently discovered in Guatemala for the radical treatment of chancres." A note on the title page of the book states that the treatment consisted in eating some lizards that grow in Guatemala.—From Beristain's Biblioteca Hispano Americana.

Status of Uterine Curettage.—The statistics given by Rawls are not favorable to the performance of this procedure either as a diagnostic or a therapeutic measure.

Induction of Labor by Use of Bougies.—Foulkrod uses two silk bougies, with or without iodoform gauze packing, to induce labor. These bougies must be well placed, that is, the patient must be in a good position on the edge of the table or bed and must be very well self controlled or must be controlled with anesthesia so that the operator can introduce two fingers into the cervix anterior to the child's head and can see that the bougies go directly up to the cavity without bending. When two bougies are so placed, gauze is packed into the cervix and into the vagina. The patient is returned to bed and the onset of labor pains awaited. Foulkrod prefers to wait even two days before changing the bougies.

Extrameningeal Meningococcus Infections.—Three hundred and fifteen cases of meningococcus infection were studied by Herrick at Camp Jackson. In approximately 40 per cent. the diagnosis was made before meningitis devoloped. In 5 per cent. meningitis never developed at all. With few exceptions the earliest evidences of meningitis were preceded by symptoms of a general infection lasting from a few hours to several days, in exceptional instances, weeks. This initial stage of sepsis was repeatedly proved by blood culture, by clinical studies and necropsies. Herrick regards epidemic cerebrospinal meningitis as being a blood stream invasion, a sepsis, at first, for a period averaging forty-eight hours, often more, at time less. Later there is the local process, usually in the meninges, not infrequently elsewhere. To emphasize the extrameningeal rôle of the meningococcus, Herrick reports six cases in which meningitis was absent or a subordinate part of the disease process. These cases were: (1) Meningococcus sepsis without meningitis either clinically or at necropsy. (2) Meningococcus sepsis without clinical meningitis: at necropsy, meningeal congestion and arachnoid cell hyperplasia—the earliest stages of meningitis. (3) Meningococcus sepsis without meningitis; septic polyarthritis; recovery with intravenous treatment. (4) Meningitis tarda, or meningitis with premeningitic stage of meningococcemia of several weeks' duration. (5) Meningococcus pleurisy. (6) Meningococcus empyema of accessory nasal sinuses, both without meningitis. Herrick recommends that the term epidemic cerebrospinal meningitis should be abandoned, and that the term meningococcus infection should be used to denote such general processes as meningococcus sepsis. Meningococcus meningitis should be the term used in the case of meningococcus infection with predominant cerebrospinal symptoms.

Effects of Louse Bites.—Previously reported observations by Moore indicated that a macular erythematous skin eruption, somewhat resembling that of measles or German measles, distributed over the chest, back and abdomen, may occur in a normal person who allows lice to feed on the skin of his forearm only. This eruption was accompanied by general lassitude and malaise, headaches, and peculiar pains in the calves of the legs and soles of the feet, particularly under the toes. The present series of observations made by Hirschfelder and Moore was undertaken to determine whether the previously recorded observations represented a peculiarity of the individual on whom the lice had fed, or whether it might be regarded as a general phenomenon. Four perfectly healthy young men volunteered for the experiments. They were normal, except in some cases for the enlargement of a lymph gland here and there. Each of the subjects allowed himself to be bitten twice daily by the number of lice specified. These lice were raised from eggs and had never fed on any except healthy individuals. In every individual bitten, except one, there was a prompt rise of temperature, ranging from 99.3 to 99 F., after the lice had been fed. Sometimes, this occurred with surprising rapidity and the temperature reached 99.9 F. within an hour after feeding. In three out of four of the subjects a well defined rash composed of semilunar and crescentic macules from 2 to 3 mm. in size resembling those of a fading measles or German measles occurred. The rash was not very striking and yet was definite enough to be seen without difficulty when it was at its height. The macules disappeared on pressure. It was distributed over the chest, back and upper abdomen, and in no case appeared on the face, neck, arms or lower limbs. It was always most distinct and persisted longest in the regions between the nipples and the lower costal margins.

The authors conclude that their observations point strongly toward the presence of a substance in the louse sufficiently

Late Results in Stomach Surgery.—In this paper Schwyzer emphasizes the fact that the surgical results in stomach cases are not short-lived. Leaving aside all the cases which were observed for less than a year after the operation, Schwyzer has, including carcinomas, recent reports from 91 patients. Of these are well, 62; geatly impoved, 12; improved, 15; temporarily improved, 2. Of those observed for two years or longer, reports were received from 72. Of these are well, 49; greatly improved, 12; improved, 11. Of 47 patients observed 5 years or over, 31 are well today; 9 greatly improved; 7 improved. Ten patients were observed for more than twelve years. Of these, 8 are well today; 1 greatly improved; 1 improved. Schwyzer had 15 acute perforations of ulcers with 4 deaths, 27 per cent. Carcinoma of the stomach, 26 cases with 1 death. Ulcers, including strictures of pylorus, 76 cases with 1 death. Acute perforations of ulcers, 15 cases with 4 deaths. Ptosis and dilatation without definite stricture, 13 cases with no deaths. Unclassified cases, mostly indistinct indications, 9 cases with 2 deaths. Total: 139 cases with 8 deaths. Grouped according to the operative procedures, he had among the other cases, including the carcinomas: Eighty-six gastroenterostomies, with 2 deaths, 2⅓ per cent. Thirteen pyloroplasties (Finney), with 1 death, 8 per cent. Thirteen gastroplications (partly with other op.), with no deaths, 0 per cent. Twenty resections, with 1 death, 5 per cent. This investigation would indicate that the patient who is completely relieved of his symptoms for a year after the operation most always stays cured.

Spinal Cord Surgery.—Of forty-five cases treated by Sachs, twenty-seven were cases of spinal tumors or those diagnosed as such, a much larger percentage than is ordinarily believed to occur. Sachs emphasizes that the earliest symptom of a focal lesion is usually paresthesia and not pain, in fact, pain is not a necessary symptom for the diagnosis of a spinal lesion. [illegible] Lead twenty-seven cases in which operation was performed for tumor, a tumor was found and removed in thirteen. In six there was a serous pachymeningitis or local collection of fluid, practically a cyst, while in six the findings were negative, but three of these six operations were performed on one patient. So that there was a mistake in diagnosis in four cases. There were two deaths in this group, a mortality of 9.5 per cent. Sachs feels very strongly that every patient with symptoms of a focal spinal lesion has not had a fair chance until they have been explored. He advocates laminectomy because when carefully carried out it is attended by little danger.

Military Surgery at Belgian Front. V. A. Robertson, Brooklyn.—p. 639.

Joint Hypotonia.—The case cited by Jahss is said to be the second on record. The child was 17 months old. The shoulder joints were normal; adduction and abduction of the elbows, with forearm extended on the arm, was possible with a range of motion of about 5 degrees either way. Flexion and extension appeared normal. The dorsum of the hand could be approximated to the dorsum of the forearm and the palm of the hand could be placed on the anterior surface of the forearm. Pronation and supination of the wrist proper was possible in an arc of about 120 degrees. In the fingers this unusual degree of flexion and extension was present. Examination of the lips showed a double congenital dislocation which was confirmed by the roentgen ray; flexion of the knees was normal. Hyperextension was very mild. Internal and external rotation were possible to an extent of 90 degrees; on dorsiflexion the entire foot, including the toes, could be placed on the crest of the tibia. In plantar flexion the planes of the foot and leg were in one straight line. Eversion and inversion were markedly increased. The same degree of mobility was present in the metatarsophalangeal joints. Rotation of the head on the neck showed that the point of the chin reached a point about 30 degrees posterior to the shoulder. All normal reflexes were present. There was neither a quantitative nor a qualitative reaction of degeneration when the faradic and galvanic currents were applied. No pathologic reflexes were elicitated. This case agrees in practically all particulars with the one reported by Finkelstein. It is both congenital and familial; the muscle power seemed normal; the reflexes were present; there was no reaction of degeneration; involvement of the bone was not found present, and practically every joint of the body was involved.

Half a Century of Smallpox and Vaccination. J. C. McVail.—p. 339.

Etiology of Influenza.—This is a preliminary report of the experimental work done by Gibson, Bowman and Connor with a filtrable organism. They succeeded in growing a minute micro-organism of a coccoid shape by Noguchi's cultural methods from: (*a*) the kidney of infected animals; (*b*) the filtrates of lung tissue, and (*c*) the filtered sputum from cases of influenza. The cultures have been carried to the third generation by direct culture. The cultures when inoculated into animals produced typical "experimental influenzal" lesions, and cultures were recovered again from the animals so inoculated. The pathologic lesions in what may be called experimental influenza in animals closely resemble those seen in the lungs of men. Some evidence was obtained in favor of the view that the passage of the virus from one animal to another may raise its virulence. Inoculation of the filtered and unfiltered sputum taken from cases of influenza, especially at an early stage of the disease, has been found to produce lesions in the lungs in a high proportion of inoculated animals.

Hyperthyroidism in Exhausted Soldiers. — Temporary exophthalmos was noted by Johnson in the early stage of advanced conditions of exhaustion. When it disappeared the patient at once merged into the group of cases labeled "neurasthenia," and was indistinguishable from them. Johnson suggests that a large number of so-called psychoneuroses are cases in which the symptoms are due to a state of disordered internal secretion, the result largely of emotional exhaustion, and, to a less degree, of physical exhaustion. Many cases, later diagnosed as irritable heart, D. A. H., soldier's heart, and neurasthenia, are really cases of this class, and possibly many have passed through a slight state of exophthalmos without its importance being realized. Johnson further suggests the advisability of classing the whole group under a suitable term. "Exhaustion syndrome."

Bacteriologic Findings in Influenza.—Over 150 influenza sputums were examined by Munro by film and by culture. In about half the number, short gram-negative bacilli were found on the slide. In some specimens these occurred in enormous numbers, but there was never wanting plenty of gram-positive diplococci and streptococci. Gram-negative diplococci were also seen, and none of these proved to be a meningococcus. They were probably *M. catarrhalis* or members of that group. Staphylococci were seen fairly commonly. It is suggested that the influenza bacillus was probably present in all cases at the begininng of the illness, and that the pneumococcus and the streptococcus were mainly responsible for the pulmonary complications.

Typhoid Carrier for Thirty-Seven Years.—Champtaloup cites the case of a man, aged 72, who had worked at sheep-shearing, bush-falling, and as a general farm servant in and about the same district in New Zealand for nearly forty years. He had never been engaged in cooking or otherwise handling food at the farms or stations at which he worked. He had had typhoid fever in 1881. He suffered a relapse, and was in the hospital thirty-seven weeks. On five different occasions (from 1888 until 1918) men working with him became ill with typhoid. On examination it was found that his serum agglutinated his own bacillus up to 1:300, and agglutinated the standard (Oxford) strain of *B. typhosus* up to 1:250. Very numerous typhoid colonies on MacConkey plates, and in almost pure culture, were found in his feces on several occasions.

Fitness and Unfitness in Convalescence. B. Parsons-Smith.—p. 509.

Influenza Pneumonia with Hemorrhagic Spinal Meningitis.—Osler cites a case of influenza pneumonia with bilateral rigidity, spinal meningitis with hemorrhage into the vecca vertebralis and nerve roots. The neck was so rigid that the patient could not lift the head from the pillow: The spine was arched, the muscles strongly contracted. Both upper limbs were in toxic spasm, the arms more than the forearms; he could extend and flex the fingers; he could not move the arms from the side; at intervals there was slight tremor. Both legs were rigid; the muscles stood out prominently, and the foot was extended; slight ankle clonus, knee-jerks not obtainable, nor the Babinski sign. On the skin of feet and ankles was a crop of fresh purpura. The breathing was largely abdominal, movements of the chest were very slight, but more on the right than on the left side. Dulness shaded to flatness from the fourth left rib upward, extending into the axilla and as high as the angle of the scapula behind; intense tubular breathing with fine crepitant râles was present. The heart sounds were clear. He had, in addition, well-marked purpura. Lumbar puncture was negative. Blood cultures were negative. Necropsy: Into the spinal theca and extending along the nerve-roots into the foramina was a uniform sheeting of hemorrhage obliterating the spinal veins, dense enough to cover completely the nerve-roots and involving their sheaths; it was more marked in the posterolateral than in the anterior portions. There was no free blood in the spinal canal; the hemorrhage was entirely into the theca.

Gonorrhea Treated by Pus Vaccine.—The gonorrheal pus vaccine first suggested by Lickley was used with good results by Pineo and Baillie. For chronic cases this vaccine was combined with emulsion of ten strains of gram-positive diphtheroid bacilli and of seven strains of *S. albus* isolated from chronic cases. The minimum doses of these bacteria were 60 million and 240 million, respectively. The type of cases most benefited by vaccines were: (*a*) chronic gleet, stage coming on about twenty to twenty-five days after commencement of discharge, with gonococci, intracellular and extracellular, in the discharge; (*b*) relapses generally stirred into activity by recent and repeated sexual connections, with drinking bouts; (*c*) cases of gonorrheal rheumatism in acute or chronic stage; (*d*) gonorrheal ophthalmia, either metastatic or local infection type; (*e*) the rare cases of gonorrheal septicemia. The scheme of dosage most satisfactory was 6 million, 12 million, 18 million, 24 million, 36 million, 60 million, 72 million, 90 million, 120 million and 150 million doses given at three days' intervals. If a rise of temperature occurred after any dose, that dose was repeated on the next occasion, and, in one or two cases, one dose lower in the scale. Most patients were cured by the time they reached the 60 to 72 million doses. The most obstinate were cases of relapse after a long interval from their previous treatment. The majority of those were admitted with chronic gleet, with a few fine shreds in their urine. They show, according to the authors' figures, a high resistance to any vaccine. They are unable to show control cases of other vaccines, but in their hands this vaccine has given incomparably better results than any previously used by them.

*Study of Epileptiform Convulsions in Soldiers. R. G. Gordon.—p. 159.
Hysterical Cases in Soldiers. G. McGregor.—p. 167.

Hysterical Element in Organic Disease and Injury of Central Nervous System.—Experience with soldiers has led Hurst and Symns to believe that the association of hysterical symptoms grafted on symptoms caused by organic disease is much more common than has generally been supposed. In fact, they claim that there are few symptoms caused by organic disease which are not liable to be aggravated and perpetuated by suggestion, so that it becomes necessary in almost every case of impaired function to look for a hysterical element which can be removed by psychotherapy. They have often found that hysteria may account for a large proportion of the incapacity in a patient presenting such definite signs of organic disease that it might very easily have been presumed that the entire condition was organic. Hence, every case in which it is at all conceivable that a hysterical element is present is tested by observing the effect of psychotherapy. The subject is discussed fully as to its clinical aspect, and many illustrative cases are cited.

Hysterical Vomiting in Soldiers.—Hysterical vomiting, according to Reynell, is comparatively common among soldiers. Besides being a most distressing condition in itself, it may lead to a severe degree of neurasthenia, with progressive emaciation and increasing mental distress, the loss of appetite with which it is associated finally leading in severe cases to a condition of anorexia nervosa. In many cases it is the only symptom, but the slighter forms of hysterical vomiting are common among patients suffering from all kinds of war neuroses. In a large number of cases, the hysterical nature of the disorder has not been recognized, and the patient has been treated as a sufferer from gastritis. Out of some 400 cases of war neuroses, eighteen patients suffered from hysterical vomiting of from four to twelve months' duration. All of these patients have been cured within three weeks of admission, most of them within ten days, and a few after a single treatment. The treatment used by Reynell for nearly all of these patients has consisted of psychotherapy, reinforced by the suggestive effect of the passage of a stomach-tube.

Hysterical Disorders of Micturition.—The case histories of two patients with hysterical incontinence of traumatic origin and two dating from infancy, together with one case of hysterical retention following injury, are cited by Moore. He believes that these cases were undoubtedly genuine, as shown by the great distress occasioned by the patients and their relief on being cured. Both patients were cured by psychotherapy.

Convulsions in Soldiers.—All cases of hysterical convulsions or fits, according to Gordon, are amenable to cure by psychotherapy. Two methods of treatment may be employed, hypnosis and autognosis. Gordon prefers the latter. By this is meant that the patient is afforded insight into his condition and made thoroughly to understand the pathogenesis of his fits. The patient is aware of what is going on all the time, and is invited and encouraged to cooperate in the treatment by the exercise of his reason and his will.

Dysentery in East Africa. J. C. Watt.—p. 45.
*Peculiar Group of Coccaceae. A. J. Chalmers and R. G. Archibald.—p. 48.

Peculiar Group of Coccaceae: Janus.—Peculiar diplococcal-like or streptococcal-like organisms which contain elements, some of which are frankly gram-negative while others are gram-positive, have been found from time to time by Chalmers and Archibald in the meninges and cerebrospinal fluid of cases of cerebrospinal meningitis, in the nasopharynx of cerebrospinal contacts, on the tonsils of a fair number of cases of severe tonsillitis, and in the blood of one case of septicemia. All these organisms belong to Zopf's family *Coccaceae*, as modified by Migula, and the authors call the group *Janus: Janus anginosus*, found in sore throats, and characterized by fermenting mannitol but not raffinose. *J. crassus*, found in cerebrospinal meningitis, is characterized by not fermenting mannitol and by producing acidity but no gas in raffinose. *J. septicemicus*, found in septicemia, is characterized by producing acidity but no gas in mannitol.

*Movable Bodies in Knee. C. Willems and J. de Caestecker.—p. 585.
*Blood in Serous Cavities. L. Delrez.—p. 602.
*Toxic Action of Blood Transfusion. N. Goormaghtigh.—p. 611.
*Sympathetic Ophthalmia. Van Schevensteen.—p. 621.

Walking at Once After Removal of Movable Bodies in the Knee.—Willems and de Caestecker now have a record of seventeen cases in which after extirpation of movable bodies in the knee they insisted on the immediate use of the knee. They emphasize the absolute absence of injury from early mobilization which was a constant feature of their cases of war wounds of joints, and proved to be the same with these movable bodies. Some of the seventeen patients had considerable pain for a few hours or days and some had a little fever, but there was no infection and the mobilization of the knee was continued notwithstanding. If there was effusion, this was punctured without delay. No treatment was applied except actively moving the knee as soon as the patient roused from the anesthetic, keeping this up until he is walking around which was usually by the third day, sometimes the second day. Several of the men returned in two weeks to their service at the front. This early functional use of the joint is not only superior to all other methods in the rapidity of the cure but in the perfect functional and anatomic results attained. In their later cases they used local instead of general anesthesia for the operation, and they always work through a lateral vertical incision. They found several times more than one movable body, and hypertrophied fatty processes sometimes accompanied a dislocated meniscus. They warn that the mobilization must be active; passive movements are of no use. The joint should be flexed and stretched, as far as possible each time, increasing the excursions, and keeping this up uninterruptedly, to the point of fatigue. Even the timid and cowardly can be persuaded to do this, but it is essential that some person must be by their side continually, reasoning with them, urging, coaxing, insisting, actually nagging them into keeping up the movements of the joint on which its future soundness depends. The result is proportional to the energy displayed by the persuading attendant and the patient himself. The mobilization is not actually painful, in the true sense of the word, even in severely infected cases. In conclusion they remark that a movable body, displaced meniscus or enlarged fatty process may be the true cause of certain chronic and recurring effusions in the joint rebellious to ordinary treatment.

Hemorrhagic Effusions in Serous Cavities.—Delrez' experiments on dogs have confirmed that blood extravasated in a serous cavity becomes promptly coagulated as under other conditions. But the clots act as a foreign body which irritates the serous membrane, and it responds with exudation. Tapping the serous cavity releases merely the serum and the effusion; the clots are left behind to continue their irritating action. No relief is realized until the cavity is opened and the clots removed. In his research on dogs, he introduced one end of a paraffined cannula into the femoral artery, the other end into the peritoneal cavity, thus realizing a hemorrhagic effusion in the peritoneum as much like clinical conditions as possible. The fluid drawn later by puncture resembled that obtained by defibrinating blood; possibly the respiratory movements, etc., may act like the defibrinating technic. He was unable to apply the research to joints, but says that there can be no reason why the conclusions from the experiments on the pleura and the peritoneum of dogs cannot apply equally well to hemorrhagic effusions in joints.

Blocking of the Kidney After Blood Transfusion.—Goormaghtigh reports the case of a man of 23 with a shell wound of the side of the chest. The operation four hours afterward showed that the axillary vein had been lacerated and both the vein and artery were ligated. The pulse kept imperceptible, the general condition bad; the reds numbered only 3,872,000, the whites 43,600, and transfusion of blood seemed indicated. As only one donor was available, no agglutination tests were made of his blood; the Wassermann reaction was negative. The donor was robust but had just returned from a furlough. He was not alcoholic. About 520 c.c. of his blood was injected by the syringe method in the course of twenty minutes. The improvement was remarkable. By the next day, however, serious symptoms developed, including oliguria and anuria, and the man died the fourth day. Necropsy showed important toxic lesions in the liver, kidneys and heart, confirming the clinical picture of acute and fatal uremia which the man had presented. The acute tubular nephritis explained the blocking of the kidneys but the acute toxic lesions in the liver were enough to explain it without this. The donor's blood may have been temporarily toxic on account of excesses during the furlough.

Sympathetic Ophthalmia.—Van Schevensteen reiterates the vital importance of specialist care of all injuries of the eyes. Experience seems to show that if more than two weeks have elapsed since the eye was infected, there is doubt whether its enucleation then will ward off sympathetic ophthalmia. In two cases of declared sympathetic ophthalmia he instilled mydriatics and gave intravenous injections of arsphenamin. The outcome was satisfactory in one case but not in the other, even though mercury and sodium salicylate were given in addition. His article reviews the present status of sympathetic ophthalmia, and gives the detailed differential blood count in several cases. In Morax' compilation of 39 cases. 13 terminated in total or nearly total blindness, one in suicide, and one with vision of only 0.1. In the 26 favorable cases, visual acuity of 0.3 or 0.4 was left in 5 cases; in the others, from 0.5 to 1.0, but in some of these cases vision deteriorated somewhat later.

Bulletin de l'Académie de Médecine, Paris

Feb. 25, 1919, **81**, No. 8

*Phenol Gangrene. R. Le Clerc.—p. 205.
*Hepaticoduodenostomy for Bile Fistula. S. Mercadé.—208.
Operative Treatment of Hemorrhoids. P. Bazy.—p. 211.
*Cancer of Lips and Tongue in Animals. Cadiot.—p. 218.
*Tuberculosis in Colored Troops in France. L. Moreau.—p. 224.

Phenol Gangrene.—Le Clerc declares that in cases of phenol gangrene of the fingers, amputation is formally called for, as otherwise serious septicemia is liable to be entailed. In a case he describes, the woman of 50 had applied a 5 per cent. solution of phenol to her finger, keeping it constantly moist for twenty-four hours. Besides the gangrene, there were hallucinations, excitement and delirium as with high fever, but there was no fever and the pulse was regular and strong when he saw the woman the twentieth day. She died in collapse the second day after this.

Bile Fistula.—In Mercadé's case, the fistula left after a cholecystectomy refused to heal. After waiting three months, the hepatic duct was released from the fibrous mass in which it was embedded, connecting the stomach, liver, colon and duodenum. The common bile duct had retracted until it could not be discovered, and only 1 cm. of the hepatic duct could be released. An anastomosis was made between this and the duodenum, with smooth, permanent recovery.

Cancer of Tongue and Lips in Animals.—Cadiot comments on the extreme rarity of cancer of the lips and tongue in animals. The few cases that have been published were more probably a mycosis or microbic ulcer. He has found only seven cases recorded of actual cancer of the tongue in animals, including three horses, two cats, one dog and one cow. This rarity of cancer in the tongue and lips is most remarkable when we consider the frequent irritation of lips and tongue in horses and in other animals, domestic and wild.

Tuberculosis Among the Colored Troops in France.—Moreau calls attention to the frequency of tuberculosis among the troops recruited among the natives of the French colonies in Africa and elsewhere. The general condition is not notably modified, but radioscopy reveals that they are profoundly infected with tuberculosis. The change of climate and the physical stress of warfare, etc., fan the latent process into a flame. The bronchopulmonary form of influenza also found a favorable soil in them, with rapidly fatal issue.

*Malaria and the Bordet-Wassermann Reaction. S. I. de Jong.—p. 3.
*Exophthalmos in Nephritis. P. J. Rondopoulo.—p. 4.
Influenza at Athens. Sakorrafos.—p. 6.
Paralysis of Last Sixth Cranial Nerves and Cervical Sympathetic Nerve after a War Wound. D'Oelsnitz and L. Cornil.—p. 6.
*Electric Treatment of Hysteric Paralysis. L. Moreau.—p. 10.
*Injection of Air into the Pleura. A. Challamel.—p. 12.

Malaria and Seroreactions.—De Jong emphasizes that the Bordet-Wassermann test reaction is not modified by malaria except during the febrile attacks.

Nephritic Exophthalmos.—Rondopoulo has been examining persons with a tendency to nephritis in order to detect exophthalmos which certain writers say is common with nephritis, while others have never encountered it. He found it in two among fifty-two cases, and says that it seems to average about 3.8 per cent. and to occur in the subacute and chronic cases showing signs of a tendency to uremia. The exophthalmos was of the goiter type, with positive Graefe and Stellwag or Möbius signs in his cases.

Electric Treatment of Hysterical Paralysis.—In Moreau's three cases the functional paralysis or contracture had developed after a burn, or a blow on the chest, or apparently spontaneously. The treatment was with a single intensive application of unipolar galvanization, with a current representing 45 or 50 milliampères and 80 volts. The paralysis was of long standing in two of the cases, rebellious to all previous measures.

Injection of Air Into the Pleura.—Challamel uses a small glass tube with a 6 cm. rubber tube slipped on one end. Some cotton is packed loosely in the other end of the glass tube and the whole is kept in a test tube till ready to use. Then after the effusion in the pleura has been tapped, this glass and rubber tube is interposed between the trocar and the rubber tube connecting with the bulb. The air or oxygen can then be pumped in with confidence that it has been duly filtered.

*Radiography of Fractures of the Pelvis. P. Japiot.—p. 81.
*Malaria in Morocco. L. Langeron.—p. 86. Conc'n.
*Latent Gastric Cancer. C. Dunet and E. David.—p. 98.

Fracture of the Pelvis.—Japiot stresses the importance of radiography in cases of apparently simple contusion; also the necessity for radiography of the two sides for comparison, and calls attention to some possible sources of error.

Malaria in Morocco.—Langeron's experience in Morocco has convinced him that the subcutaneous administration of quinin is usually the only reliable method, and that at least 2 gm. have to be given daily. He has never gone above 3 gm. Certain independent generations of the parasites are developing at different times, without connection with the main paroxysm, and hence the organism should be kept continually under the influence of quinin. He warns of the danger of new inoculation by mosquito bites for persons taking treatment as well as for the cured. The healthy carriers of the malaria parasites form a constant danger, but it must not be exaggerated. The history of malaria in Morocco testifies anew to the advantages of a well conducted campaign against malaria even although conditions there render its total extermination impossible at present.

Clinical Picture of Interlobar Pleurisy Induced by Gastric Cancer.—In the case reported by Dunet and David, the gastric cancer had been entirely latent in the man of 44, the only symptoms being those from metastasis in the lungs causing the clinical picture of interlobar pleurisy. Puncture at the point of the supposed encysted pleural effusion brought merely blood, but necropsy showed the minute gastric cancer and the large generalization of the malignant disease through the left lung.

*Objective Examination with Disease of the Digestive Apparatus. P. Le Noir and M. Delort.—p. 113.
Malaria. H. Gros.—p. 120.
*Medical Inspection of Schools. H. Méry.—p. 123.
Intramuscular or Intravenous Injection of Cherry-Laurel Water in Treatment of Chronic Bronchitis and Pulmonary Tuberculosis. A. Grimberg.—p. 124.
Colloidal Metal Preparations in Influenza. P. Richard.—p. 125.

Objective Findings with Digestive Disease.—Le Noir and Delort devote nearly eight pages to a systematic outline for clinical investigation of the case. In a previous article they outlined the systematic interrogation of the patient. By proceeding as they describe, with a regular system, many instructive transient signs may be detected which otherwise would be lost. They are in charge of a *centre de gastro-entérologie*, and their experience with thousands of cases has confirmed the importance of these minor signs as they describe in detail. By following a regular outline for examination time is saved and nothing is overlooked.

The Work of the Medical Inspector of Schools.—Méry remarks that medical inspection of schools dates at Paris from 1879, but no attempt had been made until the last decade to extend the work of the medical inspectors beyond the defense of the school against contagion. In 1910, the city was divided into 210 medical districts for the purpose of school inspection, each inspector having about a thousand children allotted to him. Each child is soon to have its individual health booklet, to record the results of regular examinations through his entire school life and possibly later. The inspector should record the weight, the height, the chest measure, etc., the spirometer findings, the effect of test exertion on the heart, acceleration of the pulse and arterial tension; also the results of muscular tests with the dynamometer. There should be an obligatory general examination every two years. The inspector should be familiar with the normal standards and the normal development of body and mind, and he should be paid enough so he need not be obliged to regard this school work as merely an accessory to his professional work. The making out of the health booklets and the thorough examination as the child enters school for the first time should be regarded and remunerated as an extra function, aside from the habitual duties of the school physician. His routine duties include prophylaxis of contagious diseases and control of the physical education, and these require an inspection visit to the school once a week or possibly twice under certain conditions. His task might be singularly facilitated by the creation of school nurses.

*Malarial Neuritis. L. Moreau.—p. 145.
*Hip Joint Disease in Soldiers. E. Beaujard and others.—p. 151.
*Essential Incontinence of Urine. Chavigny.—p. 155.

Malarial Neuritis.—Moreau insists that malarial neuritis or polyneuritis is not so rare as generally supposed; he has encountered nine cases himself. There was facial or radial paralysis in two of the cases, and polyneuritis of the arms or legs in others, with or without plantar or facial paralysis. In one case the muscles in the legs had almost entirely wasted away, and the man could not walk without crutches. The prognosis is always grave, but if there are only slight quantitative modifications of the electric reactions, almost a complete cure may be anticipated. Galvanic electric treatment, massage, quinin, arsenic and a change to mountain air aid in recovery or improvement. The quinin helps to ward off the febrile attacks which usually aggravate the nervous disturbances each time.

Deforming Hip Joint Disease in Soldiers.—Beaujard and his co-workers warn that the roentgen rays sometimes explain a soldier's limping as the result of a rapidly developing, deforming osteo-arthritis of the hip joint. The deformity is of several different types, as they explain with radiograms. They query whether it may not be a premature senile hip joint affection. The fatigues and overexertion of the campaign may have brought on premature senility in these tissues. Certain writers have suggested this as the only possible explanation of various puzzling clinical manifestations.

Essential Incontinence of Urine.—Chavigny comments on the fact that surgeons and urologists have been the ones to handle cases of incontinence of urine, and they have patiently sought for organic factors. The most diverse causes have thus been incriminated, and treatment of these causes by widely differing methods has usually been successful. The reason for the success is that micturition is not a spinal cord function as hitherto taught. It is a brain function, although long training has made a subconscious act of it. There is no need to waste time in analyzing the urine, etc., and there is no use in trying to cure the absolutely incurable cases with grave mental impairment. Waking the subject at night is a simple and effectual means for training to overcome the habit. An excellent device for the purpose is to place between the sheets and the mattress, under the buttocks, two flexible metal plates separated by a layer of cotton. This is the interrupter for the current. Two other plates are held on the pubis in the belt of a suspensory. If urine seeps down to moisten the cotton below, the current passes on, and the electric shock not only wakes the incontinent sleeper, but induces immediate contraction of the bladder sphincter. In any event, cases of essential incontinence should be sent to a psychologist rather than to a surgeon or urologist. Soldiers who are too settled in the habit for it to be overcome, might be grouped in a special company so that they need not annoy others. The ridicule on account of belonging to such a company might realize a cure in some otherwise incurable cases.

*Serotherapy of Gas Gangrene. E. Sacquépée and De Lavergne.—p. 85.
*Infectious Processes in the Pleura. J. L. Roux-Berger.—p. 86.
*Grafts of Dead Tissue. G. Bonnefon.—p. 88; J. Nageotte and L. Sencert.—p. 88.

Serotherapy of Gas Grangrene.—Sacquépée and De Lavergne relate experiences with serotherapy in 191 cases of gas gangrene. Recovery ensued in 86.91 per cent. of the cases. In 113 cases the gas gangrene was well under way when serotherapy was begun, but 83.08 per cent. recovered under it. Serotherapy thus has proved useful in both prophylaxis and treatment.

Wounds of the Pleura.—Roux-Berger excises the devitalized tissue when a war wound of the chest has left an infected focus with fistula and an extensive cavity in the pleura. After the pleurectomy, he fastens the lung to the chest wall, in front and back, to keep it expanded, and drains from the rear. He did not lose any of the fifteen patients thus treated, but to relieve the pain and dyspnea he used Crile's anoci-association which seemed to *simplify the after-effects* of the operation.

Grafts of Dead Tissue.—Bonnefont states that in four years of experimental research, using 500 cornea grafts, the transplanted connective tissue always died sooner or later. He disputes the assertions of Nageotte and Sencert to the contrary, but the latter reply that increasing experience has abundantly and repeatedly demonstrated the feasibility of utilizing grafts of nerve and tendon tissue that have been kept in alcohol for some time. These grafts of dead tissue are thus proving a complete success.

*Hysteric Bent Spine. Chiray and E. Roger.—p. 105.
*Traumatic Contraction of Sound Artery. C. Viannay.—p. 106.
Operative Treatment of Traumatic Lesions of the Thyroid. H. Alamartine.—p. 107.

Hysteric Curvature of the Spine and Typhoid Spondylitis.—Chiray and Roger relate some cases in which typhoidal spondylitis merged into hysterical camptocormia. Under the influence of the pains in and around the spine, from the acute spondylitis, the spine is held in a vicious attitude and this persists after subsidence of the acute process. In some of their cases from eighteen months to four years had elapsed without the spine being straightened. The disappearance of tenderness on pressure tells when the spondylitis has become extinct. The interval since there has been any fever is also instructive. Potts' disease can be excluded by the involvement of the body of the vertebra rather than of the intervertebral disk; the nervous reactions are livelier, and paresis and paralysis are common. Typhoid spondylitis never leaves ankylosis. As with all similar contracture, repose in a good attitude is the main thing. The man should stay in bed with continuous extension by weights to the legs, the plane of the bed sloping slightly to the head to ensure counter extension. A plaster corset may be useful at first. Counter suggestion is the only treatment when nothing is left but the hysteric contracture.

Traumatic Contracture of Sound Artery.—Viannay calls this "arterial stupor," and explains it as the reaction to the trauma by the peri-arterial sympathetic nerve. The circulation through the artery persists, but it is reduced to a much smaller stream. Conditions gradually right themselves without gangrene. This arterial stupor seems to be an important factor in the spontaneous arrest of hemorrhage.

*Proliferation of Adipose Tissue in Knee. J. Dubs.—p. 289.
Placenta Extract in Diagnosis of Pregnancy. E. Frey-Bolli.—p. 299.
Colloidal Metals and Fixation Abscess in Influenza. H. Hodel.—p. 310.

Traumatic Proliferation of Adipose Tissue in Knee.—Dubs calls this condition Hoffa's disease, and describes eight typical cases. In only three was the diagnosis made before the operation, but in one of these the diagnosis was unmistakable, the doughy pads each side of the patella being readily recognized. In all the cases there was a history of an accident to the knee a few weeks before. There is usually in the pronounced cases considerable atrophy of the quadriceps, but the use of the knee is not interfered with except for the pains. These are localized in the front of the joint, generally at the inner margin of the patella, but they are never so intense or protracted as with incarceration of the meniscus. The only treatment is by removal of the proliferated fatty processes if simple conservative measures do not prove effectual.

Schweizer Archiv f. Neurol. und Psychiatrie, Zurich

1918, **2**, No. 2

*The Prevailing Psychologic Trend in Psychiatry. E. Bleuler (Zurich).—p. 181.
*Pathologic Anatomy of Nervous System in Epilepsy. M. Tramer.—p. 202.
Psychiatric Analysis of Jean-Jacques Rousseau's Confessions. V. Demole.—p. 270. In French.
*The Spine Reflex. S. Galant.—p. 305.

The Psychologic Trend in Psychiatry.—Bleuler comments on the valuable lessons learned from traumatic neuroses, especially under workmen's compensation legislation. The wish to obtain an indemnity or to escape the horrors of warfare maintains the traumatic neurosis, and he asserts that there is no persisting neurosis except where there is something to be gained by its persistence, even if it is only to show a hated enemy, "See, now, what you have done." Traumatic neuroses following an earthquake promptly subside spontaneously. He does not hesitate to add that certain morbid conditions are iatrogenous, that is, they are bred by the physician, either from ignorance or mistaken zeal suggesting some ailment which the subject does not have, or magnifying a trifle into a serious condition. But these iatrogenous maladies could not develop without a predisposition. Nervous dyspepsia is a prototype of this class of cases. One of his axioms is that excessive zeal for the improvement of the world is a sign of a mental anomaly. "Social and sex questions and the woman question are psychic more than economic problems." "Those are right who say that psychic anthropology is more important than bone measurements."

Pathologic Anatomy in Epilepsy.—Tramer's monograph is based on experiences at the national Swiss institution for epileptics and a cantonal insane asylum. He was unable to find any pathognomonic lesions with epilepsy, but, at the same time, he states that with the severer cases there is great probability that the Betz' cells will show certain changes and that marginal gliosis will be found. Also that the discovery of these morbid changes will afford some probability of a retrospective diagnosis of epilepsy, especially in cases of much mental impairment.

The Spine Reflex.—Galant noticed that stroking along the spine of a quite young infant, held with its abdomen on his left palm, elicited a characteristic reflex movement. It is rapid, and resembles the curving of the body of a lizard as it winds its way rapidly through the grass. The infant keeps this lateral curve for a time. He examined 150 young infants and thirty-six idiots between 7 and 30 years old. The spine reflex occurs more constantly in infants than the Babinski, and is stronger and persists longer. It can be elicited by stroking with the handle of a hammer or by pricking. The reflex movement is so pronounced that the infant is liable to slip off the supporting hand unless one is careful. It grows weaker as the months pass, and it could not be elicited in one 7 months infant. All but one of the 105 infants presented this reflex, but only six of seventeen epileptics, and it was typical only in one in this group.

Gazzetta degli Ospedali e delle Cliniche, Milan

Jan. 30, 1919, **40**, No. 9

*Intestinal Lambliosis. M. Mantovani.—p. 66.

Lambliosis.—Mantovani never found dysentery traceable to the lamblia, but there was always diarrhea in the cases of lambliosis he has encountered. It evidently has some pathogenic power, inducing a proteiform set of symptoms up to ulceration in the rectum, but the subacute enteritis shows nothing characteristic. There is no specific treatment, but arsphenamin has the best record, not from any direct action on the lambliosis but by improving the general condition. One man, in robust health otherwise, had occasional attacks of colic, the pain above the umbilicus, with tenesmus and diarrhea up to thirty or forty passages a day, with eosinophilia of 10 per cent., and the lamblia in the stools. One woman of 50 with severe diarrhea for three months, rebellious to all treatment, with enormous numbers of the lamblia in the stools, and 8 per cent. eosinophilia, succumbed to progressive debility. Her brother had died not long before after several months of a similarly protracted and rebellious diarrhea, with the lamblia in the watery stools.

Feb. 2, 1919, **40**, No. 10

*Sputum Vaccine in Pneumonia. G. A. Pari.—p. 73.
*The Epidemic of Influenza. C. Mannini.—p. 76.
*Para-Influenzal Paralysis of the Heart. A. Tomaselli.—p. 7[illegible]

Sputum Vaccine Therapy [illegible] neumonia. [illegible] ere reports add [illegible] is p [illegible] tements as to the therapeutic efficacy of a vaccine made from the mixed sputa of twenty patients with influenzal bronchopneumonia. He now has a record of thirty-one cases and styles the results very encouraging. He sterilizes the pyovaccine, as he calls it, in the autoclave.

Influenza.—Mannini describes a number of nervous and psychic symptoms observed in the inmates of an insane asylum when influenza swooped down on it; 87 per cent. developed the disease, and the heart in a number showed marked disturbance. Tomaselli describes four cases in which the patients succumbed to paralysis of the heart when they were apparently far along in convalescence from influenza.

Policlinico, Rome

March 9, 1919, **26**, No. 10

*Streptococcus Pandemicus. M. Segale.—p. 289.
*Correction of Ankylosis of Knee. U. Camera.—p. 290.
*Iodin in Treatment of Goiter. A. Pennisi.—p. 296.
Abuse of Iodin in Treatment of the Throat. G. Bilancioni.—p. 300.

Etiology of Influenza.—Segale's later experimental research apparently confirms the etiologic importance of the streptococcus which he has cultivated from influenza cases and which reproduces a similar set of symptoms when guinea-pigs are inoculated with it on the nasal mucosa. He is convinced that this *Streptococcus pandemicus* is something new; others have cultivated the same germ in the present pandemic. The animals died when inoculated even with cultures that had been passed through a Chamberland filter. Hemorrhagic effusions were found in the peritoneum and lungs, with marked congestion of the respiratory apparatus. The same findings were observed in guinea-pigs treated with the filtrate that had been heated to 55 C. for an hour.

Simple Method for Traction on a Stiff Knee.—When the ankylosis is not due to the bones, Camera corrects it by placing the heel on another table as the patient reclines with the trunk on bed or table. The leg thus forms a bridge, and he ties a pail to the knee so it hangs a little below the knee. By filling the pail with water, the weight can be graduated to induce the traction desired. This slow, gradual, gentle traction usually accomplishes the reduction in a single sitting; at most in two or three, and the correction can be maintained in a plaster dressing.

Goiter.—Pennisi made local and general injections of Durante's aqueous iodin potassium iodid solution, in a strength of 1 or 2 per cent. in treatment of goiter. In three of four cases described, the cystic and parenchymatous goiter subsided completely. In the other case, the goiter subsided but returned during a pregnancy soon after. Probably resumption of the treatment would have a favorable effect now. In three cases of exophthalmic goiter the condition improved materially under the same treatment, but the other measures taken at the same time may have been responsible for this. In any event, the iodin did no harm.

February, 1919, **26**, Surgical Section No. 2

*Treatment of Chronic Osteomyelitis. L. Franco.—p. 49.
*Traumatic Lesions of Yellow Spot. G. Ricchi.—p. 60.
*Appendicitis Complicating Movable Kidney. S. Rolando.—p. 68.
*Projectile in the Heart. I. Scalone.—p. 71. Cont'n.

Chronic Ulcerating Osteomyelitis.—Franco lauds the fine results realized with Durante's method of clearing out the focus into sound tissue, leaving a bowl shaped cavity. A square flap cut in the adjoining tissues, either skin alone, or skin and muscle, or skin, muscle, periosteum and bone, according to the circumstances, is twisted around and fitted in the gap, after the latter has been treated with iodin. The flap is held in place with one or two small nails, and a lightly compressing bandage is applied. No suture, no tamponing, no draining. The dressing is not changed until the fifth day. By the seventh or eighth day the flap has become adherent and the nails can be taken out. Sixteen cases are described in detail with illustrations of four, showing the prompt and radical cure of processes which had dragged along for months, rebellious to all other measures. This method was first applied by Durante, April 2, 1917, but in 1896 he published experimental research demonstrating its feasibility. The war brought the opportunity to apply it in practice.

Trauma of the Yellow Spot.—Ricchi reports that in two of his six cases the injury of the macula lutea was not accompanied by other lesions. Some were war and some industrial accidents. The course and outcome are described in detail.

Appendicitis as Complication of Movable Kidney.—Rolando relates that in the twenty-five cases in which he has done nephrectomy on the right side, there were signs of appendicitis only in three. The pain induced by the movable kidney may be mistakenly ascribed to the appendix when the latter is quite sound. When it is possible to draw the appendix out through the lumbar incision for the operation on the kidney, the probabilities are that the appendix is sound. Inflammatory adhesions would make it impossible to draw up the appendix in this way.

A Projectile in the Heart.—Scalone quotes D'Antona to the effect that sometimes one is more truly a surgeon when he does not operate than when he does. This applies particularly to a bullet in the heart when it seems to be borne without disturbance, as in a case described in detail. His experimental research on large, robust dogs, showed that adhesions developed or not directly proportional to the amount of inflammation accompanying the wounds.

Riforma Medica, Naples

Granulations in the Lymphocytes. A. Ceconi.—p. 146.
Factitious Bladder Stones. C. Guarini.—p. 148.
*Induced Pneumothorax. G. Cicconardi.—p. 150.
Prophylaxis of Buccal Disease. B. De Vecchis.—p. 152.
*The Nervous System in the Tuberculous. A. Ferrannini.—p. 153.

Induced Pneumothorax with Hemoptysis.—Cicconardi states that when the hemoptysis is extensive, the hemorrhage issuing from an actual tear in some vessel in the lung, then prompt resort to artificial pneumothorax may save the otherwise doomed patient. It is indispensable to locate the injured vessel by the localized pain, gurgling sounds, râles at the base, etc. The needle is introduced in the third or fourth intercostal space, between the mamillary and anterior axillary lines. From 800 to 1,000 c.c. of nitrogen or oxygen or air are introduced, and more is introduced every four or five days to maintain the compression on the lung. The hemoptysis is usually arrested at once; only rarely is a second intervention of the kind needed in twenty-four or forty-eight hours. The use of the manometer has reduced to zero the danger from an artificial pneumothorax, while it is an efficient adjuvant in treatment of the pulmonary process as a whole, and not merely the bleeding vessels, he reiterates in conclusion.

The Nervous System in the Tuberculous.—Ferranini remarks on the rapidity of the reaction to stimuli of different kinds in the tuberculous, demonstrating the extreme excitability of the nervous system. The reaction is not only exceptionally prompt but it is also exceptionally intense, and it reaches its maximum sooner than under other conditions. On the other hand, the reaction is exhausted sooner, and the tonic capacity is less. Various laboratory instruments record these findings, showing the "impulsive" character of the reactions in the tuberculous, along with their hypotonic and hyposthenic character, as an aid in differential diagnosis. The toxins are responsible for this extra excitability of the nerves, and this in turn affects the endocrine system, or vice versa, with a resulting vicious circle. To this must be added toxic irregularities in growth, especially of the nervous system. For example, the normal growth of the brain may be exaggerated, and it may pull up the spinal cord and its roots, and this ascension of the cord may be rendered more injurious by an exaggerated growth of the vertebrae. The spinal roots then are stretched and compressed, with obvious injury. Such findings in the young may turn the scale in dubious cases. Even in adults, they may give the clue when we reflect that with advancing age the nervous system normally tends to display just the opposite characteristics. Irritable weakness at any age should warn of possible tuberculosis.

Rivista Critica di Clinica Medica, Florence

*Cancer of the Ampulla of Vater. A. Ristori.—p. 25.

Cancer of Ampulla of Vater.—Ristori was impressed by the greenish brownish jaundice of the man of 62, while the presence of urobilin in the urine and of stercobilinogen and stercobilin in the feces testified that the obstruction of the common bile duct could not be complete. The liver and gallbladder were enormously enlarged; the pancreatic duct seemed to be freely permeable. A vague painfulness in the region of the lower end of the common bile duct had preceded the jaundice and this, in connection with occult blood in the stools, confirmed the assumption of cancer on or near the ampulla of Vater, revealed later by necropsy.

Jan. 25, 1919, **20**, No. 4

*Neuroses of the Heart. A. Sbrocchi.—p. 37.

Cardiac Neuroses.—Sbrocchi emphasizes the diagnostic importance of the absence of symptoms from any other organs when the disordered heart action is due to a neurosis, while signs of a tendency to nervousness are marked. The most important are tremor of the eyelids when the eyes are closed, tremor of the fingers when the hand is extended and the fingers spread, a sensation of heat in the ears, cold hands and feet, dermographism, and exaggerated reflexes in general. Among the further testimony to the nervous character of the heart disturbances is the attenuation of the conjunctival and pharyngeal reflexes. The subjective symptoms show nothing characteristic.

Archivos Españoles de Pediatria, Madrid

January, 1919, **3**, No. 1

*Pseudotumors in the Brain. L. Morquio (Montevideo).—p. 5.

Pseudotumors in the Brain.—Morquio refers to the clinical picture in children which seems to indicate a tumor in the brain, but the gradual subsidence of all symptoms or the necropsy findings disprove this diagnosis. He reports six cases in detail. The youngest child was 3 and the oldest 12 years old. A trauma was incriminated in two cases; one child gave a positive response to the Wassermann test. The headache was not continuous, but occurred in paroxysms, very seldom severe enough to make the children cry or complain. The attacks lasted a few hours or days followed by periods of calm. In some it was occipital, in others frontal, in still others the headache was diffuse. In some it seemed to be relieved by vomiting. As a rule, the headache came on as the children got up in the morning, but sometimes it appeared without any regularity but more commonly after eating. Some of the children had pain on pressure of the skull over the frontoparietal groove. At necropsy of one child with intercurrent diabetes insipidus, who had succumbed to cachexia, nothing suggesting a tumor was found to explain the symptoms during life except a focus of softening in one peduncle. The experiences related justify trephining in cases of apparent brain tumor in children. If this relieves and the symptoms show a tendency to retrogress, the operation can stop there. This alone would arrest and possibly cure the pseudotumor disturbances. If there is an actual tumor, the operation can be completed later, although, Morquio adds, the outcome is almost inevitably fatal, even in cases of simple hydatid cyst. The complete syndrome of a brain tumor in a boy of 12 kept up for four years with intermissions and intermittent otitis and final tuberculosis. Necropsy failed to disclose any tumor in the brain. The youngest child died five months after a negative operation for supposed hydatid cyst. The brain symptoms had entirely retrogressed after the operation but returned in an acute form five months later. No necropsy. The negative operation for a mistakenly assumed hydatid cyst proved fatal in one girl of 9 with hemiplegia and aphasia. Nothing to explain the hypertension and paralysis could be discovered at necropsy. In the sixth and last case, the boy of 9 with the complete clinical picture of brain tumor and optic neuritis was taken into the hospital for study of the case. He acquired a mild typhoid, with a relapse, and as this subsided all the brain symptoms disappeared with it to complete recovery.

*Disordered Heart Action in the Obese. A. Mac-Dowell.—p. 25.
*Caustic Treatment of Epithelioma. C. de Rezende.—p. 28.

Disordered Heart Action in the Obese.—MacDowell reviews the literature on disordered heart action with obesity, and analyzes its mechanism. His conclusions are to the effect that the different forms of disturbance, insufficiency of either ventricle, or of the auricles, or a combination of these are due more to some upset in the endocrine system than to the lesions in the heart itself from the tendency to fat production. The endocrine disturbance is responsible for the obesity in the first place, and also for the disordered heart action.

Caustic Treatment of Epithelioma.—De Rezende's success with a caustic mixture in treatment of superficial cancers was mentioned in THE JOURNAL, Aug. 24, 1918, p. 694, and the formula for his mixture was given. He here gives photographs of another case in which it proved equally successful, the epithelioma on the cheek, near one nostril, rapidly subsiding to an apparently complete cure under eighteen applications of the mixture at five day intervals.

*Tetanus. F. Eguia.—p. 244.

Circular Clamp.—Finochietto here concludes his study of modern surgical clamps, etc., by presenting a model of his own devising which, instead of crushing the stump flat, squeezes it into a small cylindrical shape, no larger than the appendix. One of the numerous illustrations shows a part of the stomach crushed thus into a small cylinder, with a clip clamped on at each end of the cylinder. The cylinder is then cut between the clips and the stump can be buried like the stump of the appendix.

Pylorectomy.—Allende gives an illustrated description of Polya's method of pylorectomy, and states that his numerous experiments on the cadaver have confirmed its superiority over other technics.

Tetanus in Infant.—Eguia gave tetanus antiserum freely to the infant that had developed tetanus when 10 days old. He injected 10 c.c. of the antiserum, giving 0.10 gm. chloral by the mouth, and tepid baths, keeping the head cool, every two hours. The mother's milk was fed by the spoonful every three hours, and the umbilical cord was kept moistened with the antiserum. Orders were given to administer 0.25 gm. chloral in an enema every three hours in case of difficulty in swallowing. During one very severe paroxysm he gave chloroform and oxygen. The child recovered after a long and severe siege of the disease. It had been given in the course of eighteen days 140 c.c. of the antiserum, and was able to nurse by the mouth by the nineteenth day.

Automovement. A. S. Herrero.—p. 108.
Alcohol as Factor in Cirrhosis of Liver. F. F. Martinez.—p. 109.
Infectious Jaundice. M. Vilá.—p. 110. To be continued.

Obstruction of Common Bile Duct.—Blanc Fortacin asserts that in all his operations on the bile ducts he has been constantly impressed with the disadvantages and the dangers of the expectant treatment that has been applied before the patient is referred to the surgeon. The condition has been allowed to go from bad to worse under this excessively prolonged expectant treatment, adhesions given time to develop, and inflammatory processes around the liver, etc., rendering the operation far more difficult and dangerous. The gallbladder is generally in such a morbid condition in cases of cholelithiasis that its functional capacity is negligible, and hence its removal can do no harm while this does away with the source of production of gallstones.

Hyperthyroidism.—Bonilla expatiates on the forms of hyperthyroidism apart from exophthalmic goiter, especially the form which accompanies ovarian insufficiency at the time of the menopause. Cold, sweaty hands are a sign of ovarian insufficiency, indicating vasomotor disturbance.

*Malaria in Weltevreden and Batavia. M. L. van Breemen.—p. 1.
*The Mosquitoes of Java. R. M. Mangkoewinoto.—p. 41.

Malaria in Java.—Van Breemen conducted a thorough census throughout Weltevreden and Batavia to determine the prevalence of malaria. The most convenient method for doing this was by examination of the spleen of children between 2 and 12. The palpation was done in the recumbent position, with drawn up knees, and the child was promised a penny after the examination. Each child examined was marked on the stomach with silver nitrate. In this way 14,000 children were examined in a native population of 180,000. The incidence of enlarged spleen is shown on maps in small circles containing a black sector, with an angle of at least 3.6 degrees, representing the percentage of the spleen index. The districts near the sea and where there are artificial fish ponds are conspicuous by the entirely black circles, showing 100 per cent. spleen index. As postmortem examination is obligatory at Batavia, the chart showing the mortality may be regarded as correct, and the mortality figures correspond closely to the spleen index. The report is in parallel columns of Dutch and English. It concludes with a study of the eleven species of anophelines mosquitoes found in the region. The creation of artificial fish ponds has been advocated by the government, and they have been useful in supplying an excellent food, but the mosquito nuisance from them is such that Breemen thinks they have done more harm than good.

Mosquitoes in Java.—The seventeen varieties of the anophelines and their larvae found in Western Java are described in detail, with illustrations and accounts of their habits.

Tertiary Erythemia in Child with Congenital Syphilis. H. Boas.—p. 41.

Surgical Lesion from Ascaris.—Møller's patient was an infant of 22 months under treatment for ascarides. In one week he passed seventy. Then symptoms of peritonitis compelled laparotomy, and an ascaris was found in a pus pocket, but this pocket was encapsulated and there was no peritonitis. The toxic effects of the masses of ascarides were long felt. He was brought back to the hospital four months later with further masses of ascarides. A second course of santonin has apparently banished them completely.

Jan. 15, 1919, **62**, No. 3

*Anemia with Leukemia. C. Gram.—p. 77.

Leukemia with Anemia.—In the first of Gram's two cases, the man of 66 presented lymphatic leukemia with enlarged spleen and anemia of the pernicious type, but no enlargement of lymph glands. The second patient was a young woman with the same clinical picture plus enlarged lymph glands. Treatment in the first case was with repose, iron and arsenic, and two courses of roentgentherapy. Under this the condition has kept fair during the year to date. As the man feels well he has not returned for examination, but has kept up his iron and arsenic pills. The spleen is still two fingerbreadths below the umbilicus, but it does not feel as hard as the year before. The young woman died; the leukocytes in this case showed rapid and remarkable fluctuations, the numbers varying from 326,000 to 2,100.

*Primary Syphilis. H. Haxthausen.—p. 217.
Spontaneous Delivery of Pedunculated Uterine Fibroma: Two Cases. J. Bichel.—p. 226.

Primary Syphilis.—Haxthausen concludes from his experience with 200 cases of syphilis in the primary stage that treatment must be with large doses of arsphenamin, beginning with a full dose at the first injection, and concluding the arsphenamin course with an intramuscular injection. Mercurial treatment must be energetic and prolonged. These principles have given uniformly good results in his experience. The number of injections of the arsphenamin and the period of the infection—within the limits of the primary phase—are of less importance than generally supposed.

THE VALUE OF BIOLOGIC PRINCIPLES IN SURGICAL PRACTICE *

J. SHELTON HORSLEY, M.D.
RICHMOND, VA.

It cannot be too often emphasized that surgery should be more a science than an art. A surgeon who is a dexterous operator and who skilfully amputates a leg that with patience and scientific application could be saved is merely a good artisan, and is distinctly inferior to the surgeon who could save the leg even though he should be a bungling operator. The ideal is to be thoroughly imbued with the principles of the biologic sciences, thoughtfully to apply these principles, and at the same time to be mechanically skilful.

The science of anatomy is essential to the mechanics of surgery. He would be a poor locomotive mechanic who did not understand the construction of his engine; and in operations on the neck, for instance, a surgeon who is ignorant of anatomy would be like the proverbial bull in a china shop. A knowledge of anatomy is essential to good surgery, but in the ever shifting problems of tissue repair and metabolism, physiology is just as necessary. The principles underlying an operation are correct only if they conform to the laws of physiology and of repair of the tissue or organ that is affected. If we could get away from blindly following what some one says merely because he says it, and do things because of reasons that have sound biologic foundations, we should undoubtedly do work more satisfactory to our patients and to ourselves.

HYPEREMIA

Let us take an illustration from the practical work of a surgeon and see how thoughtful application of physiologic principles would have rendered a problem that appeared difficult more easy to solve: Hyperemia is connected in one way or another with all surgical questions, whether they concern treatment of inflammation or repair of a wound. It has long been known that blood is an enemy of the tubercle bacillus, and that obtaining a good supply of healthy blood is the only method of combating tuberculosis. About two decades ago when a patient with tuberculous peritonitis and ascites sought surgical treatment he might have been subjected to one of several procedures: One surgeon would have advised opening the abdomen and letting the sunlight in. Another thought it was best to dust the intestine with some special powder. Still another believed in drainage with a single tube, others with multiple tubes. All these methods secured more or less satisfactory results. Each surgeon, seeing his patient recover after using his own method, earnestly thought that this was the only correct procedure. The situation resembled very much that described in a poem in an old school reader in which four blind men went to see an elephant. One fell against its side and thought the elephant was like a wall; another embraced its leg and declared it resembled a tree; the third grasped its tail and said the animal was constructed like a rope, and the last felt its tusks and concluded that the elephant was very like a spear. The moral was that though each was partly in the right they all were in the wrong. So all these surgeons who were using different methods were unconsciously working on a principle that produced hyperemia, and it was this hyperemia, induced partly by draining off the fluid and so relieving pressure and partly by handling the intestine, that cured the tuberculosis. It was many years, however, before this fact was acknowledged by the various partisans.

The surgical treatment of slow or threatened gangrene has also been much discussed. Carrel and Guthrie,[1] after two experiments, concluded that the blood circulation in the leg of a dog could be completely reversed within six hours. They severed the femoral artery and vein just below Poupart's ligament and united by suture the cardiac end of the artery to the distal end of the vein, and the distal end of the artery to the cardiac end of the vein. After a few hours, when red blood was seen returning, they assumed that the circulation was reversed. I think it can now be stated, however, that it is impossible to reverse the circulation in this manner. In a series of experiments which have been reported elsewhere,[2] we have shown that when the severed femoral artery and vein of animals are sutured together in a reversed direction there is no real reversal of the circulation, and the arterial blood never goes more than a short distance below the knee and is then quickly switched back to the iliac veins through the dilated collateral vessels. Evidently what happened in Carrel's experiments was that dissection paralyzed the vasoconstrictor nerves, and the dilated capillaries permitted red arterial blood to flow through unchanged. When the sciatic and crural nerves are divided in a dog, red blood appears in the femoral vein because of the extreme dilatation of the capillaries. Clinically this is often seen to follow an application of the elastic tourniquet which, if left on for even a short time and removed, produces an intense flushing of the limb until the temporarily paralyzed vasoconstrictors have resumed their function. Many useless operations have been done attempting so-called reversal of the circulation in

threatened gangrene. The only good accomplished was damming back the venous blood and forcing the small amount of arterial blood that reached the tissues to stay longer than it normally would and so deliver to the tissues more nutrition than would be possible when the arterial blood was quickly drained off by unobstructed veins. This can be very simply effected by ligating the femoral vein.

SURGERY OF GASTRO-INTESTINAL TRACT

Surgery of the gastro-intestinal tract suffers from the lack of application of physiologic principles. Take, for example, the popular operation of gastro-enterostomy. It does relieve the symptoms of many patients with duodenal or gastric ulcer. The unfortunate minority, however, that we would like to forget still have their symptoms, and restoration of the normal channels by undoing a gastro-enterostomy is an operation not infrequently performed. The cases that are cured by gastro-enterostomy have never been fully explained. Some say it is a drainage operation, and yet in draining other hollow viscera we do not open at the lowest point. We drain the gallbladder and the urinary bladder from the part opposite the most dependent portion, and we do an enterostomy in the distended loop of bowel that is nearest the incision, because we know that normal contraction or peristalsis will keep the bladder or bowel empty if an opening is made. By some it is claimed that gastro-enterostomy cures because the acidity of the gastric juice is lessened, and still others assert that by short circuiting the course of food, rest is given the ulcer; yet roentgenoscopy reveals that unless the pylorus is closed a considerable portion of food continues to go by this route, and no pyloric closure seems to be permanent unless a resection is made.

PERISTALSIS

Recent physiologic research by Cannon and Washburn,[3] which has been confirmed by Carlson[4] and others, has demonstrated that the hunger pains, or so-called pangs of hunger, in a normal stomach are due to excessive peristaltic contractions of the stomach. It has also been shown that the pains that come on with clocklike regularity after meals in duodenal or gastric ulcer are not produced by acid erosion of the ulcer by the hyperacid gastric juice, as was formerly taught, but are due to contraction of peristalsis on gastric nerves made sensitive by the inflammation of the ulcer. The character of the gastric juice has nothing to do with the pain except so far as it excites an abnormal amount of peristalsis. Food or sodium bicarbonate lessens peristalsis for a while and so relieves pain. Recent investigation seems to show that the stomach has a limited supply of nerves that conduct pain,[5] and these nerves, which are deep in the stomach wall, are made more sensitive than normal by the inflammation around an ulcer. Consequently, they register impulses of pain from the pressure of peristalsis that in a normal physiologic condition they would not register.[6] *It is probable that gastro-enterostomy relieves pain by facilitating the emptying of the stomach and so lessening peristalsis.* This, however, is largely the treatment of a symptom and not an effort to remove a pathologic condition and to restore tissues to their physiologic state.

In surgery of the intestine, the work of Cannon and Murphy in their studies of peristalsis after resection of the bowel has not received proper attention. Lateral anastomosis is still the method employed by many surgeons though, as shown by Cannon and Murphy,[7] peristalsis is practically abolished in the region of such an anastomosis. Food can be pushed through only when a column of it extends into a proximal (oral) loop where peristalsis is unimpaired. Postmortems in dogs with lateral anastomosis showed that there was always an accumulation of food at the site of the lateral anastomosis even when the rest of the intestinal tract was free, because severing the circular fibers, in this operation, abolished peristalsis, and the blind pouches could not be completely emptied. They found that in an end-to-end union there was not the slightest stasis of intestinal contents at the site of operation. Merely because the lateral union usually gives no disagreeable symptoms, its use has been continued. If the patient did not die it was assumed that he had sufficiently recovered. With attention to the triangular mesenteric spaces and careful closure of these and of other raw surfaces before the bowel is opened, together with disinfection of the bowel ends after opening, as good technical results are obtained in end-to-end union as after the lateral method, with the advantage of securing normal peristalsis and normal emptying.

SURGICAL DRAINAGE

One of the common problems in surgery, and a most interesting one, is surgical drainage. This question has revolved around the mechanics of drainage and what material to use, as well as when to drain; but the manner in which drainage acts has been largely disregarded. In surgical drainage, mechanical measures that are followed by fortunate results would appear ridiculous when no biologic problems exist. In preventing infection of a raw surface while draining a deep abscess, gauze is often placed over the raw surface. If we could convert this into a mechanical proposition and imagine that the pus was a solution of methylene blue and that it was flowing over this raw surface which had been covered with absorbent gauze to prevent contamination, we know that both the gauze and the wound would be deeply stained. However, this method of protection does act in a beneficial manner, and a wound is often by this *means* kept from septic infection. The drainage of a peritoneal abscess is practically always up hill, and is usually successful. If mechanics were the only principle, how could an appendical abscess ever be drained by putting a tube down to it through an abdominal incision? The whole method of drainage really depends on a reversal of the circulation in the local lymphatics and is chiefly a biologic process. It is nature's effort to extrude a foreign substance.

If a boy sticks a splinter into his toe and mild infection occurs, the sore "runs" seropus for many days. Finally, the splinter "works" to the surface and is removed. The next day drainage stops and the wound rapidly heals. The splinter has been washed to the surface by the reversed lymph current in an effort to extrude this foreign substance. After the splinter has been removed there is no stimulus for any further extrusion, the lymph current resumes its normal direction, and the wound closes.

[7] Cannon and Murphy: Ann. Surg. **43:** 519-520.

In drainage of the abdominal cavity, where there is an enormous lymph space and where lymph is abundantly poured out, the effort to extrude a foreign body, which in this case would be a drainage tube, causes an immense flow of lymph that carries through the tube much of the septic products that would otherwise have been absorbed. Drainage, then, prevents positive pressure in the suppurating cavity and at the same time has the equally important function of being a stimulus for a reversal of the lymphatic circulation. When a wound is packed with gauze, the gauze acts as a foreign body; and instead of the wound absorbing the pus with which the gauze is saturated, the tendency is for the lymphatic circulation to be reversed, and for lymph to be poured out into the gauze in an effort to wash it away. Portions of the body in which the lymphatic supply is not so abundant as in the abdomen will require dependent drainage because there is not enough lymph constantly to flush out the septic cavity, and gravity must aid. The beneficial action of the cigaret drain, which is clogged with coagulated lymph in a few hours, becomes comprehensible when we view it as an exciting cause for reversal of the lymph circulation.

NEUROLOGIC AND BONE SURGERY

There are many problems in neurologic surgery which require some knowledge of physiologic principles in order to be settled satisfactorily. Spiller and Frazier have demonstrated that section of the posterior sensory root of the gasserian ganglion produces what is called "physiologic extirpation" of the gasserian ganglion. It has been known for years that a nerve which is injured on the central side of its ganglionic cells does not regenerate; yet when the operation of division of the posterior sensory root for tic douloureux was suggested, it was received with some skepticism. This operation is safer than surgical extirpation of the gasserian ganglion, and is followed by less trophic disturbance.[8] The plugging of foramina in the skull from which neuralgic sensory nerves have been removed in order to prevent regrowth of the nerves has sometimes been done with metal screws. Because an iron screw can stop a hole in a piece of wood is not necessarily a reason why it should be employed in living tissue. On the other hand, some substance that does not cause reaction in bone is preferable. What happens after an iron screw is applied? Nature in an effort to extrude the irritating foreign substance removes lime salts in its neighborhood, the bone softens, the screw becomes loose, and the nerve can grow around it.

The fashion for plating fractures fortunately is on the decline. Hundreds and probably thousands of fractures have been plated with heavy metal plates for no reason except that it appeals to the mechanical sense and because some eminent surgeons advocated this operation. In many cases it is followed by attempted extrusion of the plate and, like the splinter in the boy's toe, the plate has to be removed. To the casual observer it seems strange that permanent union does not always occur when a nice cabinet joint is made between the ends of a fractured bone and the ends are held securely in position by steel plates and screws. The same process goes on here as when an effort is made to plug a foramen in the bone with iron. The iron is an irritating foreign substance, and in order to extrude it, nature causes an absorption of the lime salts. As a result, a screw which may at first be firmly fixed in the bone soon becomes loose. But more important is the fact that osteoporosis is induced in this effort at extrusion, and callus formation is thereby prevented or retarded. A poorly fixed fracture without the use of metal is more likely to give eventual good results than the neatest union by means of heavy plates and screws.

EFFECT OF EMOTIONS

That emotions have considerable bearing on the prognosis in certain cases of surgery has long been accepted. Cannon[9] has demonstrated that fright or profound anxiety causes a stimulation first of the sympathetics and then of the suprarenals. The action of epinephrin amounts to a prolonged stimulation of the sympathetic nervous system. Thus the body is put on what may be called a war basis, the circulation is more active, the heart beats faster, the pupils are dilated, respiration is accelerated, and metabolism generally is increased. Often there is so much glycogen released from the liver as to cause marked glycosuria, especially if the body is at rest; but if the emotions are accompanied by physical action, as fighting or running, this excessive amount of sugar may be consumed. The moral is that in some surgical cases it undoubtedly makes the prognosis better if emotions of fear or anxiety are allayed as much as possible. In diseases such as exophthalmic goiter, measures that abolish or diminish fear or excitement are of the greatest importance.

TRANSPLANTATION OF ORGANS

Skin grafting and transplantation of organs or tissues are dependent on biologic laws. Surgeons who have had great experience in this type of work, such as Lexer[10] and Davis, believe that skin grafts from others than the patient are practically never permanent. They either melt away at once or, if they appear to "take," are later absorbed and replaced by connective tissue. It has been suggested that tests, as for transfusion of blood, would be of benefit in selecting a donor for skin grafting; but so far this has not been put to any extensive practice. The transplantation of highly developed organs, such as a kidney, from one animal to another, even if of the same species, is always a failure. The kidney may functionate for a while, but the fine biologic differences in the body fluids of the donor and the recipient cause degeneration, and the kidney eventually becomes a mass of connective tissue. This has been acknowledged by Carrel, Guthrie and others who were at one time enthusiastic about the success of such a procedure. The reconstruction of channels, as the bile ducts, from tissues that have no immunity to the irritating discharges with which they must come in contact is also unwise. Operations in which strips of fascia, pieces of vein,[11] and other tissue unaccustomed to the action of bile are used ultimately result in failure, no matter how skilfully the mechanical part of the operation is done.

CONCLUSION

These are merely a few instances of what every surgeon sees in his work, and they illustrate the profound influence that the application of biologic principles has on surgical practice. Real progress in surgery lies not so much in cultivating the art of surgery and in striving after mechanical dexterity, which is important but can be acquired in a few years, as in the study of biologic principles that concern function, nutrition, metabolism, and repair of tissues, and in the thoughtful application of these principles to every operation and to every method of surgical treatment.

A CASE OF TETANUS ILLUSTRATING MODERN METHODS OF TREATMENT

M. S. WOOLF, M.A., B.Sc., M.R.C.S. (Eng.), L.R.C.P. (Lond.)
Resident Surgeon, University of California Hospital
SAN FRANCISCO

During the past four years, thousands of cases of tetanus have been treated with varying degrees of success. But there is still doubt in the minds of many as to the efficiency of antitetanic serum as a therapeutic measure.

Since the causative organism of the disease is anaerobic, it is probably most toxic when excluded from oxygen either by being in the deep tissues of the patient or in combination with anaerobic organisms, such as *B. subtilis* or *B. pyocyaneus,* which will exhaust any supply of oxygen present. *B. tetani* may be cultivated, however, in increasing supplies of oxygen until it finally loses its virulence. It may be locked up in a healed and therefore sealed wound for months and regain a practical toxicity during the advent of pyogenic organisms to a new wound, operative or otherwise, when tetanic symptoms disappeared months before; or, indeed, after no previous signs of tetanus had manifested themselves. A case[1] has occurred in which, 200 days after injury, an operation was performed for bone grafting. Six days after this, tetanus set in and three days later the patient was dead.

REPORT OF CASE

History.—A boy, aged 16 years, while in company with three other boys, Oct. 17, 1918, hunting ducks with No. 12 gage shotguns, was accidently shot in the left thigh at a distance of 2 or 3 feet. He was taken to the Monterey Peninsula Hospital, where he was treated. On the tenth day he showed the first signs of tetanus. (This is a common lapse of time before the appearance of symptoms.) It is said that 25,000 units of antitetanic serum were given before he came to us, November 3; that is, seventeen days after injury and seven days after tetanic symptoms were first noticed.

The boy himself said he first noticed stiffness in his back and then his jaws felt locked. His teeth were "so tight that he could take food only through straws." He bit his tongue several times when his teeth came together, and evidence of this he had on admission.

He arrived at the University of California Hospital with marked trismus, retraction of head, gross Kernig sign, opisthotonos, boardlike abdomen, generalized contracture of body muscles and a fine risus sardonicus, a late and serious sign of the disease. His body was profusely perspiring, his respirations rapid.

Physical Examination.—Seventeen days after the original injury, on the outer and posterior aspect of the left thigh at the junction of the upper and middle thirds, there was an irregular quadrilateral area, 16 by 8 cm., from which the skin was denuded, exposing the muscular tissue. It appeared to be a surface wound, healthy red in appearance and almost flush with the skin. Roentgenoscopy disclosed about fifty small shot scatered about the femur at this level. There were markedly enlarged, discrete, painless glands in both groins. The jaws could not be opened more than 0.75 cm. between the incisors. The constantly recurring convulsions, which threw all the muscles of the body into tonic contraction at regular intervals, whereby the opisthotonos and the risus sardonicus were emphasized, were extremely distressing to the patient. In the intervals his respirations and pulse became very rapid and he perspired profusely.

Treatment and Course.—Our treatment was based on (1) securing rest, sleep and food; (2) postponement of active interference with the wound until tetanic symptoms should disappear, and (3) administration of antitetanic serum.

Thus the first order ran as follows:

Patient to have any food he can handle or cares for, liquid or semisolid. Morphin sulphate, 0.01 gm., after meals and every four hours for three doses.

Chloral hydrate was prescribed the same day, 0.6 gm. every four hours; and at the end of the same day morphin sulphate, 0.008 gm., and chloral hydrate, 0.6 gm., became routine every four hours. The teeth were open 0.75 cm. and the gag reflex was kept under control by the sedatives. Chloral is a particularly valuable antispasmodic in these cases of tetanus. The muscular contractions are responsible for so great a metabolism that the efficacy of a rectal drip or rectal feedings is negligible. The only way to prevent fatal exhaustion of a moribund patient is to maintain nutrition. This can be done by securing sufficiently long intervals of remission from spasms, so that the patient is able to swallow or at least will not reject the food. In the first fifteen hours, this boy had 19,500 units of tetanus antitoxin intravenously and considerable nourishment. At times and simultaneously with the injections of serum, he often had relief from chloroform inhalation, under which he was kept as long as an hour. Night and day every four hours, first 5,000 and later 10,000 units of antitoxin were administered almost entirely by the vein. In seven days he received 172,000 units intravenously. Once we gave him a special intraspinal dose combined with an intramuscular one in addition. For five days he made no obvious improvement, but became no worse and was at times easy. The gratifying feature was that the trismus still remained incomplete.

There should be an explanation of the large doses of antiserum used in the treatment of the case under question, the continued doses of chloral and morphin, and the route selected for the administration of the serum.

Improvement was noticed first on the ninth day. The temperature was normal on the tenth day. There were no symptoms on the twenty-fifth day except local signs of a mildly suppurating wound which was, considerably later, curetted.

Treatment was confined to (1) rest, quiet, nourishment obtained by intradermal injections of morphin at four hour intervals, with chloral by mouth at the same intervals and chloroform when indications required it, and (2) intravenous injections of antitetanic serum up to 10,000 U. S. A. units, at four hour intervals. The main symptoms were universal tetanic spasms, intense reflex sensibility, and incomplete but severe trismus. There was no surgical interference with the wound while tetanic symptoms remained.

COMMENT

MacConkey[2] says:

> If we compare the mortality of all the cases treated with serum with that of the cases treated without, we must allow that the use of the serum brings little if any advantage. But if we compare the mortality of the cases treated with large amounts of serum with the mortality of the case treated with small amounts, then the beneficial results following such use of serum become manifest.

---

[1] Tetanus Lighted up by Operation, Brit. M. J. 1:883 (June 30) 1917.

[2] MacConkey, A.: Brit. M. J. 2:609 (Oct. 10) 1914.

In his article he gives the figures of 51 and 70.2 per cent. as the recovery under the treatment with small and large doses, respectively. In addition, as if thoroughly to confirm, he mentions Van der Bogert's quotation of Strock (1907), who treated his cases of tetanus during six years with small doses of serum and had a mortality of 100 per cent. Then he treated five cases with very large doses, and the mortality was 20 per cent.

What are large and what are small doses? Strock used in the individual treatment of his cases from 150,000 to 587,000 U. S. A. units. When we consider that a prophylactic dose is considered effective with from 500 such units in mild cases to 1,500 units in severe cases, we get an idea how great are to be the doses employed in the therapy of the disease. In the early stages of the war in England, we were satisfied with using a total of some 60,000 units, but I have no doubt in my mind that we used by far too small and too infrequent amounts.

Often one is accustomed to compare the use and dosage of antidiphtheritic serum with antitetanic serum; but owing to the peculiarly fixed way in which tetanic toxin combines with its chemotactic allies in the nervous system, one may only justly compare the state of *Bacillus tetani* with that stage of diphtheria which causes diphtheritic palsy.

We gave our antitoxin almost entirely intravenously. I am sure that if we had attempted to give our large doses of serum intraspinally six times a day, either we should have so stimulated the already critically sensitive reflexes to a point of the utmost danger or we should have had to endanger the patient's life with repeated administration of chloroform or ether. Our patient reacted well to the antitoxin given in this way. He developed during the first two injections some urticaria and irritation of the skin, showing a mild form of serum sickness, and once later he became a little cyanosed and dyspneic.

I am not convinced that the intrathecal route is the wisest in all cases. For rapidity of action I believe it is not so quick as the intravenous route. Intravenous anesthesia is no whit tardier than spinal anesthesia, and such anesthesia acts through the central nerve cells. The vascular system is more deliberate and more uniform in its distribution than the casual administration of a fluid into the spinal theca. We tried once an intrathecal injection of the antitoxin, and subsequently the patient had more distress in the way of elevated temperature, more rapid respirations, and spasms than by any of the intravenous injections.

Vaccination by the Spaniards.—The news item recently published in The Journal in regard to the enforcement of vaccination in Madrid, renders interesting the centennial, Feb. 12, 1919, of the death of the Spanish physician, Dr. F. Balmis, who was sent by the king of Spain, by royal order, dated June 3, 1803, to vaccinate the natives of the Spanish possessions in America. The official report of this "sanitary crusade" to New Spain was published in 1806. Stops were at the Canaries, Porto Rico, Caracas and Vera Cruz, and headquarters were established at the capital of Mexico. Balmis also organized a vaccination service for the Philippines. An account of his trip in the *Siglo Medico* states that he succeeded in taking fresh vaccine to Macao and Canton, which the British had never succeeded in doing as the vaccine brought from England had always proved inert. At St. Helena he found the English residents skeptical in regard to vaccination. The expedition lasted two years and nine months. Similar expeditions were sent out by Holland to its East Indian colonies and by Portugal to Brazil.

BROMIDROSIPHOBIA

RICHARD L. SUTTON, M.D.
KANSAS CITY, MO.

There exist a few small groups of nervous and mental disorders which involve the skin only secondarily, and which cannot logically be classified with the true neurodermatoses. Despite this fact, it is on the dermatologist that the responsibility of their clinical recognition largely rests. The more common of these affections, such as trichotillomania[1] and trichokryptomania belong in the category of "tics," or habit spasms. Next in frequency of occurrence are some of the various fear psychoses, which are characterized by a morbid dread of parasitic contamination, and of which acarophobia[2] and syphilophobia are typical examples. By patient and careful questioning, one can occasionally uncover the basis on which a fear of this kind rests, and, if the patient is sufficiently intelligent, the possibility of infection ever having taken place can be explained away. I once encountered such an instance in the case of a young woman who for more than three years had suffered from a severe traumatic dermatitis of the hands. The patient, who appeared mentally normal, had had an unfortunate matrimonial experience, and been granted a divorce from her husband about two and one-half years before she came under my professional care. Her mother told me that twenty or more times each day the younger woman would go quietly to the bathroom and thoroughly wash and scrub her hands with soap and water and a small brush, afterward applying an antiseptic, such as alcohol or compound solution of cresol. Naturally, the various local remedies prescribed for the dermatitis gave very little relief. After the patient's confidence had been gained, she confessed that her previous husband had contracted a gonorrheal urethritis about nine months prior to the time of their separation, and it was through fear of infection that she was constantly bathing and scrubbing her hands. When the matter was fully explained to her by Dr. A. L. Skoog, to whom I referred her for treatment, and she was convinced that there was no possibility of her becoming contaminated by this route, she discontinued the frequent scrubbing, and the dermatitis promptly disappeared.

Stokes[3] has reported a series of somewhat similar cases. Recently, I encountered a phobia of a different type, the fear being directed against an odor instead of an organism:

History.—A fairly intelligent man of 63, a retired farmer, had had the trouble about fourteen months. Eighteen months prior to the date of my first examination, he had developed an itchy disorder of the trunk. This affection had persisted for a fortnight or longer, but finally disappeared, leaving no trace. A few weeks later, the presence of the troublesome odor first became apparent. The trunk and axillae were primarily involved, but the area from which the "disagreeable emanation," as the patient rather grandiloquently called it, arose, gradually passed downward, and for the last twelve months had been confined to the feet and ankles.

He described the odor as of variable character. At the outset, it resembled that of "rotten onions," but at the time of the first consultation he thought his feet smelled as if he had not washed them for many months, although, he assured me, they had been bathed twice on that very day. He said that as a result of the constant and disagreeable odor, his friends had practically deserted him, and his children (he is a widower) did not care to have him come to their homes.

[3] Stokes, J. H.: Tr. Sect. Dermat. A. M. A. 1918, p. 214.

Examination.—The skin on all parts of the body was found to be normal for that of a man of 60. The soles were pink, soft and moist, and there was no exfoliation or maceration of the epidermis in the interdigital areas. There was no evidence of hyperhidrosis. The patient's shoes, which had been worn for several weeks, were no more odorous than those of an ordinary individual.

On the several different occasions that I have had opportunity to examine the patient, at no time have the extremities exhibited any unusual or particularly disagreeable odor. Despite this fact, the patient always insists that the odor is present, and that the condition is gradually growing worse instead of better.

The olfactory organs apparently are normal, and the commoner odors are recognized with ease and certainty, and without exaggeration. On matters other than the one here discussed, the patient converses intelligently and well, considering the fact that he is a man of limited education.

COMMENT

It may be that further investigation will reveal the factor underlying the psychosis in this particular case, but up to the present we have been unable to secure any tangible evidence to aid in the solution of the problem.

TREATMENT OF PNEUMONIA

GEORGE DOUGLAS HEAD, B.S., M.D. (Minneapolis)
Major, M. C., U. S. Army; Chief of Medical Service, Base Hospital
CAMP WHEELER, MACON, GA.

An epidemic of pneumonia began at Camp Wheeler about Oct. 5, 1918, and continued through the months of October, November, December and part of January, 1919. It appeared coincidently with an epidemic of influenza which swept through the camp at that time.

As two radically different methods of management were employed in the treatment of these pneumonias during this epidemic, a study of the results offers a fruitful field of observation and some helpful suggestions. It offers an opportunity to make a fair comparison between the so-called open air or open ward treatment (Group 1), in which the patient is kept practically in the open air, and the close ward management (Group 2), in which the patients are kept in warm, comfortable surroundings, well protected from cold and chilling, from currents of cold air sweeping over them through open corridors and doors, and from bathing, changing bed linen, caring for excretions, etc., in cold, chilly rooms.

The comparison between these two methods is fair because: First, the epidemic was continuous during the time this study was made. Second, the same disease, namely, influenza, and no other, was prevalent and acted as the underlying causal factor. Third, the same type of pneumonia, pathologically, was about equally distributed through the two groups; in Group 1, namely, those men treated from Oct. 5, to Nov. 24, 1918, the necropsy records showed 51.3 per cent. of lobular, 42.3 per cent. of lobar, and 6.3 per cent. of acute interstitial pneumonia; in Group 2, namely, those treated from Nov. 24, 1918, to Feb. 1, 1919, the postmortem records showed 33.3 per cent. of lobular, 60 per cent. of lobar, and 6 + per cent. of acute interstitial pneumonia. Fourth, a study of the bacteria present in the sputum and at necropsy in the fatal cases of the two groups revealed like organisms, differing only in small percentages in each group, with no predominance of virulent organisms in the group showing the highest mortality. Fifth, the number of cases observed in each group was large enough to correct any erroneous conclusions which might be drawn from the study of a small number of cases; in Group 1 (open ward group) 966 active cases, and in Group 2 (closed ward group) 435 active cases were observed. Sixth, the question of specific medication or special form of medical treatment did not operate as an important disturbing factor. There were minor differences in the management of the two groups of cases relative to the use of cardiac stimulants, sedatives, fluid intake, diet, specific serum medication, use of vaccines, etc., but these differences were not important and probably had little if any effect on the number of deaths in either group.

The method of management from Oct. 5, to Nov. 24, 1918, was the so-called open air or open ward treatment. It can be thus summarized:

1. All windows and doors in the wards were to be kept open day and night. Rain, cold winds and damp night air were no contradiction to the order.
2. No screens nor blankets were to be hung up at the windows or placed before the doors to prevent the free circulation of air in the wards.
3. Soldiers in the wards were encouraged to keep their heads close to the windows and lie so that the cold air sweeping in from the outside could be better breathed in. If a soldier complained of a cold draft of air on his head, he was told it was good for him; that the fresh air would make him well.
4. No cotton jackets or chest protectors were to be used. The patients were to be well supplied with blankets.
5. Ward fires were to be allowed to go out at night. On cold, damp days the wards were always cold and chilly, because all windows and doors were open. Under the open ward or open air treatment (Group 1) 966 patients with acute pneumonia were cared for between Oct. 5 and Nov. 24, 1918, with 135 deaths, a mortality of 13.9 per cent. November 24, while the epidemic was at its height, a radical change in treatment was made, as follows:

1. All windows and doors in the wards were ordered closed and patients guarded in every way possible from drafts of cold air, chilling and exposure.
2. All sick soldiers with pneumonia on outside porches were ordered moved into wards and cared for indoors where they were warm and comfortable.
3. Every soldier with pneumonia was provided with a cotton jacket to keep the chest warm and to protect it from drafts and currents of cold air.
4. Ward surgeons, nurses and corps boys were instructed to handle and care for their patients so as to avoid, at all costs, chilling. The bedclothing was to be kept tucked in. The arms were to be kept under the bed covers. Plenty of blankets were to be used on cold nights, etc.
5. Fires in wards were ordered kept going day and night. Wards were to be kept free from a feeling of chill in the air. This could not always be done on cold days.
6. Special nurses were provided for the desperately sick.
7. Bathing was discouraged except for purposes of cleanliness, and then only when wards were warm.

8. Attending medical officers were cautioned to avoid prolonged examinations and protect the patients well from chilling while examinations were being made.

Under the closed ward treatment (Group 2) as outlined in the foregoing, 435 patients with active pneumonia were cared for between Nov. 24, 1918, and Feb. 1, 1919, with fourteen deaths, a mortality of 3.2 per cent.

The question at once arises, Is the lowered mortality here shown in favor of the closed ward treatment a real gain in the management of the disease over the open ward method, or are the favorable results only a coincidence, an expression of a lowered mortality arising naturally in the latter part of the epidemic? It has been stated by Abrahams, Hallows and French[1] that the mortality is higher and the disease more severe in the early part of epidemics of influenza complicated by pneumonia. To quote from these authors: "It is when the epidemic is in its earlier days that it is apt to spread like wildfire and cause the greatest damage and the highest death rate."

The knowledge that we possess relative to the lowered vital force created in the tissues of the body when those structures are subjected to chilling, and a consideration of the lowered cell resistance against invading organisms created by exposure to currents of cold air, make it unreasonable to accept the open ward treatment of pneumonia as the best form of management. Any clinician who has walked through long wards of soldiers desperately sick with pneumonia, every man lying with his head and chest next to an open window through which, on cold days and nights, cold and often damp winds are blowing, who has seen these men with pinched, blue faces and cold hands and feet and has heard them again and again request that the windows and doors be closed to keep them from feeling chilly, cannot help but be convinced that this form of management for sick patients with an acute disease like pneumonia is unwise.

These patients must be kept warm and comfortable. Their skins must be red; not blue. They must feel warm; not cold. They must be cared for so as to be in a high state of febrile reaction with a high, full, bounding pulse. Heat, not cold and chilling, produces this effect.

The study of these 1,400 cases of pneumonia showing the low death rate in the Group 2 cases justifies this conclusion and points the way to the more successful management of this disease.

CONCLUSIONS

1. The epidemic of pneumonia coincident with influenza at Camp Wheeler showed a mortality of 13.9 per cent. in 996 patients (Group 1) treated by the open ward, cold air method.

2. The epidemic of pneumonia coincident with influenza at Camp Wheeler showed a mortality of 3.2 per cent. in 435 patients (Group 2) treated by the closed ward, no-chilling method.

3. While a diminished virulence of organisms or a higher resistance of soldiers may in part explain the lowered mortality in Group 2 (closed ward group), the difference in the mortality rate between the two groups is so pronounced that it seems reasonable to conclude that the no-chilling form of management employed in treating the Group 2 patients assisted in decreasing the mortality.

4. The evidence here presented warrants the more general employment by the profession of the closed ward, no-chilling management of pneumonia complicating influenza.

HEMOTHORAX FOLLOWING GUNSHOT INJURIES OF THE CHEST *

WILLIAM A. McGUIRE, M.D. (CHICAGO)
Lieutenant, M. C., U. S. Army
VICHY (ALLIER) FRANCE

Since hemothorax is one of the most frequent complications of chest injuries, it would probably facilitate our understanding of this condition if we review first the causes and sequence of events leading up to this serious complication.

Available statistics on gunshot wounds of the chest are indeed interesting and enlightening, especially when one compares the mortality statistics of this war with previous ones. Prior to the Civil War, accurate statistics were unavailable, but we are led to believe that chest wounds were invariably fatal. In the Civil War the death rate from chest wounds was 62 per cent.; in the Crimean War, 90 per cent.; in the Spanish-American War, 27 per cent., and in the present war available statistics show a wide variation, some investigators placing the mortality rate at 10 per cent., while others place it as high as 20 per cent. These conflicting figures are easily understood, and an accurate estimation cannot be obtained until a later date.

It would be natural to expect that the mortality rate of chest wounds should progressively drop with each succeeding war on the commonly accepted supposition that this mortality rate depends on the humaneness of the rifle bullet, and that this humaneness is due to the decreased sectional area and the increased velocity of the modern rifle projectile. However, this apparently beneficent advantage has been more than neutralized by the introduction of the high-explosive shell and the peculiar character of the present warfare, which necessitates a greater exposure of the upper part of the body.

Wounds of the chest comprise more than 2 per cent. of all casualties, and more than one half of these are due to rifle and machine-gun bullets. Deaths may be divided in the following percentages according to the location at which they occur:

1. *Battlefield.* One enemy investigator who examined 300 dead on the field found that 112 had fatal gunshot injuries of the thorax.

2. *Casualty clearing station and evacuation hospitals.* These show a mortality rate as high as 40 per cent.

3. *Base hospitals.* Here the death rate according to some authorities averages 8 per cent., while according to others it is 4 per cent. Soltau's records show a mortality of 27 per cent. of all chest cases reaching a medical unit.

The causes of death are twofold: anatomic and septic. Anatomic causes comprise the greater proportion, and these are the deaths occurring on the field or shortly after first medical aid is received. These anatomic causes are: (*a*) hemorrhage due to injury of the large vessels; (*b*) double pneumothorax; (*c*) shock; (*d*) edema of the lung with asphyxia, and (*e*) complicating injuries of other parts. Sepsis is responsible for a number of deaths at the evacuation hospitals, and according to Soltau the following organisms are responsible for 9 per cent. of the deaths: gas-producing organisms, 48 per cent.; streptococci, 40 per cent., and lung organisms, 12 per cent.

---

* Owing to lack of space, this article is abbreviated in THE JOURNAL by the omission of several tabulated case reports. The complete article appears in the author's reprints.

CASE OF HEMOTHORAX

S. C., Pvt. Co. C, 151st Machine Gun Battalion
Date injured, Oct. 30, 1918

Description of Wound	Wound of entrance, left chest, fifth interspace, midaxillary line; shrapnel; foreign body still present
Immediate Symptoms	Was in sitting position when struck; walked 600 yards to dressing station; marked shortness of breath; no expectoration of blood
Operation	Simple dressing
Physical Findings	Right side normal. Right border heart at midsternum. Apex fifth interspace, 1 cm. inside of midclavicular line. Slight reduplication second sound. Heart apparently rotated backward to the right. Left chest: no evidence of diaphragmatic motion on left side but right lung covers heart during inspirations;dulness begins in third interspace. Fluid below. No sign of compression above. Marked curvature of spine conveyed to the right. Dulness on left side below eighth dorsal spine. No Grocco sign. In dull area lost breath sounds, diminished vocal fremitus. Absent tactical fremitus. Small amount fluid
Roentgen Findings	The heart is slightly displaced to the right. The left chest in its inferior half casts a dense shadow which obliterates the costophrenic angle and is probably due to a hemothorax. Two metallic fragments are noted in this region. The largest one measures 1.5 cm.
Aspirations	*Not indicated*

Clinical Course				Remarks
Date	Temp.	Pulse	Resp.	
11/13	98.6	88	22	
11/14	99.0	80	20	
11/13	98.6	82	20	White blood count, 13,880; polymorphonuclears, 58 per cent.; lymphocytes, 42 per cent.
	100.0	88	20	
11/14	98.0	84	21	
	99.0	90	21	
11/15	98.4	86	20	No cough; no expectoration; slight dyspnea on mild exertion
	100.0	92	21	
11/16	98.0	84	20	
	98.8	84	20	
11/18	98.0	86	20	General condition good
	98.8	88	21	Gaining in weight
11/20	98.6	84	21	Urine normal
	98.8	86	21	Temperature always normal
11/22	98.0			
	98.6			
11/24	98.6	..	..	Evacuated to Class D. Condition good

The injuries to the thorax may be classified according to the structures involved:

1. Injuries to chest wall. Muscle laceration is always present in varying degrees, depending on whether the missile is a bullet or a shell fragment. Fracture of the ribs is, strange to say, an infrequent complication, and in seventy-five cases that I have observed, in only three were there fractured ribs.

2. Injuries to lung and pleura. Laceration of pleura and lung is always present in penetrating wounds, and the extent of the injury again depends on the character of the missile. Such injuries result in one or all of the following conditions: pneumothorax, hemothorax and lung collapse.

Unilateral pneumothorax is found most frequently in injuries due to shell fragments and to a lesser extent from rifle bullets. Double pneumothoraces, as I mentioned above, are included in the battlefield death rate.

Hemothorax is a most common finding and occurs in over 80 per cent. of chest injuries. It is a result of injury to vessels in the chest wall or is primarily due to bleeding from lacerated lung tissue.

Lung collapse of the affected lobe or contralateral lobe is an invariable result of injury, and it is probably due to Nature's attempt to control the hemorrhage from the bleeding surface. Both lung collapse and hemorrhage may occur without any perforation of the thoracic cage, and an ordinary tangential wound may be responsible for both conditions.

IMMEDIATE SYMPTOMS

On questioning over fifty patients with perforation of the lung, I elicited the following information: Those injured by rifle or machine-gun bullets experienced a light blow in the chest or back. Those sustaining shrapnel injuries experienced a heavy shocklike blow and were forcibly thrown to the ground.

Pain was the first symptom noted and was always described as only moderately severe, increasing with each respiration and referred directly to the site of the wound; but in about 10 per cent. of the cases it was referred to the shoulder, and in only one case was it referred to the upper abdomen. Most of the patients were able to walk distances varying from 100 yards to 3 miles, depending on the amount of dyspnea.

Nausea and vomiting—those precursors of shock—occurred in only 10 per cent. of the patients questioned.

Faintness in varying degrees was experienced by all, but only one became unconscious.

Dyspnea is a most constant symptom, and accompanied every penetrating chest wound, and was invariably complained of even by those suffering only tangential wounds. Here again the degree of dyspnea depended usually on the size of the missile. Machine-gun bullet injuries result in less discomfort than shrapnel wounds, which cause severe injury to the parietes with a consequent greater irritation of the pleura.

CASE OF HEMOTHORAX

C. C. S., Pvt. Co. L, 18th Infantry. Date injured, Oct. 4, 1918

Description of Wound	Gunshot wound, left chest, penetrating; wound of entrance near left axilla; *imbedded near sternum in* fifth interspace; shrapnel
Immediate Symptoms	Stricken down; crawled to shell hole; expectorated small amount of blood on second day after injury; some shortness of breath
Operation	Simple dressing; rest
Physical Findings	Respiratory excursion left side markedly decreased. Heart sounds normal. Dulness from third interspace downward. Heart: apex in fifth interspace, 2 cm. inside nipple line; breath sounds diminished anteriorly and clearly audible posteriorly; tactile and vocal fremitus diminished; probable organized clot or greatly thickened pleura
Roentgen Findings	In the region of the left costophrenic angle and extending up to the region of the fourth interspace there is a shadow of increased density which is probably the result of a thickened pleura or fluid. Left lung: its inferior half casts a dense shadow probably due to a hemothorax
Aspiration	*October 31, negative. November 10, negative*

Clinical Course				Remarks
Date	Temp.	Pulse	Resp.	
11/ 1	101.4	100	20	
11/ 2	100.4	96	24	Moderately severe dyspnea
11/ 3	101.4	92	22	Unable to walk on account of leg injury; dyspnea on exertion; no cough
11/ 4	100.4	96	24	
11/ 5	100.4	92	20	
11/ 6	100.0	94	20	
11/ 7	99.0	92	20	
11/ 8	100.2	84	20	Fluoroscope shows dense shadow, probably blood clot. 11/11: White blood count, 7,600; polymorphonuclears, 72 per cent.; lymphocytes, 28 per cent. 12/1: Temperature normal; no respiratory distress. Negative aspirations probably due to presence of organized clot. Dyspnea lessening. Condition good. Gaining in weight. Evidence of lung expansion
11/ 9	100.0	100	24	
11/10	98.6	90	22	
11/11	99.8	100	24	
11/12	98.6	92	22	
11/13	98.8	80	20	
11/14	98.0	96	20	

Cyanosis, according to those in a position to observe, is not a marked or constant symptom.

Probably those injured so severely as to go into shock must be included in the battlefield or casualty clearing death-rate, for I have seen only three patients who were so affected.

Hemoptysis, according to most observers, occurs in 90 per cent. of the cases; and in all patients whom I have questioned, with the exception of two, I received a definite history of hemoptysis. This was one of the first symptoms and to the patient the most alarming one, especially if the accompanying dyspnea was severe.

CASE OF HEMOTHORAX

G. P., Pvt. Co. I, 309th Infantry. Date injured, Nov. 11, 1918

Description of Wound	Shrapnel wound, penetrating right scapula region near posterior axillary line; no wound of exit
Immediate Symptoms	Severe pain right upper chest; was able to walk 1 kilometer; hemoptysis immediate, lasting seven hours; cough since then continuous with occasional blood-streaked sputum
Operation	Débridement of wound; thorax not opened
Roentgen Findings	The heart is slightly displaced to left side. Right lung shows evidence of a metallic fragment 2.5 cm. by 1.25 cm., lying on the level of the eighth rib about 3 cm. to the right of the median line surrounded by an area of increased density, which extends to the axillary line and which is probably due to the presence of hemothorax. There is evidence of a fracture of the sixth rib on its posterior aspect. Surrounding the fragment is a shadow of lesser density which may be due to the presence of suppurative focus
Physical Findings	Respiratory excursion equal on both sides. Heart: apex beat, fifth interspace; left border in nipple line. Left chest normal; dulness from midaxillary line posteriorly right side and from sixth dorsal downward; tactile and vocal fremitus diminished; whispered voice not heard posteriorly
Aspiration	Not indicated; no cardiac or respiratory embarrassment; temperature normal

Clinical Course				Remarks
Date	Temp.	Pulse	Resp.	
11/13	98.6	88	26	White blood count, 18,840; polymorphonuclears, 60 per cent.; lymphocytes, 40 per cent.
	98.6			
11/14	98.4	88	24	
	98.6	89		Slight cough increased on mild exertion
11/16	98.0	86	22	
	98.4			Expectoration moderate in amount; never blood-tinged
11/17	98.6	84	20	
	98.8			
11/18	98.6	86	21	Slight shortness of breath after mild exertion
11/20	98.6	84	21	
11/22	98.8	82	20	General condition good; appetite good, increasing in weight
11/24	98.6	80	20	Urine normal Temperature normal every day. Evacuated to Class D November 24; condition good; no change in physical findings

The amount of blood expectorated varied from blood-tinged sputum to mouthfuls of blood, and in every case in my series the hemoptysis lasted not longer than four days, probably until the injured lung had collapsed and effected hemostasis.

As regards treatment, I will confine myself strictly to cases I have observed; consequently a discourse on this all-important question will necessarily be as brief as the treatment accorded these particular patients. The records show that of twenty-five cases, twenty-two were surgically treated by simple débridement of the wound of entrance, with removal of the foreign body if readily accessible. Three cases were subjected to radical open operations in which the lung was exposed, the foreign body removed, the blood clot evacuated, and the pleura muscles, etc., closed in layers. Of these three cases, two developed signs of infected fluid from seven to ten days later, and resection with drainage was performed. The remaining patient made an uneventful recovery, and examination two weeks after operation showed only a small amount of blood in the costophrenic angle, with slight collapse of the lower lobe.

All gunshot wounds of the chest were kept under observation and treatment at the evacuating hospitals for not less than ten days, so that all cases coming under my observation at the base hospital were more than two weeks old, the average length of stay in the evacuation hospital being sixteen days.

TWO GROUPS OF CASES: STERILE AND INFECTED

Routine examination and several days' observation of these twenty-five cases made it possible to divide them readily into two groups:

Group 1 is made up of those cases, eleven in number, in which patients had suffered perforating machine-gun bullet wounds or less severe tangential wounds, and who had no symptoms with the exception of slight dyspnea on exertion and practically negative physical and roentgenographic findings.

Group 2, comprising also eleven in number, consists of those patients who had suspicious symptoms and definite physical findings both clinical and roentgenographic.

Those belonging to the first group were evacuated in two or three weeks. The second group comprised the hemothoraces.

Hemothorax occurs in 80 per cent. of gunshot wounds of the chest, and is due to hemorrhage into the pleural cavity from lacerated lung tissue and occasionally from injured intercostal vessels. It is usually observed on the third day after injury, and appears about the time that hemoptysis ceases. As for the symptoms resulting from this collection of blood, pain was practically negligible a few weeks following the injury, and complaint was made of only slight discomfort. Dyspnea depended on the extent of lung collapse and the amount of fluid present. While lying quietly no dyspnea was experienced in any of the aseptic cases I observed, but slight exertion, such as getting out of bed or walking a few steps, caused some distress. Cough and expectoration were very slight in cases of sterile hemothorax. Six sterile cases showed an average evening temperature of 99.4 over a period of ten days. This temperature was regular and constant and not variable as in the infected type. The pulse was usually accelerated, but not markedly. Respirations were slightly increased, ranging from 19 to 23, with slightly decreased excursion on the affected side. Gastro-intestinal disturbances were not present in any cases observed.

CASE OF HEMOTHORAX

E. E. D., Sgt. Co. A., 7th Engineers. Date injured, Sept. 31, 1918

Description of Wound	Machine-gun bullet, left chest, opposite fourth dorsal spine, exit second interspace, to left of midclavicular line. November 14: posterior wound healed; anterior wound almost healed
Immediate Symptoms	Pain left chest and shoulder; no hemoptysis, at present some shortage of breath, slight; was able to walk 300 yards to dressing station
Operation	Simple dressing; rest
Roentgen Findings	Left lung: in its inferior half casts a dense shadow, probably due to presence of fluid. The costophrenic angle is obliterated. Fluoroscopy shows density "2"; limiting level noted on sitting posture
Physical Findings	Right lung normal; right border of heart at right sternum; left border at midclavicle line. Heart sounds normal; left side is bulging, and moves very slightly. Interspaces in left side full; dulness seventh interspace, midaxillary line; normal lung above; fluid below; posterior dulness to seventh dorsal spine; all signs of fluid, and slight Grocco
Aspiration	Negative

Clinical Course				Remarks
Date	Temp.	Pulse	Resp.	
11/14	98.0	88	20	White blood count, 11,120; polymorphonuclears, 70 per cent.; lymphocytes, 30 per cent.
11/22	98.6	84	20	
11/23	98.6	84	20	Slight dyspnea on mild exertion; no cough; no expectoration; appetite excellent; gaining in weight; urine normal
11/24	98.6	84	20	Evacuated to Class D. Temperature always normal. Condition excellent. Probably an organized blood clot left lower chest

The physical findings presented by these aseptic cases were thus recorded: As to general appearance, there was slight pallor, but no evidence of pronounced septic absorption. Respiratory excursion on the affected side was changed, and some retraction was present. There was deficient diaphragmatic movement on the affected side. The heart was displaced, the condition depending on the amount of fluid. Palpation showed the limited excursion and noted the decreased tactile fremitus. Percussion revealed flatness, but change in position of the patient did not always result in shifting of the area of dulness, owing probably to the different stages of organization of the blood clot and its comparative fixation in the pleural cavity. Auscultation gave conflicting and misleading information. As a rule, breath and voice sounds were diminished or lost, but sometimes, even in the presence of a large amount of fluid, all the signs of pulmonic consolidation may be present. This may be explained by the very frequent accompanying collapse of the lung, the presence of adhesions, and the varying stages of coagulation of the blood. Leukocyte counts in the aseptic cases averaged 11,000, with 72 per cent. polymorphonuclear leukocytes.

CASE OF HEMOTHORAX

R. E., Pvt. Co. E, 355th Infantry. Date injured, Nov. 4, 1918

Description of Wound	Gunshot wound, left chest, 5 by 3 inches; slight suppuration; shrapnel; nonpenetrating; entrance in postaxillary *line in sixth interspace*
Immediate Symptoms	Walked about 50 yards and then fainted; marked shortness of breath; some expectoration of blood
Operation	Débridement of external wound; foreign body removed from deep muscles of back
Physical Findings	Heart: apex beat fifth insterspace one half inch inside nipple line; heart sounds normal; respiratory excursion left side, right side normal; left chest area of hyperresonance in fourth and fifth interspaces in anterior axillary line; dulness posteriorly; tactile fremitus decreased; vocal fremitus normal; breath sounds slightly decreased posteriorly
Roentgen Findings	The heart is somewhat enlarged; left lung casts a dense shadow of increased density which may be due to the presence of a thickened pleura or fluid
Aspiration	Not indicated

Clinical Course				Remarks
Date	Temp.	Pulse	Resp.	
11/12	98.6	78	21	White blood count, 11,280; polymorphonuclears, 78 per cent.; lymphocytes, 22 per cent.
11/13	98.6	72	20	
11/14	98.8	70	20	
11/15	98.6	70	20	No cough; no dyspnea; general condition excellent
11/18	98.0	72	20	Wounds healing satisfactorily
11/19	98.4	72	21	Urine normal
11/22	*98.6*	*80*	21	*Temperature always normal*
11/24	98.6	..	..	Evacuated to Class D; condition excellent

All these cases were subjected to aspiration and studied fluoroscopically, but I wish to include these observations under differential diagnosis between the sterile hemothorax and the infected hemothorax.

Referring again to the twenty-five recorded cases, I wish to recall that three were draining empyemas when they reached the base hosital center. Two cases belonged to Group 1, having no symptoms and comparatively no physical findings. Group 2 comprised the hemothoraces, and of these six were aseptic cases, leaving five for the infected type.

Symptomatically, these infected cases differed thus from the sterile cases: Pain was very severe, whereas in the aseptic type it is negligible. Dyspnea was very marked, the distress being striking even with the patient lying quietly. Cough and expectoration were moderate in amount, usually occurring at night. The temperature usually ranged from 100 to 103, with very irregular excursions, whereas the temperature in the sterile cases was uniform from day to day until normal was reached. The pulse was rapid in all cases, varying from 110 to 120, and was somewhat irregular. Respiration increased, and ranged from 24 to 28. The gastro-intestinal disturbances that usually accompany any septic absorption were present. Among nervous manifestations, sleeplessness was rather characteristic.

The physical findings differentiating the two conditions may be thus described: In the general appearance, pallor was marked; cyanosis of the lips was noticeable; also an anxious expression and rapid loss of weight were all striking. The chest was practically immobile, with no diaphragmatic excursion, while the interspaces were bulging. In one case a definite pulsating upper chest was noted simulating a pulsating area. Heart displacement rapidly increased. In one case the cardiac impulse was best seen in the sixth right interspace beyond the nipple line. Gallop rhythm was also noticed in one case, and this disappeared after the evacuation of 1,700 c.c. of fluid. By palpation, in addition to noting the decreased tactile fremitus and excursion, we also found increased tenderness and hyperesthesia of the skin on the affected side. Percussion gave a cracked note resonance in most cases, and was due to the presence of air generated by the infecting organisms. Auscultation revealed the conditions previously noted in the sterile cases, and in addition we also heard splashing and gurgling characteristic of the mixing of air and fluid. The leukocyte count in these infected cases averaged 16,000, with 80 per cent. polymorphonuclears.

CASE OF HEMOTHORAX

A. I., Pvt. Co. A, 9th Infantry. Date injured, Nov. 4, 1918

Description of Wound	Machine-gun bullet; wound of entrance, neck, left side, posterior border of *sternocleidomastoid* muscle; exit, fourth interspace, right midaxillary line
Immediate Symptoms	Severe pain right chest and neck; unable to rise; very slight shortness of breath; slightly blood-tinged sputum *for two days after injury*
Operation	*November 5, aspiration 300 c.c.;* blood culture negative
Physical Findings	Heart: apex beat fifth interspace inside nipple line; heart sounds normal; respiratory excursion *markedly* decreased right chest; diaphragmatic excursion barely perceptible; left chest normal; impaired resonance right upper lobe down to third rib; dulness from fourth rib in nipple line downward *and backward; tactile and* vocal fremitus present; breath sounds decreased; friction rub over middle and lower lobes in midaxillary line and posteriorly; slight Grocco sign; slight compression of right lung; *probably small clot in pleura*
Roentgen Findings	Right chest, small metallic fragment on level of sixth rib; costophrenic angle obliterated, probably owing to presence of fluid; fracture second rib posterior *aspect near median line*
Aspiration	Not indicated

Clinical Course				Remarks
Date	Temp.	Pulse	Resp.	
11/25	98.0	72	20	White blood count, 13,200; polymorphonuclears, 67 per cent.; lymphocytes, 33 per cent. Temperature normal. Severe pain right upper *arm, inner* side; *nerve* of Risberg. Very slight dyspnea on exertion. Pain in right upper arm subsiding. Appetite good. Condition good. Gaining in weight. Evidence of increasing lung expansion. Fluid probably resorbing
11/26	98.6	70	19	
11/27	98.6	72	20	
11/28	98.4	70	19	
11/29	98.6	64	19	
12/ 1	98.4	70	18	
12/ 2	98.6	80	20	
12/ 3	98.4	82	20	
12/ 4	98.4	72	19	
12/ 6	98.0	70	20	

This wide variance in symptomatology between the aseptic and the septic cases is not always so *striking* and conclusive, many of the cases being borderline problems which require closer study and the application of instruments of precision afforded us by the laboratory and the roentgenologist.

TYPES OF FLUID AS SHOWN BY ASPIRATION

A differential diagnosis is never complete without determining the character of the fluid by aspiration.

In all eleven cases in both groups exhibiting evidences of fluid, aspiration was done. Gross examination of the aspirated fluid gives reliable diagnostic information, and three distinct types of fluid were noted.

CASE OF HEMOTHORAX

E. H., Pvt. Co. F, 102d Infantry. Date injured, Oct. 28, 1918

Description of Wound	Shrapnel perforating left upper chest; wound of entrance in second interspace at middle third of left clavicle; exit opposite fourth and fifth dorsal vertebra; sucking wound
Immediate Symptoms	Did not fall to ground; walked 20 feet and sat down on account of weakness and dizziness; had no dyspnea; did not expectorate blood
Operation	Débridement of muscles of back; suture of big muscles to close sucking wound
Roentgen Findings	Evidence of foreign body, 10 by 7 mm., on level of eighth dorsal vertebra, 4 cm. to the right at median line; left chest casts a dense shadow, probably due to hemothorax; heart markedly displaced to right side. Fluoroscopic examination shows pulsating right heart in right axillary region; fluid, large amount left chest
Physical Findings	Left chest bulging; interspaces bulging; no excursion of left chest; no diaphragmatic movement; heart impulse in fifth interspace in right nipple line; right border of heart beyond right nipple line; tactile and vocal fremitus lost, left chest; dulness up to second interspace, anteriorly and posteriorly; no breath or voice sounds audible
Aspirations	November 29, 700 c.c. port-wine colored fluid; smear shows many polymorphonuclears and gram-positive bacilli and diplococci in chains. December 2, 3,000 c.c. chocolate-colored fluid; polymorphonuclears, 10 per cent.; lymphocytes, 60 per cent.

Clinical Course				Remarks
Date	Temp.	Pulse	Resp.	
11/28	99.0			
	100.4	98	24	
11/29	99.0	98	24	White blood count, 10,520; polymorphonuclears, 78 per cent.; lymphocytes, 22 per cent. Dyspnea marked. Sleeplessness. Marked pallor Loss of weight marked
	101.0	106	26	
11/30	100.0	100	26	Operation; rib resection; 100 c.c. chocolate-colored fluid
	101.6	112	28	
11/31	100.0	98	26	
	102.0	102	29	
12/ 2	99.0	100	30	
	103.0	116	28	
12/ 3	99.0	100	26	Heart now approaches right border of sternum
	101.6	114	28	
12/ 4	100.0	98	26	
	102.0	112	30	
12/ 5	99.0	100	28	Dyspnea relieved; draining freely
	101.6	116	28

	101.0	100	26	
12/ 7	98.8	90	24	Appetite good
	99.8	98	24	
12/ 8	99.0	92	24	Gaining in weight
	99.0	94		
12/10	99.0	80	20	Heart in normal position
12/11	98.6	90	20	Discharge lessening
	99.4	96	22	
12/14	98.8	90	20	Evidence of some lung expansion
12/16	98.6	86	20	
	98.8	86	20	
12/18	98.8	84	20	

Type 1.—A clear, thin, pinkish red, slowly coagulating fluid was found in four of the sterile cases. The slow coagulation time and the color of the fluid are probably due to the interference with clotting by the respiratory movements, which throw out the fibrin and cause the serum to retain the red cells. Microscopically, disintegrating red cells and occasional polymorphonuclears were found and no bacteria.

Type 2.—A rather dark, somewhat cloudy red fluid resembling port wine was found. Cellular examination showed many polymorphonuclears, lymphocytes and red cells in various stages of disintegration. This type of fluid was found in two cases in which subsequently drainage was done, so it is to be regarded as extremely suspicious even though the culture is negative.

Type 3.—A thick, chocolate-colored fluid was found in three cases at first aspiration, and also found in the two cases above mentioned on subsequent aspiration. The cellular examination in these cases showed a high percentage of polymorphonuclears, and the culture in every case showed gram-positive bacilli and diplococci.

VALUE OF THE FLUOROSCOPE

In conjunction with aspiration I found the fluoroscope an invaluable aid. Previous to an attempted thoracentesis, every chest was observed fluoroscopically, and information on the following matters was obtained:

1. Absence of respiratory excursion on the affected side.

2. Displacement of the heart.

3. Decreased movement and sometimes complete immobility of the diaphragm, which is probably a protective reflex fixation with a temporary partial paralysis.

4. High riding diaphragmatic dome, which can also be attributed to the foregoing mechanism. This is invaluable information preceding a chest puncture, because it gives warning of the danger of a low puncture or resection with consequent injury to abdominal viscera.

5. Amount of fluid present. With the patient in the recumbent position, the disseminated fluid gives a hazy appearance to the entire side of the chest; but in the sitting posture, a moderate opacity can be defined and a limiting level noted.

CASE OF HEMOTHORAX

L. D. H., Pvt. Co. G., 322d Infantry. Date injured, Nov. 11, 1918

Description of Wound	Shrapnel wounds, multiple: (1) wound of entrance at spine of right scapula; (2) posterior aspect right shoulder; (3) seventh interspace posterior axillary line; no wounds of exit
Immediate Symptoms	Walked three miles; did not expectorate blood
Operation	November 11, simple dressing; rest. November 25, rib resection eighth posterior axillary line; 1,000 c.c., slightly offensive, thick, chocolate colored
Roentgen Findings	Fracture in the fifth rib; metallic fragment, 7 by 5 mm., just above this region; right costophrenic angle is obliterated, probably owing to fluid; a second metallic fragment, 12 by 5 mm., lies on the level of the second lumbar vertebra
Physical Findings	Heart gallop, rhythm slight, reduplication of second mitral; friction rub in second and third left interspaces, right chest; limited excursion of right chest
Aspiration	November 22, chocolate colored, 35 c.c.; culture shows large gram-positive bacilli and diplococci in chains; smear shows many bacilli and leukocytes

Clinical Course				Remarks
Date	Temp.	Pulse	Resp.

12/ 6	98.8	82	22	
	99.8	88		
12/ 8	98.0	86	22	

6. Presence of shadows. The character of the fluid, of course, cannot be determined; but one case that gave two negative aspirations showed fluoroscopically the presence of a shadow with the density of liver substance. This patient had a chill and rise of tem-

perature after each chest puncture, and ran a septic course for four days. The only explanation I can offer is readily afforded by the fluoroscope, which revealed a dense shadow that could be interpreted as a firmly organized blood clot. The symptoms were probably due to the liberation of more blood by disturbing the blood clot.

7. Presence of air, which is manifest by the appearance of eddies, whirls and bubbles. Combined with clinical signs of infection, the presence of air gives presumptive evidence of the presence of infection.

8. Localization of foreign body to determine its position with a view to removing it, if accessible.

Roentgenograms were taken in all cases, and are valuable aids in determining abscess formation, lung collapse and other complications, and are also valuable as permanent records.

BASIS FOR DIFFERENTIAL DIAGNOSIS BETWEEN ASEPTIC AND SEPTIC HEMOTHORAX

Differential diagnosis between aseptic and septic hemothorax is based on these findings:

1. The aggravation of all symptoms due to the presence of blood in the pleural cavity.
2. Increase in all the physical findings.
3. Presence of a pneumohemothorax where no air had been previously noted.
4. Gross characteristics of the aspirated fluid, the chocolate-colored fluid being diagnostic of infection.
5. Cellular examination of the aspirated fluid.
6. Positive culture of aspirated fluid.
7. Leukocytosis.

COMPLICATIONS

Two patients were suspected of having abscess of the lung. One patient presenting evidence of only a slight amount of fluid in the costophrenic angle, but with a leukocyte count of 17,000 and evidence of septic absorption, expectorated 500 c.c. of pus in twelve hours and the symptoms subsided, the white count dropping to 9,000 in four days. This patient also showed deep in the thorax a machine-gun bullet which moved up and down with the respiratory movement and laterally synchronously with cardiac action. In the other case, the initial aspiration revealed pure pus, a subsequent one chocolate-colored fluid. Two weeks after rib resection was done, a foul odor was noted in the draining empyema. A culture showed the same organism found on first aspiration. The probable explanation is that it was due to an externally rupturing lung abscess.

TREATMENT

Five of the patients proving to be of the infected type were operated on under local anesthesia, a rib resection being done and two drainage tubes introduced. Subsequent local treatment consisted in maintaining free drainage. In one case that was draining poorly a water pump suction apparatus was used and proved successful. In twenty-four hours 300 c.c. of fluid were collected.

General treatment consisted in giving large quantities of highly nutritious food. No facilities were available for determining nitrogen waste in the discharge. This nitrogen waste can be neutralized by selecting a diet rich in proteins, thereby replacing the lost nitrogen.

The main consideration in treating these cases is the restoration of normal lung function. Much can be accomplished toward this end by stimulating lung expansion through the means of blow-bottles and mild exercises. These facilitate the evacuation of pus, discourage the formation of new adhesions, and help to destroy the old ones. They also enable the collapsed lung to return, at least partially, to its former state of respiratory activity.

SUMMARY

In the present war, gunshot wounds of the chest are frequent and severe, but the advance in thoracic surgery has made possible a comparatively low mortality rate.

2. Hemothorax is the most common complication of the chest injuries.

3. An early differential diagnosis between sterile and infected hemothorax is essential.

4. A practically absolute diagnostic evidence is afforded by the gross, microscopic and cultural characteristics of the aspirated fluid.

5. Fluoroscopic examination in all cases is important.

6. Prompt drainage of these infected hemothoraces should be followed by an after-treatment that encourages the restoration of respiratory activity on the affected side.

EMPYEMA AT CAMP MILLS, L. I.

WITH SPECIAL REFERENCE TO THE USE OF THE PHILIPS EMPYEMA APPARATUS

H. B. PHILIPS, M.D. (New York)
First Lieutenant, M. C., U. S. Army

AND

A. G. LANGMANN, M.D. (New York)
First Lieutenant, M. C., U. S. Army

WITH COMMENT ON THE APPARATUS BY

C. L. MIX, M.D. (Chicago)
Major, M. C., U. S. Army; Medical Chief, Base Hospital

CAMP MILLS, GARDEN CITY, L. I., N. Y.

The successful treatment of empyema depends on the recognition of the basic pathology of the condition. In the treatment of a collection of pus elsewhere in the body, simple incision and the establishment and maintenance of adequate drainage suffices in most cases to effect a cure. But in the chest cavity a different condition exists. When the pleural sac is opened for the drainage of pus, the normal negative pressure is immediately changed to atmospheric pressure (15 pounds to the square inch), the elastic lung collapses, the respiratory and circulatory embarrassment of the patient is increased instead of lessened, and a condition results which is the very thing to be avoided. To put it in the simplest form, it is adding a complication instead of ameliorating or aiding the condition. The indications for the most successful treatment of this condition are obvious: the establishment of adequate drainage coincident with the exclusion of atmospheric pressure.

In a previous preliminary report,[1] the efficacy of a new method for the treatment of empyema, with detailed histories of three cases so treated, was indicated. A brief summary of this report, including a short description of the apparatus, forms an appropriate introduction to this paper.

---

[1] Philips, H. B.: New Method of Continuous Drainage for Empyema, Surg., Gynec. & Obst. 24: 236 (Feb.) 1917.

The apparatus consists of a special cannula, a bottle, a negative pressure manometer, a suction pump, and connecting rubber tubing. The cannula is of special design so as to be used for a trocar cannula for the thoracotomy, and being also nonobstructible, it remains in the chest wall until the empyema sac has been obliterated. A rubber suction cup surrounds the cannula, and permits of an absolutely air-tight connection with the pleural sac. This makes it possible to empty the pleural sac with nonobstructible drainage, maintaining a continuous negative pressure of from 30 to 60 mm. of mercury until the empyema sac has been obliterated and firm adhesions have formed between the visceral and parietal pleurae, when the apparatus may be removed.

The advantages anticipated and found with this method of treatment were numerous. The control over the negative pressure throughout the treatment assured against primary collapse of the lung and its coincident grave dangers. There was not the slightest suggestion of respiratory embarrassment. A means was afforded for keeping the lung expanded automatically and continuously, thus promoting early adhesions between the pleurae, and preventing the formation of a dead space. The nonobstructible cannula, which is a trocar cannula, convertible into a cannula with a hidden curet, assured ample drainage and obviated rib resection and other operative procedures. The original dressing was the only one, so that secondary infection from extraneous sources was excluded. Moreover, the mussy, obnoxious dressings with which we are all familiar were done away with, all the pus accumulating in the bottles (in one case 11 liters [quarts]). The duration of the treatment was very materially reduced and a method afforded which was sanitary, pleasing and simple.

Having thus described the features of the apparatus and what it accomplished in the first short series of cases, we shall further refer to it in describing the complete course of treatments followed in a series of about fifty cases that occurred at this post during the influenza epidemic. Mention should be made of the fact that but one apparatus was available during the height of the epidemic, and it was only at the end of the series that enough apparatus were on hand to meet the demand, so that it was necessary to resort to varied treatments, which, however, were all consistently conservative.

The plan of treatment that was followed before the apparatus arrived, and while there was but one in use, was to make repeated aspirations with aseptic technic, trying as far as was possible to exclude atmospheric air from the pleural sac during the puncture. This was repeated from time to time in all cases advisable. It was found, however, that in several of the cases the pus was so thick as to make this procedure impossible. These cases were then submitted to either intercostal drainage or rib-resection operations. In the absence of Philips' apparatus, cannulas, firsf of rubber and then of metal, were used, in an attempt to make suction through intercostal drainage and to exclude atmospheric pressure. A special adhesive paste, referred to later, was used to make the cannula air tight in the chest wall. The cannula was then connected to an air-tight stoppered bottle, and in this way it was attempted to maintain a continuous negative pressure while draining the pleura. Owing, however, either to the obstruction of the improvised cannulas or to leakage, this method was soon abandoned, and thereafter all cases which did not improve after aspirations were submitted to rib-resection operations for drainage. Finally, with the arrival of the apparatus, all remaining cases were treated solely with them, so that an unusually good opportunity is offered for a comparative study of these methods, checked up by very frequent roentgenographic examinations. It should be mentioned that neutral solution of chlorinated soda (Dakin's solution) was used as a routine for repeated and regular irrigations of those cases treated by intercostal and rib-resection drainage.

For a clear consideration of these cases, it is necessary to divide them into the following groups for study:

1. Those treated by simple repeated aspirations.
2. Those treated by intercostal drainage.
3. Those treated by rib-resection drainage.
4. Those treated with the Philips apparatus.

1. CASES TREATED BY SIMPLE REPEATED ASPIRATIONS

Simple repeated aspirations were employed as a matter of routine when consistent with the condition of the patient. The aspirations were done at three to seven day intervals, whenever the condition of the patient indicated this procedure. In the great majority of cases this method failed, and more radical treatment had to be instituted early. Of a group of seventeen cases, three terminated successfully without any treatment but repeated aspirations. In most cases, however, early symptoms of aggravated sepsis or the appearance of a pneumothorax, although persistent care was taken to prevent this complication, indicated better drainage methods. Of the three cured cases, the exudate in one was serous and in the other two it was purulent. Two of the cases terminated fatally. There was no characteristic bacteriology that permits of any inference as to the cause of the fatality; however, both patients were extremely toxic.

One must keep in mind that cures with this method of treatment are the exception and not the rule, and that the personal equation of the patient, and the exceptional pathology of the condition, make this unusual termination of the condition possible. In this group of cases it was found impossible to exclude air from the pleural sac uniformly. Even when the aspirations were thought to have been accomplished without the entrance of air into the pleura, roentgenoscopy would disclose a pneumothorax in the greater number of cases. In many cases this method was a failure from the very start, because of the thick character of the pus, which plugged the needle or cannula immediately after its insertion. The Potain aspirator was used, as were also small trocar cannulas, which were connected tightly to bottles and suction pumps in attempts to aspirate the pus and at the same time to prevent pneumothoraces. Owing to either plugging of the drainage or to leaking, these methods were soon abandoned.

Our experience has led us to feel that the contraindications for repeated aspirations are:

1. The character of the exudate such that it obstructs the cannula or needle.
2. Absence of improvement following this treatment.
3. The appearance of a complicating pneumothorax, following aspirations.
4. Severe toxemia of the patient.

empyema sac is completely obliterated. A constant feature is the remarkable ease and comfort of the patient when the drainage is started, and during the course of the application of the apparatus. This subjective well being is decidedly conspicuous by its absence in other methods of drainage. An extremely unusual subjective and objective improvement in the condition of the patient is invariably present. Cyanosis and dyspnea disappear almost from the start, and do not return. This has been nothing short of phenomenal in cases of pyopneumothorax, when it appears to pull the patient from a yawning grave within several minutes, whereas other methods of treatment aggravate the symptoms and condition, and contribute to the mortality. Checking up these cases very closely with roentgenograms has shown that the apparatus gradually expands the lung to its full capacity, and keeps it fully expanded until adhesions between the pleurae are firm and the apparatus can be removed and the cannula tract drained.

2. The necessity for operation is done away with entirely. The special cannula is constructed with a special device which enables the operator to use it first as a trocar cannula to do the thoracotomy through an intercostal space. The cannula stays in situ in the chest wall during the entire treatment, and does not have to be removed if it should become obstructed. By a slight manipulation, the original trocar blade which projected from the cannula can be changed to a curet, so that the operator is able to cleanse the cannula without removing it from the chest wall. This gives a practically nonobstructible drainage through an intercostal space, and does away with the necessity for rib resections. The insertion through the chest wall can be done absolutely painlessly, with the use of a local anesthetic. A general anesthetic is unnecessary. The apparatus has been applied repeatedly without the slightest pain or apprehension on the part of the patient.

3. Secondary infection is excluded. The cannula is fastened to the chest wall by a suction cup device, adhesive straps and gauze, with a liberal application in layers of a special adhesive paste made of common glue, 50 parts; water, 50; thymol, 2; glycerin, 2, and calcium chlorid, 2. This makes an air tight and permanent dressing which will stay absolutely clean and air tight as long as two weeks. Consequently there is no portal of infection from extraneous sources. Numerous cases have been checked up bacteriologically, and secondary infection has been found to be excluded. The value of this feature cannot be overestimated, for it has long been agreed that one of the principal factors contributing to the high mortality of empyema is secondary infection.

4. The duration both of the treatment and of the condition is very materially shortened. The exclusion of atmospheric pressure and of secondary infection precludes the formation of a large dead space, secreting endless pus. It is this condition that all surgeons and practitioners dread, for with its establishment a chronic, long drawn out condition is guaranteed. This method, applied as early as possible, can justifiably be considered an absolute prophylactic to a chronic long standing empyema, which in the end will necessitate a very radical rib-resection operation to obliterate the dead space. The average duration of the actual empyema has been less than ten days after the application of the apparatus, and when it is removed, it will leave a completely or very nearly completely expanded and adherent lung.

5. A functionating lung is obtained from the very start. More accurately as checked up by the roentgen ray, a completely or very nearly completely expanded lung is present and functionating within a few hours after the application of the apparatus, and this can be demonstrated clinically and by roentgenoscopy any time thereafter. This feature is certainly conspicuous by its absence in other methods of treatment which permit the entrance of air into the pleural space, even if but temporarily. Needless to say, the additional advantages to the patient of a functionating lung, when the opposite side has been incapacitated by a pneumonia, is tremendous, and a few patients were unquestionably saved and others very materially improved by the rapid restoration of a functionating lung. This is confirmed in a way by the experience of the roentgenologist. In making the long exposures necessary with the bedside roentgen apparatus (no intensifying screens being available), just prior to the application of the apparatus, it was necessary to make three interrupted exposures to get a negative. Roentgenograms made within three hours after the apparatus was applied were taken very easily, the patient holding his breath the necessary nine or ten seconds without any interruption.

6. A clean, sanitary, pleasing, economical and simple method is secured of getting rid of the pus. During the entire application of the apparatus, the dressings remain as perfectly clean as when originally applied. The adhesive paste interspersed between the layers of the dressings makes an ideal air-tight dressing which does not leak. The usual mussy, obnoxious dressings that are always associated with empyema cases are entirely done away with, all the pus being accumulated in the bottle, which itself is sealed air-tight. The foul odors, pussy dressings, pain and discomfort to the patient, not to dwell too forcibly on the objections of drainage operations, with the squirting and sputtering of pus all over the operating room, the acute torture and the alarm of the patient when his pleural sac is opened—these features, without exception, are all relegated to the past. One visitor, after looking over an array of six cases being treated with the apparatus, after inspecting the perfectly clean dressings (some of which had been on over a week), and the bottles at the bedsides filled or partially filled with pus, noting the ease and comfort of the patients and the absence of odors, remarked that the place looked like anything but an empyema ward. It is undoubtedly of interest to note that as much as 10 liters of pus have accumulated in the bottles of individual cases, still preserving the physical appearance just described.

Attention should be called to the fact that the apparatus can be used in ordinary serous pleural effusions, and has been used with great success. The danger of secondary infection is minimal, and the means afforded of expanding a chronically compressed and collapsed lung, by the apparatus, cannot be overlooked.

GENERAL CONCLUSIONS

1. Repeated aspiration as a curative procedure is not feasible in most cases. As a palliative procedure it permits of the formation of a pneumothorax in most cases, and its value is therefore questionable. Severe toxemia is a contraindication to repeated aspiration treatment.

2. Intercostal drainage is impossible, in our experience, without the production of a complicating pneumothorax; and as it possesses the disadvantages without the advantages afforded by rib resection, we feel that the latter is the operation of choice if the apparatus is not available.

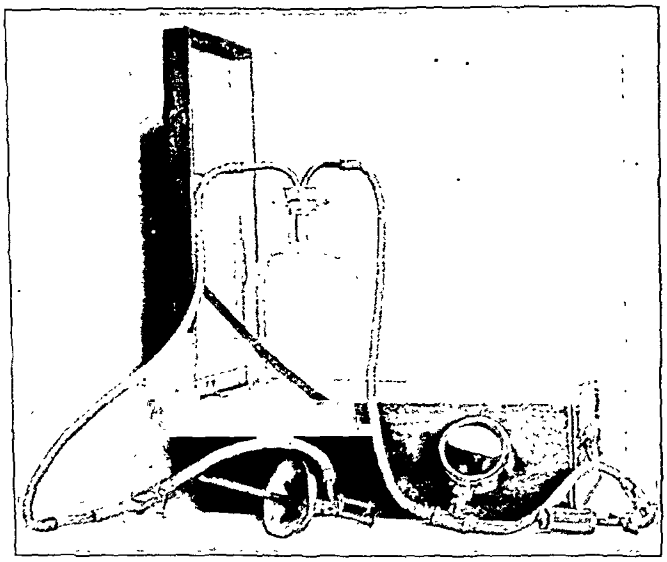
3. Shock and cardiac and respiratory embarrassment are minimized with the use of the apparatus.

4. The apparatus affords the most desirable method of treatment in any stage of the empyema because: (*a*) There is exclusion of atmospheric pressure; (*b*) secondary infection is excluded; (*c*) the necessity for operation is done away with entirely; (*d*) the duration both of the condition and the treatment are very materially shortened, and (*e*) it is a clean, simple, sanitary and economical method of getting rid of the pus.

5. Open pneumothorax is absolutely prevented by the use of the apparatus.

COMMENT ON PHILIPS' APPARATUS FOR THE TREATMENT OF EMPYEMA, BY DR. MIX

In civil practice the treatment of empyema has always been in the main simple. Intractable cases were occasionally encountered which demanded special measures, but as a rule case after case yielded to the simple operation of rib resection. The stubborn cases were usually passed along to some surgeon who instituted special measures for continuous drainage, and ultimately most patients recovered.



Completely assembled apparatus with curet projecting from cannula orifice.

In army practice, the treatment of empyema has been almost futile. *Streptococcus hemolyticus* seemed to be the active germ in most cases, and its virulence in some cantonments has been prodigious. Methods in vogue in civil practice were totally inadequate. At first, camp surgeons resected ribs as soon as an internist discovered pus, and the patient died. Then the internist began to hold back his cases from the surgeons because he found that repeated aspirations gave better results. Throughout all the struggle to succeed against empyema ravages, every one knew that the principle to be sought after was a continuous drainage, with a negative pressure in the pleural cavity.

TABLE 1.—RELATIVE EFFECTIVENESS OF THREE METHODS OF TREATMENT

	Intercostal Drainage	Rib-Resection Drainage	Philips' Apparatus
Days to produce a completely expanded lung..	50 days	40 days	3 days
Average day of complete stoppage of drainage in two cured cases of each group	42d day	28th day	15th day
Percentage mortality encountered in cases of straightforward empyema (no coincident active pneumonia being present)	30	9	0

At the base hospital at Camp Mills, our empyema experience was similar to that elsewhere. The cases in the spring of 1918 showed a mortality of 55.5 per cent., which was neither good nor bad as compared with statistics from other cantonments. All of these cases were treated by the surgical department, after the diagnosis had been made in the medical department. Those that recovered drained for sixty days in some instances, some patients being discharged in July who had entered in April.

TABLE 2.—EARLY INCIDENCE OF EMPYEMA

Date	Influenza Patients Admitted	Patients Developing Pneumonia	Patients Developing Empyema
Sept. 14	5	1	0
Sept. 15	6	0	0
Sept. 16	3	1	0
Sept. 17	9	2	0
Sept. 18	8	1	0
Sept. 19	20	2	0
Sept. 20	67	3	2

When the first cases of influenza appeared, Sept. 14, 1918, we did not look for much empyema as a complication of the disease, and it was some time before our first case appeared. Our early incidence of influenza was interesting, and is briefly presented in Table 2.

The rapid rise in cases is shown, also the early development of pneumonia and the later development of empyema. Of the ten cases of pneumonia subsequently developing among those admitted during the first week of the epidemic, in two later, during October, empyema developed. Since three of the first ten pneumonia patients died, really the incidence of empyema was two in seven cases.

With admissions rapidly rising, so that we had 3,000 cases under treatment by the middle of October, it was not strange that many later showed signs of empyema. Lieutenant Philips told me of his apparatus, the mechanical details of which were simple, the main thing being a cannula with a sliding curet, and a sliding trocar within it. One or the other could be slipped down at will, the trocar for purposes of inserting the cannula, and the curet for slipping up and down to clean the cannula whenever it happened to be clogged with thick pus. The ideal thing about the apparatus, however, was that it was applied by a glue preparation in an airtight condition to the chest wall and held rigidly in place for days while connected with a Potain aspirator bottle in which a measured negative pressure could be maintained. If the pleural cavity could be thus sucked continuously dry of pus by an apparatus preventing the admission of air into the pleural cavity, so that the lung could be continuously expanded, certainly the ideal treatment would be attained. This the apparatus does. As the pus is sucked out 1 c.c. at a time, the lung expands that 1 c.c., and thus in time the lung is expanded completely.

Those conversant with empyema know that pneumothorax has hitherto been the invariable sequel of every method of treatment except that of occasional and very careful aspiration, such as is practiced in the removal of ordinary pleural effusions. And, indeed, even in many cases of simple and repeated aspiration, the air gets in. Philips' apparatus prevents the development of pneumothorax by way of the external thoracic wall. This is its great advantage.

We now have sixteen such apparatus at our disposal, and our statistics in empyema are improving. In the preceding, Lieutenants Philips and Langmann have set forth the material advantages of this treatment. I might emphasize the principal features: It expands the lungs. It prevents the formation of a pneumothorax by the admission into the pleural cavity of air from without. It provides continuous drainage every hour, minute and second, day and night. It lessens mortality and shortens convalescence. It prevents secondary infection. It is clean, comfortable and sanitary. All the pus is in a bottle, where it can only be seen, not smelled, and where it is harmless. It makes unnecessary an operation (rib resection with the sudden gushing out of a quart or more of pus all over the operating table, dressings and floor) attended with a high degree of shock. It helps to prevent toxic absorption. It leads to very early functioning of an otherwise crowded and crumpled lung.

Too much cannot be expected of the apparatus, but if it merely lessens the mortality of empyema, it is valuable. It cannot prevent the formation of a pneumothorax from within, of course. If, as not infrequently happens, air leaks into the pleural cavity from a bronchus, the apparatus can do no good. It is found wanting, because it is then not possible to exert a negative pressure in such a thoracic cavity. As soon as the apparatus is applied to such a chest, it will suck air through lung bronchus and pleural cavity, as soon as any attempt to make negative pressure is made. But the apparatus has already shown me that most of the pneumothoraces found in empyema are made by treatment and not by ruptured bronchi. Hence not many such cases will be found where the apparatus cannot be applied.

Furthermore, the apparatus cannot prevent the intoxication of the patient by absorption. Some cases of *Streptococcus hemolyticus* infection rapidly become so extremely septic that, before drainage can be instituted, the patients have already absorbed a lethal dose of toxin. It is a mistake to conclude that all patients can be cured by immediate and continuous drainage. Philips' apparatus cannot keep these patients from dying.

For all other cases, however, except these two groups of pneumothorax from within and of extreme sepsis, the apparatus will not be found wanting. It will save many patients who might otherwise die. If it can reduce mortality from empyema by only a few per cent., it is well worth while.

1945 Seventh Avenue.

SEPTIC ARTHRITIS OF THE KNEE ACCOMPANYING FRACTURE OF THE PATELLA

CURE OF A CASE BY IRRIGATION OF JOINT AND STAINING WITH GENTIAN VIOLET

JOHN W. CHURCHMAN, M.D.
NEW HAVEN, CONN.

Since the publication of an article on the "Treatment of Acute Infections of the Joint by Lavage and Direct Medication,"[1] an opportunity has occurred in my service at the New Haven Hospital to make observations, which have amounted to a crucial experiment on a human being, as to the value of this method of treatment. The case was one of pyogenic arthritis, due to *Staphylococcus aureus,* and occurring as a complication of a compound comminuted fracture of the patella. As the boy was admitted to the hospital twenty days after his injury, at which time a purulent arthritis was well developed, and as there was in addition to the comminuted fracture of the patella a large gash below the knee-cap, which on admission had developed into an infected granulating wound, the test of this method of treatment could hardly have been more severe. The result, however, was a complete cure of the septic arthritis; and we were subsequently able to suture the fractured patella—which healed by first intention as though no infection had previously been present—and finally to give the patient a normal leg.

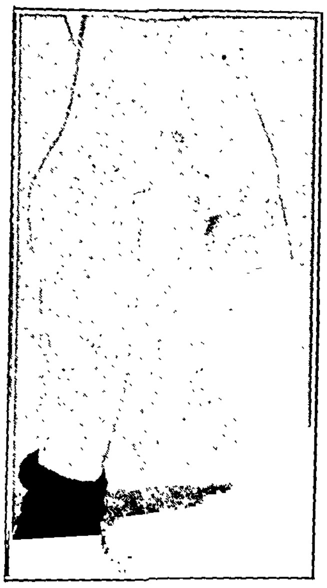


Fig. 1.—Condition of knee after cure of septic arthritis by means of lavage and staining with gentian violet; possibility of complete passive extension without pain; inability to lift foot from the bed (absence of active extension) on account of fracture of the patella.

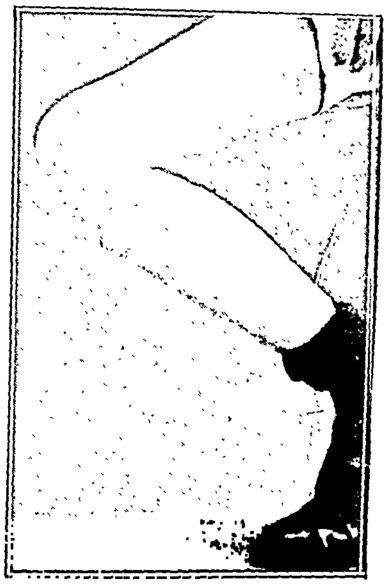

Fig. 2.—Degree of flexion present after cure of septic arthritis.

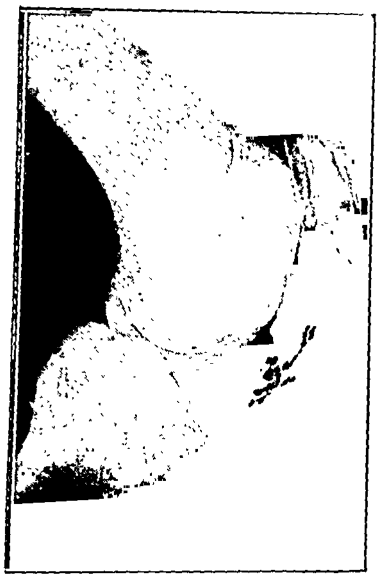

Fig. 3.—Comminuted fracture of patella.

The case was controlled by bacteriologic examinations throughout. The material aspirated from the joint on admission was a bloody pus, and smears from this pus contained a gram-positive coccus. *Staphylococcus aureus* grew out in pure culture. The occurrence of German measles after the first lavage and staining made it impossible to make subsequent bacteriologic observations until about a month had elapsed. At this time fluid was aspirated from the knee and was proved to be sterile, no organisms being found in the smear or on the plants. Meanwhile the incised wound below the patella was gradually cleaning up, and this was allowed to heal and become completely covered with epithelium before operative interference for the fracture of the patella could be thought of. For three days following this aspiration, the incised wound now having been closed for a week, the skin was prepared with benzin and iodin, and a week after aspiration, the joint was opened. It was found to be perfectly normal in appearance and contained the usual glairy synovial fluid, with the slightest possible bloody tinge. Both smears and culture from this fluid were negative. The comminuted fracture of the patella was treated by suturing the periosteal fascia. The knee was put up in a plaster cast and it healed in the usual way.

---

[1] Churchman, J. W.: Treatment of Acute Infections of the Joint by Lavage and Direct Medication, J. A. M. A. **70**: 1047 (April 13) 1918.

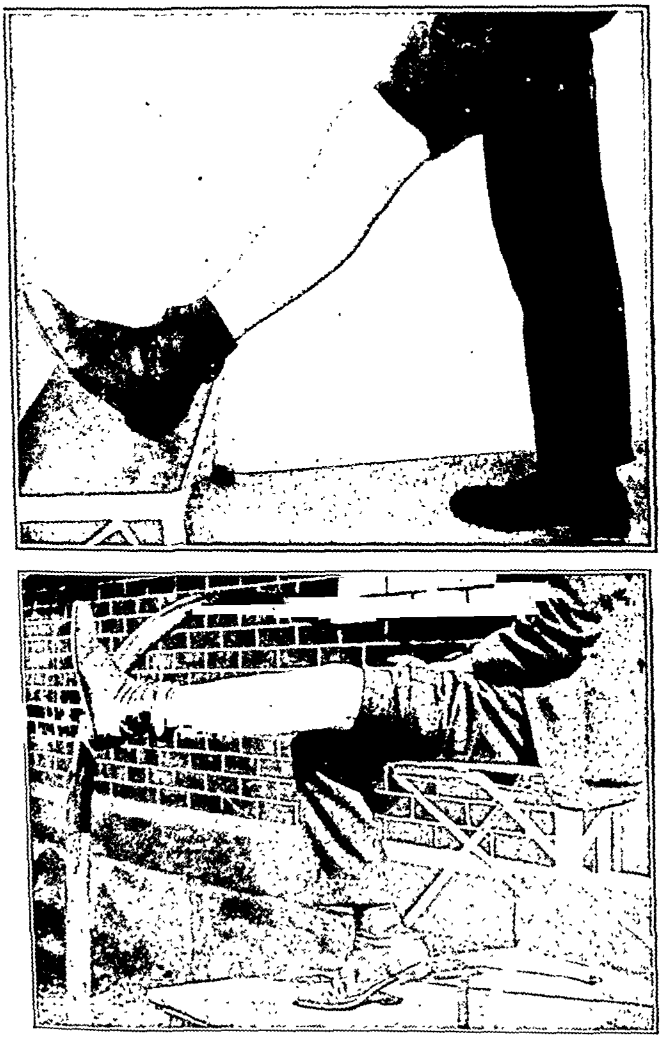

Fig. 4.—Result after suture of patella: active extension normal.

We thus had a septic arthritis, due to *Staphylococcus aureus*, cured by lavage and staining with gentian violet; and a granulating wound allowed to heal in the usual fashion. By means of bacteriologic studies we were able to demonstrate that the lavage and staining had sterilized the joint, and when the healing of the skin wound permitted, we felt safe in opening the joint and suturing the fracture. The bacteriologic studies of the fluid removed at the operation confirmed our opinion that the joint had been sterilized; and this opinion received final confirmation in the absolutely clean healing of the sutured patella and of the skin which followed.

In Figures 1 and 2 the condition of the knee is shown after the septic arthritis had been cured and the skin wound allowed to heal, but before the fractured patella had been sutured. It is to be noticed that at this time, though of course extension of the hanging lower leg was impossible on account of the fracture, the motions of the joint were entirely free from pain even in acute flexion, as shown in Figure 2. The comminution of the patella is shown in Figure 3, and in Figures 4 and 5 the result after suturing the patella. Extension is perfectly normal. Flexion is present to almost its normal degree.

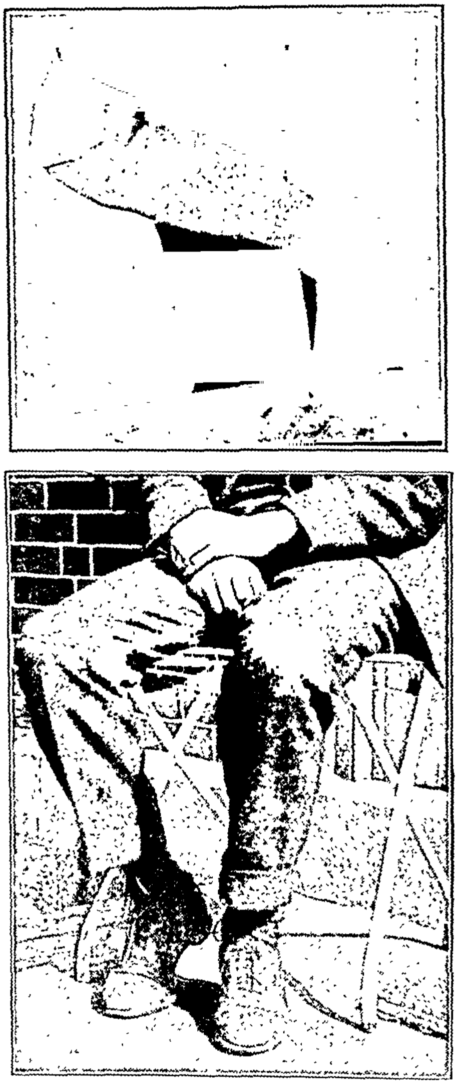

Fig. 5.—Result after suture of patella: active flexion practically normal.

In this patient I have had an opportunity for the first time to see the joint surface in a joint which has been the site of septic arthritis, treated in the manner recently suggested by me. My previous bacteriologic examinations had justified the supposition that by the method of lavage and staining a joint could be sterilized; and the clinical results already reported[1] made it likely that the joint surface, after an infection, when treated by lavage and staining, returns to normal condition. In this patient I was able by actual observation of the joint surface to show that both suppositions are correct. The fluid in this case at the time of operation on the patella was sterile and practically normal in appearance, and the joint surface was entirely normal so far as could be judged by the naked eye.

The temperature chart in this case was so influenced by the occurrence of German measles that it was difficult to draw any conclusions from it. The temperature, however, on admission was 102, and even before the onset of the German measles had reached 103 and was irregular in character. After the lavage and irrigation it fell to 99, and the signs of septic arthritis disappeared; it rose again with the onset of German measles, but was normal at the time of operation. After the operation, at which the patella was sutured, there was never any rise of temperature, the highest point reached being 99.5 on the second day. The temperature fell to normal on the third day, and remained there until discharge from the hospital. The patient is now walking about as he did before the injury.

Clinical Notes, Suggestions, and New Instruments

A REVERSIBLE AND ADJUSTABLE ELBOW SPLINT

Willis W. Lasher, M.D., New York
Lieutenant, M. C., U. S. Army

The accompanying illustrations sufficiently well illustrate this simple brace, so that there remains only a necessity for enumerating some of the advantages of this appliance over the more commonly used types of elbow braces. The same principle may be used in treating injuries in and about the knee joint when forcible flexion or extension is desired. It is to be remembered, however, that splinting is to be used only in conjunction with other means to obtain a result in long standing conditions.

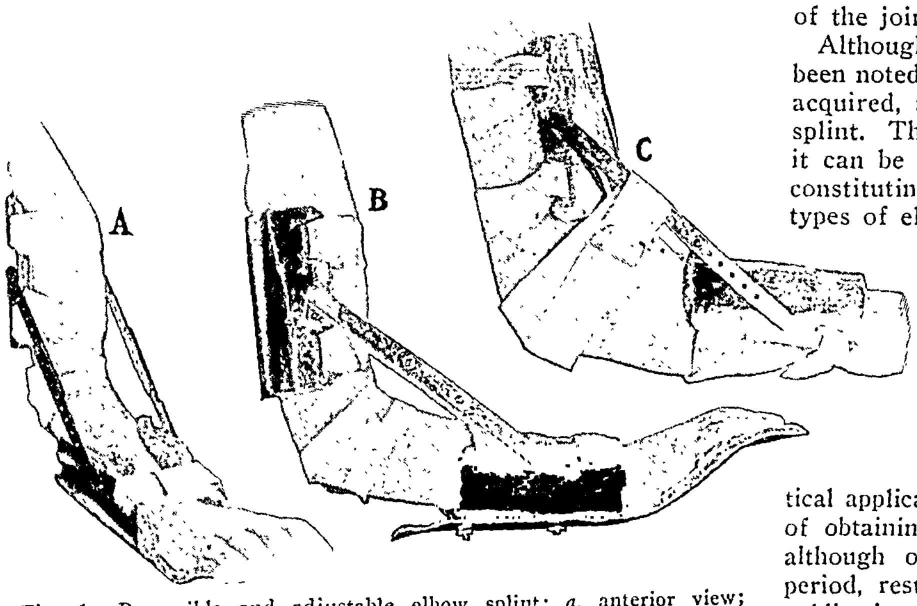

Fig. 1.—Reversible and adjustable elbow splint: *a*, anterior view; *b*, lateral view; *c*, splint applied to the flexor surface of the joint.

Those cases requiring the dressing of wounds about the elbow may be more easily treated with this brace, because no part of the appliance comes in close proximity to this region. Most other splints interfere more or less in the dressing of these wounds, because they depend for their support on a structure placed along the posterior surface of the joint. None of the usual types can be applied to the anterior surfaces of the arm and forearm.

In chronic arthritic conditions or in cases in which limitation of motion has occurred or is apt to occur from any other cause, excepting that due to bony obstruction, the adjustability allows frequent changes of position to be made for the increase of flexion or extension, as the case may indicate. In cases requiring forcible extension, it has been found that, by attaching an additional strap to the rods connecting the two application plates and passing this strap about the posterior surface of the joint, as much *direct* pressure can be exerted as is possible to be satisfactorily borne by the patient. This strap may be made of material of sufficient elasticity to afford a constant traction tending to the desired extension of the joint.

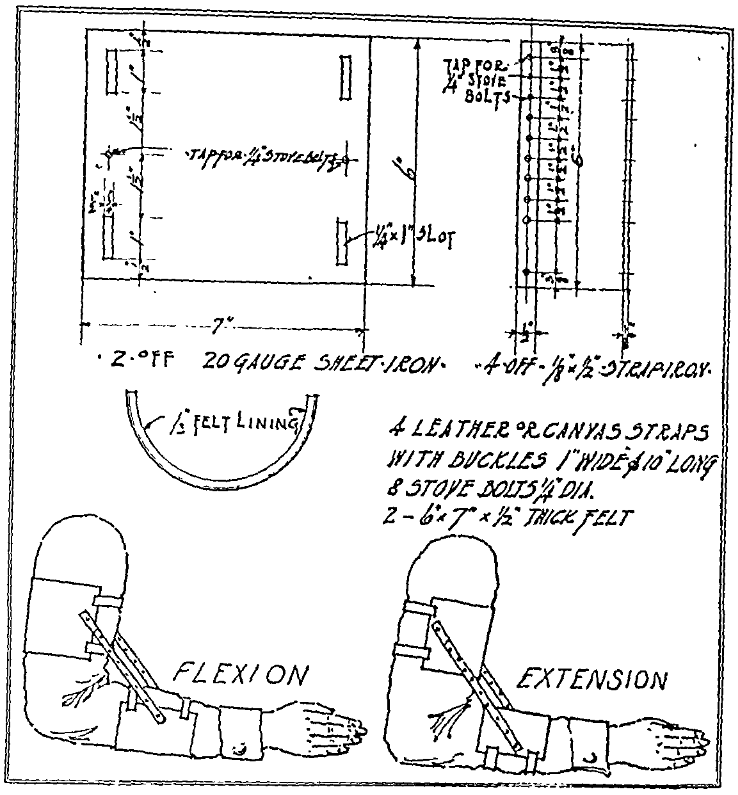

Fig. 2.—Details of splint.

Although it may seem to be of minor consideration, it has been noted that after a sufficient degree of extension has been acquired, a blouse or coat may be easily worn outside the splint. The simplicity of the device and the ease with which it can be made and adjusted must also be kept in mind as constituting a decided advantage over more complicated types of elbow splints.

Owing to the lightness of the splint, it is most comfortably worn. This point is of special importance because of the fact that the heavier appliances or plaster casts exert a constant and undesirable traction on the muscles and structures in and about the shoulder joint.

There are many other desirable points which are more easily illustrated by the use of the splint than described in a lengthy paper. Practical application of this device has been made for the purpose of obtaining flexion and extension of the elbow joint, and although observations have been made over only a short period, results have been sufficiently gratifying to make the publication of this article seem advisable.

Figure 1 *A* shows an anterior view of this splint applied to a compound, comminuted fracture involving the elbow joint. Figure 1 *B* gives a lateral view of the same case and shows how easily a "cock-up" splint may be riveted to the lower, forearm plate, thus affording a combination splint for those cases of wrist drop that are so commonly seen in injuries in and about the elbow joint. Figure 1 *C* shows the splint applied to the flexor surface of the joint.

The Wisdom of Confucius.—It is easier to know how to do a thing than to do it.

STAB WOUND OF HEART: SUTURE OF HEART MUSCLE, WITH RECOVERY

Ethan Flagg Butler, M.D., Yonkers, N. Y.
Major, M. C., U. S. Army

History.—H. M., man, aged 42, roofer, admitted to Ward L-4, Second Surgical Division, Cornell, Bellevue Hospital, Nov. 10, 1918, had received a stab wound in the left chest, from which there was considerable hemorrhage. The family history was negative. The patient had had gonorrhea in youth. Since the age of 18 he had been subject to "fits" occurring on an average of once a month and generally following alcoholic excesses. There was a pronounced alcoholic history with more or less regular Saturday night sprees. Otherwise the history was negative. On the night before admission the patient had been drinking heavily, and on the day of admission at 2:30 p. m. he came home and entered into an argument with his wife. He was evidently abusive, and in self defense, the wife seized a "long, sharp butcher knife" and stabbed him in the chest. The patient bled profusely from the wound and commenced to experience respiratory difficulty. He was, however, able to walk across the street to a police station, where an ambulance was called and the patient brought immediately to the hospital. He was still suffering from dyspnea, pain in the left chest, and inability to lie down, but the early profuse hemorrhage had subsided and there was very slight flow of blood from the wound.

Physical Examination.—The patient was a large, well developed man, with good muscular tone. When first seen he was sitting in a chair, with marked dyspnea; the respirations numbered 40 and were labored. The dyspnea was increased by lying down. The patient complained of pain in the precordial region, the pain being accentuated by respiratory motion. There was moderate cyanosis of the head and the extremities. The pulse was 80 and regular in rate, but apparently of low volume and tension. Over the costal cartilage of the left fifth rib, 6 cm. from the anterior midline, there was a stab wound 2 cm. long with gaping edges. There was evidence on the clothing that there had been profuse hemorrhage from this wound. When seen first in the hospital, there was very slight oozing from it. Examination of the chest disclosed a resonant percussion note over all the pulmonic areas. The breath sounds were normal. There was no evidence of hemothorax. The area of cardiac dulness did not extend beyond the right sternal margin, and extended to the left to the nipple line at the sixth rib. It had not apparently increased in extent. The heart sounds were faint, but there were no murmurs nor other adventitious sounds. The examination was otherwise negative.

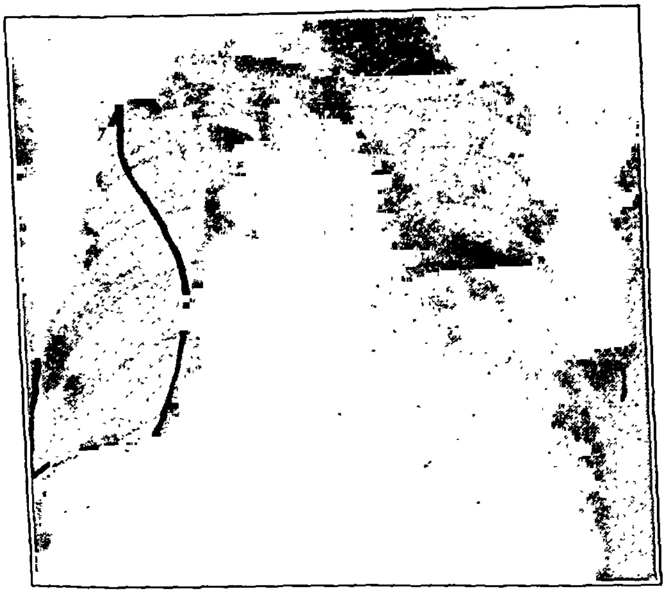

Fig. 1.—Roentgenographic findings forty-eight hours after operation: large left pneumothorax outlined; slight displacement of heart to right.

It seemed advisable to submit this wound to surgical cleansing, on account of the nature of the agent causing it, and the attendant possibility of serious infection. Furthermore, because of the possibility of hemorrhage from the large vessels near the tract of the knife, it seemed prudent to explore the tract thoroughly and tie off any bleeding points.

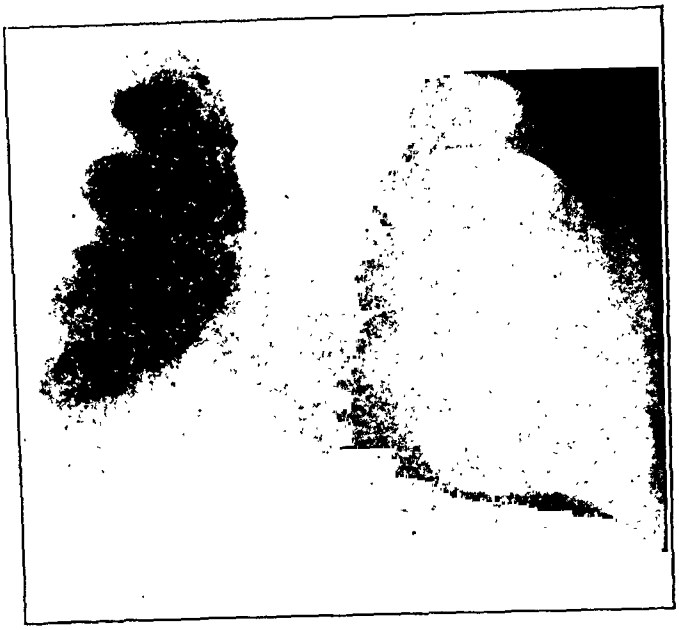

Fig. 2.—Eleven days after operation: left pneumothorax absorbed; heart returned to normal position; very slight left hemothorax.

Operation.—Four and one-half hours after the accident, with the assistance of Dr. M. T. Roote of the Bellevue Hospital house staff, the operation was begun under local anesthesia. The usual procedures of wound excision, with resection of the skin margins, following the tract of the knife through the subcutaneous tissues and the damaged muscle, were carried out. At this point it was discovered that the knife had passed cleanly through the fifth costal cartilage, severing it transversely. A general anesthesia was then employed, and 12 cm. of the fifth rib resected subperiosteally. The left pleural cavity was opened, the left lung collapsing moderately. No injury to the lung could be determined. Below the point of damage to the fifth cartilage there was a puncture wound through the pericardium 1 cm. in length. From this puncture wound, there was a slow, moderate flow of dark blood, and there were found in the left pleural cavity about 100 c.c. of blood. The opening in the pericardium was enlarged by a longitudinal incision 4 cm. long. A slight amount of clotted blood was found in the pericardial sac, anteriorly. There was no general hemopericardium. In the anterior wall of the left ventricle, there was a wound 1 cm. long extending for an unknown distance into the heart muscle, but apparently not penetrating into the cavity of the ventricle.

On opening the pericardial sac, there was a recurrence of severe bleeding from the wound in the heart, the blood flowing in large spurts synchronous with the contraction of that organ. This could be easily controlled by pressure, but immediately recurred on the release of pressure. Apparently this bleeding was from the muscular wall of the heart, the blood being quite dark. At this point in the operation the heart rate was much accelerated, and it was with great difficulty that two catgut sutures were introduced into the wound in the heart. As soon, however, as these sutures were secured in place, all bleeding ceased. Very little blood had escaped into the pericardial sac, and after the excess had been removed the defect in the pericardium was closed by continuous catgut sutures. However, during the suturing of the heart muscles a considerable amount of blood had escaped into the left pleural cavity. On account of difficulty with the aspirating outfit, it was impossible to remove all of this blood without recourse to sponging, which caused respiratory distress and had to be abandoned. Therefore an excess of blood — about 300 c.c. — was allowed to remain in the pleural cavity and the wound in the chest wall was closed tightly in layers — parietal pleura, with intercostal muscles, pectoral muscles, subcutaneous tissue and skin. One rubber tissue drain was introduced into the wound as far as the pectoral muscles.

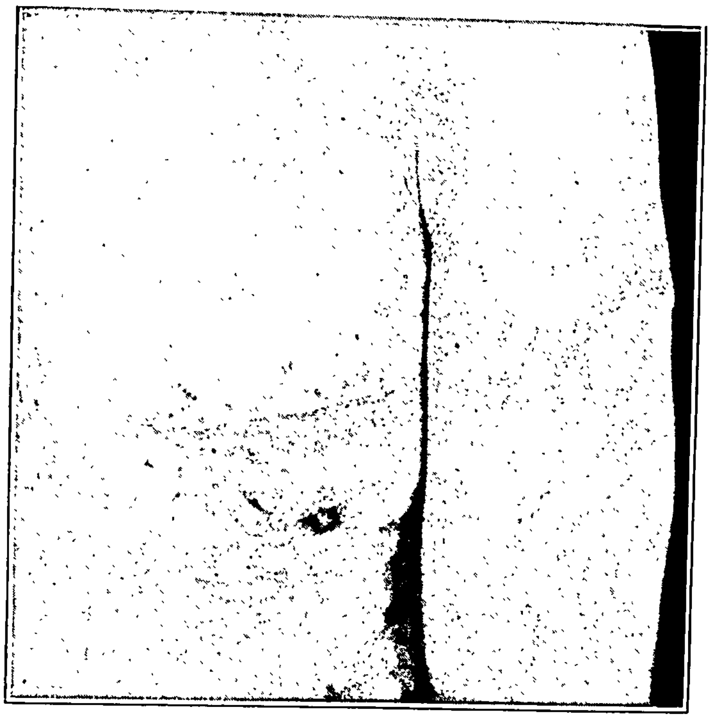

Fig. 3.—Appearance of wound twelve days after operation: primary union; all stitches removed.

The patient stood the operation well and recovered satisfactorily from the anesthetic.

Postoperative Course.—November 11, the temperature rose to 100.5 and remained irregular during the day. The respiration varied from 18 to 32, the pulse from 62 to 94. Cyanosis was less marked. The general condition satisfactory. The heart sounds were apparently normal and distinct. The percussion note over the left chest was tympanitic, except in the axilla and posterior base, where it was decidedly dull, on account of blood which had not been entirely removed at the time of the operation. The chest was aspirated, and much dark, frothy blood was removed.

November 12, the temperature varied from 100 to 100.5, the pulse from 80 to 100, and respiration from 20 to 26. The systolic blood pressure was 128 and the diastolic 76. The patient was much less cyanotic, and there was less pain. The general condition was satisfactory.

The temperature reached normal on the fourth day after operation, and except for one slight exacerbation has remained normal since. The blood pressure has varied from 114 to 118 on subsequent reading. The pulse gradually steadied down to an average rate of 80. The respiration subsided to 18. Precordial pain disappeared rapidly and was not complained of after a lapse of five days from the operation. The left pneumothorax very rapidly disappeared. Roentgen examination eleven days after operation detected no trace whatever of this pneumothorax. The patient was kept in bed for one week after operation and then allowed to get up in a wheel chair without any untoward occurrence. Convalescence from that point was uneventful. The wound healed primarily, and sixteen days after operation the patient was transferred to the convalescent home at Burke Foundation, White Plains.

After his return from the convalescent home, he reported back to Bellevue Hospital for observation, and was found to be in a wholly satisfactory condition.

THORACOTOMY: A SIMPLIFIED TECHNIC

Waller O. Bullock, M.D., Camp Zachary Taylor, Louisville, Ky.
Major, M. R. C., U. S. Army

The recent occurrence of epidemic diseases among the new troops in some of the cantonments was associated with an unusually large number of cases of pleural effusions, many of which developed into empyema. A large percentage of these empyema patients required surgical intervention. Some were successfully treated by aspiration alone.

At the base hospital, Camp Zachary Taylor, Ky., out of 128 cases of empyema, for the most part of hemolytic streptococcus origin, treated by open operation, up to the first day of May of 1918, in fifty-five rib resection was performed, and in seventy-three, simple intercostal thoractomy was done. In the first group there occurred seventeen deaths, corresponding to a mortality of 30.9 per cent., while in the second group, eleven deaths occurred, giving slightly less than half the death rate of the former group, or 15 per cent.

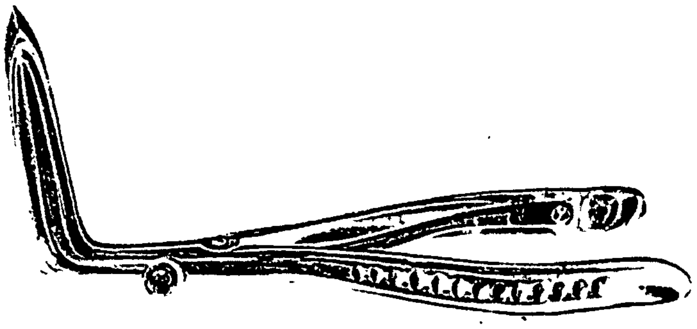
It is not, of course, contended that thoracotomy without rib resection is responsible for this difference in mortality. There are other factors involved, chief of which are the virulence and extent of the invasion, the power of resistance of the patient, and the time that elapses between the occurrence of the effusion and its evacuation surgically. A mortality of 40 per cent. in patients operated on within twenty-four hours of the appearance of the septic effusion (pus or seropus) should be compared with a death rate of 10 per cent. (four deaths) in forty-two cases having an average interval of between nine and ten days between the appearance of fluid and its surgical evacuation, simple thoracotomy being the procedure in the latter group.

If, therefore, at least equally good results may be obtained by the simpler procedure, it should for obvious reasons be preferred. With the object of further simplifying the technic of the operation, the instrument herein illustrated was devised. It is made out of forged steel, following in general plan the Bodenhamer rectal speculum, but having one blade longer and wider than the other. The larger blade has cutting edges for the terminal inch and a half, and tapers to a sharp point. The other blade is narrower, one-half inch shorter, and its blunt end fits into the concavity of the larger blade.

The length over all is 8 inches, the handles measuring 6 inches from the lock. The longer blade is 3 inches long and three-fourths inch wide at the base.

The technic employed in brief is as follows:

1. The pus is invariably located by means of exploratory puncture, and note is taken of the depth at which it is encountered before the needle is withdrawn.



Instrument for simplifying technic of thoracotomy.

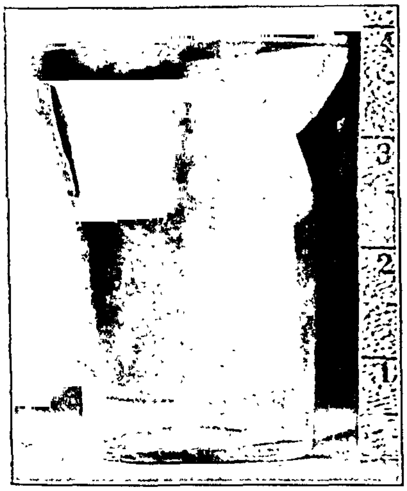
2. The skin is anesthetized at the point so determined for a length of 2 inches, the intercostal space being paralleled and incision being made with knife or scissors.
3. All structures to be penetrated are thoroughly infiltrated with either 0.2 per cent. solution of cocain, procain or cocain substitute.
4. With closed blades under gentle pressure the instrument is pushed between the ribs to a depth one-half inch beyond the point at which the pus was located and the blades separated by closing the handles. The set screw will hold the blades open to an extent sufficient to introduce a drainage tube of any size, even a Brewer tube with a small flange.

The procedure is thus reduced to a simple puncture of the chest wall; but its successful execution depends on the thoroughness with which local anesthesia is carried out.

A GLASS TUMBLER IN THE RECTUM

Orvall Smiley, M.D., Indianapolis

The unusual features of this case are the size and shape of the glass tumbler. C. K., a man, aged 55, entered the Indianapolis City Hospital, March 10, 1919, at 2 p. m., saying that about fifty hours before, with the assistance of a woman, he had introduced a small glass into the rectum for the purpose of exciting sexual passion.



Glass tumbler removed from rectum.

When I was called to the hospital I found him in shock with rapid pulse and rising temperature. I could feel one side of the thin edged glass tumbler tightly wedged about 4 inches up in the rectum with the mouth down, into which had rolled the edematous rectal mucosa, making it impossible to move the glass down by traction.

I opened the abdomen, found a beginning peritonitis, and after opening the rectum I first tried again to push the glass down out of the anus, but could not move it. The glass was then removed with great difficulty from above. The bulge of the glass acted as an obstruction in pulling it out through the pelvis. The top diameter of the glass was $3\frac{1}{16}$ inches, the bottom diameter 2 inches. It was 4 inches high. The two small pieces broken from the top edge facilitated its removal to a degree. The patient died sixteen hours later.

219 Newton Claypool Building.

REPORT OF A CASE OF STEEL IN THE LARYNX

Frank Allport, M.D., and Bryed Wilson, M.D., Chicago

This case is reported, not to expound any new or special surgical technic or diagnostic methods, but rather because it is unusual.

REPORT OF CASE

History.—J. B., man, aged 40, who came to our office, Nov. 2, 1918, reported that on April 19, 1918, while at work in a steel mill shearing tie-plate bars, a fragment of the steel tie-plate flew and struck him on the neck below the point of the chin. He was taken to a hospital where the wound was sutured, and he was treated for about ten days and then returned to work. Since the accident he said that he could not talk above a whisper; and at the time he consulted us his voice was a coarse, rough whisper.

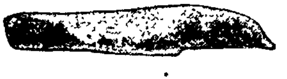


Fig. 1.—Piece of steel, actual size, removed from larynx; weight, 90 grains.

Examination.—The scar of a wound extended from beneath the point of the chin downward and a little toward the left until it reached the level of the larynx. A slight prominence, somewhat conical in shape, at the left lower aspect of the thyroid cartilage of the larynx, was somewhat adherent to the overlying skin, and felt solid to the touch and moved with the larynx. Indirect laryngoscopy revealed an immobility of the left vocal cord, and the whole larynx was moderately inflamed. A roentgenogram disclosed a piece of metal about $1\frac{1}{4}$ inches in length extending anteroposteriorly and apparently through the left thyroid cartilage of the larynx.

Operation and Result.—The patient was taken to St. Luke's Hospital, and under procain local anesthesia an incision was made over the prominence spoken of above. Immediately after going through the skin and subcutaneous tissue, the scalpel came in contact with a hard metallic substance. By careful dissection, the end of the piece of steel was exposed and grasped with tissue forceps. The anterior end of the steel was freed from a few fibrous attachments by means of a small periosteal elevator, and the steel was gently and easily withdrawn. There was, fortunately, no hemorrhage or other undesirable complications. The incision was closed by one silk suture. The man was placed in bed under a steam tent and carefully watched throughout the next twelve hours and was not allowed to talk. During that time he had had no troublesome symptoms whatever, and now when he was asked a question he replied in a voice that was hoarse but was a speaking voice and not a whisper, as had been the case prior to his operation. He left the hospital in two days, and at the end of a week his voice was a little rough but almost normal. Since then the roughness has disappeared. On examination by indirect laryngoscopy, the vocal cords are normal in appearance and the left cord again moves normally.

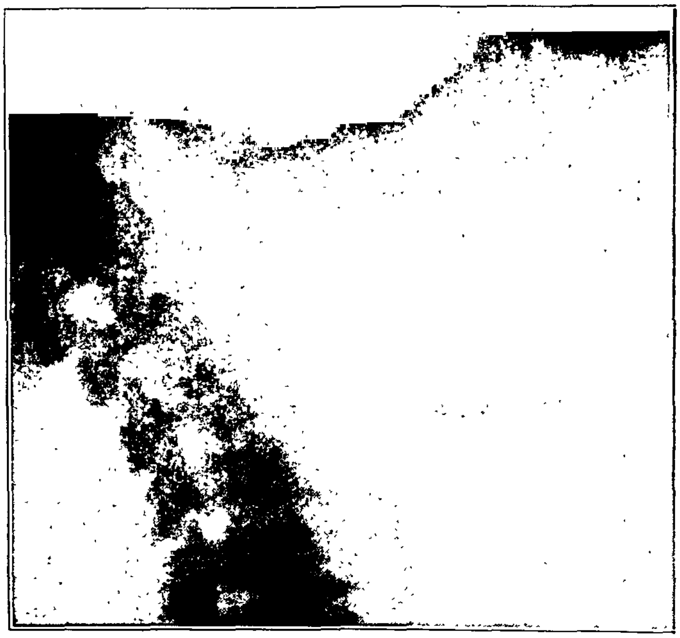

Fig. 2.—Lateral view of steel fragment in wall of larynx.

COMMENT

It is probable that the steel had not actually penetrated into the interior of the larynx but had lodged in the cartilaginous wall, so to speak, in such a manner as to immobilize the vocal cord of that side, and the removal of the steel allowed the cord again to functionate and the patient's voice recovered its normal tone.

7 West Madison Street.

Adaptability of Breast Milk.—There is no such stability in the breast milk as in the milk formula in the bottle. It changes not only several times a day and during each nursing, but is influenced and determined by the frequency of nursing, length of nursing and vigor of nursing, that is, it adjusts itself to the kind of baby and the condition of the baby at the breast. How valuable this is when the baby is not feeling well, or needs less energy food, as in summer, all who treat babies know [illegible] while a milk [illegible]ying laborat[illegible] looks impressive wi[illegible] pasteur[illegible] and instrume[illegible] precision, it is not [illegible]le to th[illegible]ate laborator[illegible] mother's breast. [illegible], M[illegible]

MENINGOCOCCIC ENDOCARDITIS: REPORT OF CASE

Murray C. Stone, M.D. (Springfield, Mo.)
Major, M. C., U. S. Army
and
Walter D. Brown, M.D. (Beaumont, Texas)
First Lieutenant, M. C., U. S. Army
CAMP LOGAN, TEXAS

History.—G. A., man, aged 24, with negative family history, had had the usual diseases of childhood, except scarlet fever and diphtheria. Since childhood he had been in perfect health. His present illness began about 4 p. m., Nov. 28, 1918. He had a severe frontal headache, fever and sweats. His symptoms continued during the night, the headache allowing him to get very little rest. The next morning, in addition to the headache, which was about the same, he had severe pains in the calves of the legs. He remained in quarters during the day and the following night. On the morning of November 30 he noticed an eruption on the eyelids and on the trunk, arms and thighs. He was admitted to the base hospital at 8 a. m., November 30. When seen shortly afterward his headache was better, the aching in the legs had disappeared, he had no cold nor cough, his appetite was poor, and he felt feverish.

Examination.—The patient was well developed, and weighed approximately 180 pounds. His mentality was clear. He appeared slightly depressed, but not irritable or nervous. The only striking objective sign was the purpuric rash, which was macular, about 0.25 to 0.5 cm. in diameter, and very scattered. It appeared on the upper eyelids, the shoulder and the pelvic girdle, arms, hands and thighs. The reflexes at this time showed nothing remarkable. The buccal mucous membrane and the throat were red. All other physical signs were negative.

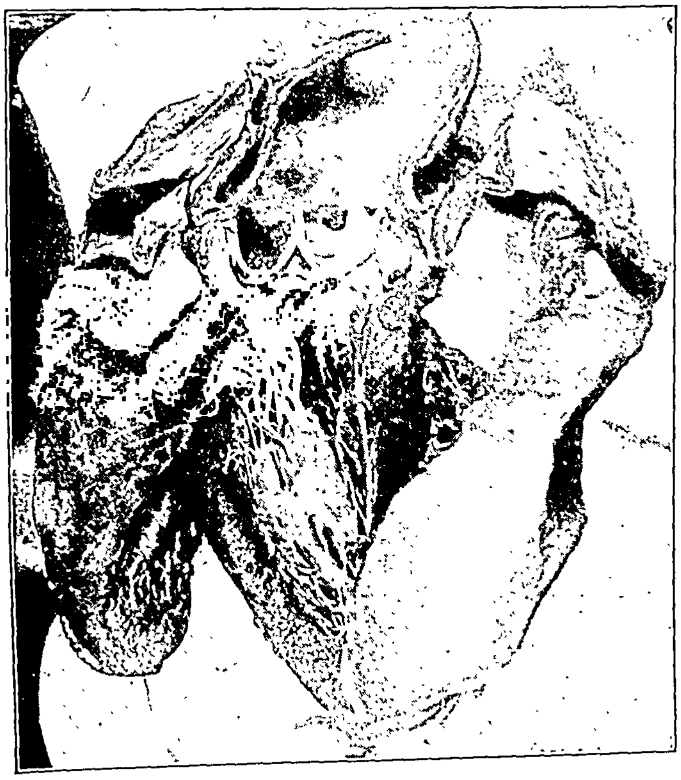

Fig. 1.—Photograph of the heart, showing aortic valve with extensive lesion on one cusp. On the inner surface of the cusp is seen a vegetation, while at the base of the outer surface there is a small, deep ulceration. Smears from this showed many meningococci.

Treatment and Course.—Shortly after admission, lumbar puncture yielded 40 c.c. of fairly cloudy fluid under strong pressure. Thirty c.c. of antiserum were administered intraspinally and 1 c.c. hypodermically as a desensitizing dose. An hour later, 120 c.c. of antiserum were administered intravenously. Daily intraspinal and intravenous injections, in the same amounts as stated above, were administered up to December 6. During this time the patient showed gradual improvement. The spinal fluid cleared and became free of meningococci. His appetite improved, and he was comfortable except for the serum urticaria which appeared, December 5. Neck stiffness and Kernig's sign appeared after the first treatment, and persisted until the end.

No other notable change occurred until December 10, when the routine morning examination revealed a purpuric spot about the size of a dime on the dorsum of the right hand, and another on the outer surface of the left ankle. The patient had rested well during the night and remained comfortable until noon, when he developed a severe headache, together with numerous additional purpuric spots on the hands and feet. Lumbar puncture revealed a cloudy fluid under rather low pressure. Daily intraspinal and intravenous treatments, as before, were given for three days, with about the same degree of improvement. The next relapse occurred, December 14, and was again preceded by a purpuric rash. The symptoms during this recurrence being rather mild, and the patient's reaction to antiserum being more intense, he received only one intraspinal and one intravenous injection. The next exacerbation was December 20 and was preceded by purpuric spots on the hands, elbows, knees and feet. The spinal fluid was slightly cloudy. Thirty c.c. of antiserum were given intraspinally. The intravenous treatment, though administered very slowly, had to be almost immediately discontinued owing to a most violent reaction.

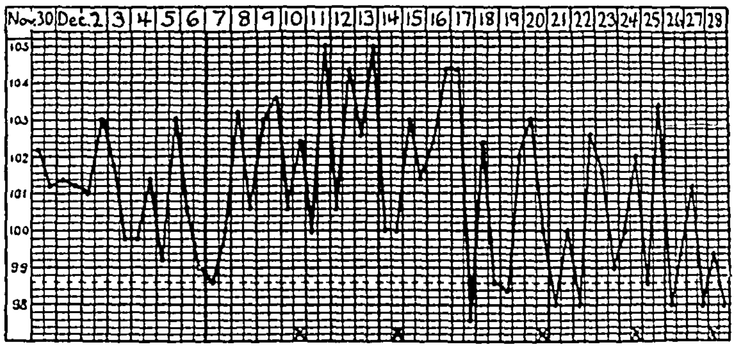

Fig. 2.—In addition to furnishing a good example of a "septic temperature curve," this chart shows how each crop of petechiae was preceded from twenty-four to forty-eight hours by a rise of temperature.

From this time on the patient's condition became gradually worse. Intraspinal injections were given from December 20 to December 24, inclusive.

December 27, another crop of purpuric spots appeared. There was marked mental apathy. Lumbar puncture gave 45 c.c. of bloody fluid. Thirty c.c. of antiserum were given intraspinally. The patient's condition being so desperate, it was considered advisable to give serum intravenously at all hazards. One hundred and forty c.c. were so administered in spite of the patient's becoming violent and dyspneic. The same treatment was repeated, December 28.

December 29, another crop of spots appeared, not so intense in color. The patient sank rapidly, and died at 11:45 a. m. The total amount of serum administered was 1,725 c.c.

Laboratory Findings.—The routine examinations showed a normal urine; the feces were free from parasitic ova, and the throat culture was negative for hemolytic streptococci.

Spinal Fluid: At the first puncture, 40 c.c. of turbid fluid were obtained, showing much pus and a moderate number of meningococci in the smears. Cultures and agglutination test revealed the organism to be a normal meningococcus Type I. A potency test of the treatment serum used in the case was made with the strain of organism causing the infection. Agglutination was obtained in a 1:400 dilution. Specimens of spinal fluid from subsequent punctures gave the showings seen in the accompanying table.

Necropsy.—Body: The patient was a white man, well developed and fairly well nourished. Rigor mortis was present. The skin of the trunk and the limbs showed numerous small red petechiae, and many small, faintly brownish spots, evidently the site of earlier lesions of a similar nature.

Head: The membranes over the convexity of the brain were moderately congested, but showed no exudate nor excess of fluid. The base of the brain about the circle of Willis, and over the surface of the pons, showed a moderate amount of yellowish exudate beneath the pia, which itself was thickened and adherent. The fluid escaping from the spinal canal was moderately in excess, but not especially cloudy. There were numerous minute hemorrhages over the surface of the cerebellum near the pons. The dura covering the base of the skull was noticeably injected, but showed no exudate.

Spinal Cord: The cord and membranes showed practically no gross changes. An occasional small ecchymotic spot was seen beneath the pia. No lesions were noted in the cauda equina. There was some ecchymosis in the muscles at the site of the lumbar punctures.

Abdomen: The peritoneum was normal. The intestine was distended with gas. The bladder was full. The liver was at the costal border.

Pleural cavities: These were free.

Lungs: These were voluminous and filled with air. There was an old scar at the right apex. There were atelectatic areas at the right base.

Pericardium: There were numerous small ecchymoses. The membrane lacked the usual luster, and the sac contained a few drops of a viscid, yellowish exudate.

Heart: There was a slight enlargement, apparently due to hypertrophy of the left ventricle. All the cavities contained fibrin clots. The valves were normal, with the exception of the aortic. The posterior cusp was the site of a pinkish, irregular vegetation, fleshlike in consistency, and with a broad base measuring 1 cm in diameter. The edge of the cusp was free, the lesion occupying the base and involving both surfaces. The outer portion of the lesion was ulcerated into the heart wall for a distance of several millimeters. Other minute vegetations were seen on this and the adjacent cusps. There were a few small atheromatous areas on the ascending aorta.

LABORATORY FINDINGS IN THE SPINAL FLUID

Date	Amt. of Fluid, Cc.	Pus	Organisms (Smear)
Dec. 2	30	Present	Present
Dec. 3	40	Present	Absent
Dec. 4	40	Present	Absent
Dec. 5	40	Present	Absent
Dec. 10	35	Present	Present
Dec. 11	45	Present	Absent
Dec. 12	30	Slight	Absent
Dec. 18	40	Present	Present
Dec. 21	35	Slight	Absent
Dec. 22	40	Slight	Absent
Dec. 23	30	Slight	Present
Dec. 27	40	Present	Absent

Spleen: This was two and a half times normal size, very soft and rather pale.

Liver: The liver was pale brownish, not enlarged, and with consistency diminished.

Pancreas: There was nothing worthy of note.

Stomach: There were a few petechial spots beneath the peritoneum, and also in the omentum.

Intestine: This showed nothing remarkable.

Kidneys: These were large and injected, with indistinct markings and numerous small hemorrhages beneath the pelvic epithelium.

Bacteriologic Findings: Smears from the ulcerated base of vegetation on the heart valve showed many gram-negative diplococci.

Anatomic Diagnosis: Leptomeningitis and pachymeningitis (subacute) of the brain and spinal cord were diagnosed. Incipient pericarditis and acute (aortic) endocarditis were found. Petechiae of the skin, the stomach, the omentum and the pelvis of the kidneys were present.

The cause of death was cerebrospinal fever.

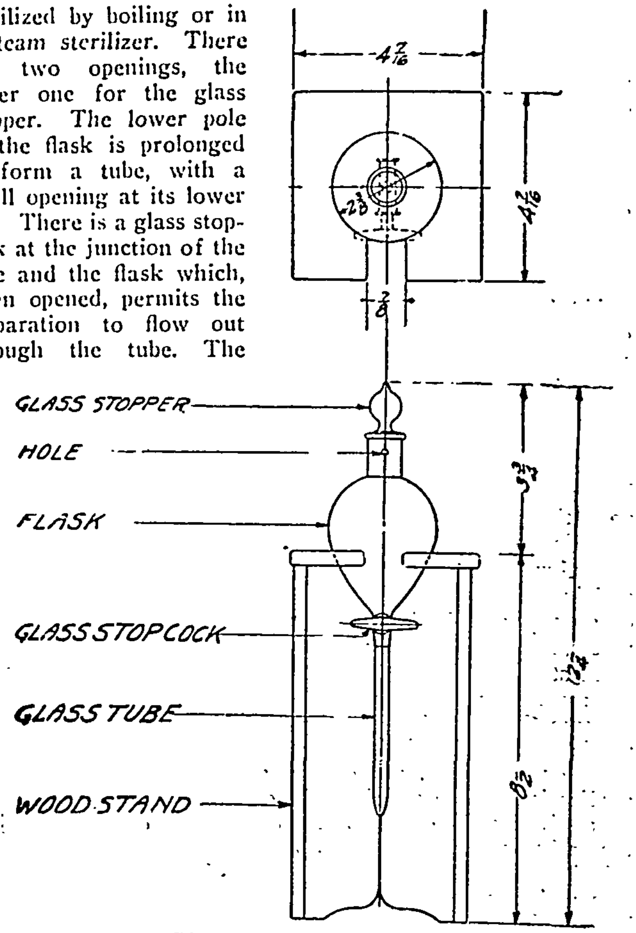
Genius and Eugenics.—Statistics show that genius knows no caste. Men of great achievements originate in all classes in about equal percentages—they cannot be bred. If eugenics plays a part, its influence is greatly overshadowed by other factors. Getting the right start and then giving full play to one's bent are the vital factors in developing capacity for great achievement.—Dr. P. G. Nutting, *Scientific Monthly*, November, 1918.

DICHLORAMIN-T CONTAINER

M. B. Cooperman, M.D., Philadelphia
Assistant Orthopedic Surgeon, Polyclinic Hospital

Those using dichloramin-T have difficulty in applying the solution because of an unsatisfactory apparatus. Atomizers, syringes, medicine droppers and even bottles containing the solution have been used, but all have their faults. Owing to the density of the liquid, it is rather difficult to spray dichloramin-T through an atomizer. Syringes are unsatisfactory because they entail too frequent handling; they are time consuming in drawing up the solution, and contamination of the instrument is very likely. Pouring the liquid from a bottle is crude, while the medicine dropper is very unsatisfactory.

The apparatus here illustrated has proved satisfactory. The container is a pear-shaped glass flask having a capacity of 4 ounces. There are no rubber connections. It can be easily sterilized by boiling or in a steam sterilizer. There are two openings, the upper one for the glass stopper. The lower pole of the flask is prolonged to form a tube, with a small opening at its lower end. There is a glass stopcock at the junction of the tube and the flask which, when opened, permits the preparation to flow out through the tube. The stopper is of blown glass. There is a small hole in the neck of the flask and in the stopper. When the flask is closed and the stopcock opened, the liquid runs out slowly. By turning the stopper until the two holes are in apposition, the air pressure within the flask is increased and the flow of dichloramin-T is thereby accelerated.



Dichloramin-T apparatus.

The solution cannot be contaminated by dust or air while in the flask.

The dichloramin-T flask is kept on a small white enameled wooden stand. It rests snug in its place and cannot fall off.

When a wounded area is to be treated, the flask is lifted out of its stand and carried to the patient. The stopcock is opened and the liquid flows slowly or rapidly at the will of the operator, over and into the wound, bathing every recess.

The same apparatus, but of greater capacity, is used as a container for neutral solution of chlorinated soda.

The advantages in the use of this apparatus are: (1) convenience in treating wounds; (2) simplicity of construction; (3) avoidance of contamination of the dichloramin-T, and (4) the saving of time which its employment effects.

1811 South Broad Street.

PAINLESS INCISION BY THE USE OF PURE PHENOL

A. L. Soresi, M.D. (New York)
Surgeon in the Ospedale Militare Principale, Italian Army
Milan, Italy

Incision of tissues, even deep ones, can be made painlessly by dipping the scalpel in pure phenol (carbolic acid). Incisions made in this manner will not be followed by even the smarting sensation which follows incisions made by other methods.

TECHNIC

A dry, sterile scalpel is dipped in pure phenol. The point of the back of the scalpel is passed over the intended line of incision, so as to mark it with the phenol. A few seconds later the scalpel is dipped again in the phenol and the tissues are incised very slowly and gently, the scalpel being moved up and down as in cutting with a saw. When blood appears, a sponge is used or blunt retractors are applied, if necessary, the scalpel being dipped in pure phenol as often as required. By this method a film of the phenol is deposited on the blade; this film comes in contact with the tissues as they are cut, and thus anesthetizing them. This film is rubbed off by the tissues or washed off by the blood through which the blade passes, and therefore has to be renewed by dipping the scalpel in the acid as often as is necessary, according to the depth of the tissues to be incised.

ADVANTAGES OF THE METHOD

Absolutely painless incisions are obtained of even very deep tissues, such as the pleura, culdesac of Douglas (four cases), etc. Over 100 pleurotomies have been done by this method, during the last epidemic of influenza, by Professor Buschi of Como, Italy, and the writer. It is the least dangerous method of anesthesia, either local or general. The method has been applied in over 3,000 cases and there has never been the slightest indication of absorption or even slight poisoning from its use. It is the easiest method to apply and the one method which can be applied in all cases and which will always work, even when the tissues are most inflamed and in cases in which either local anesthesia is not possible or general anesthesia is contraindicated. Some of the pleurotomies have been done in patients who were in a moribund state and the results have been most gratifying. It is the most convenient method and the one least feared by the patients, for phenol is found anywhere, and no special preparation, not even painting the skin with iodin, or any instrument or apparatus, not even a syringe, is required for its application. Naturally it is the cheapest method imaginable. *In a given class of cases it promotes the complete cure of the pathologic condition.*

This statement is most important and requires special mention and some explanation. Incision made with the phenolated scalpel, on account of the slight cauterization of incised tissues produced by the phenol, do not close as rapidly, as incisions made with the untreated scalpel. This was at first thought to be a very serious inconvenience; in practice, however, it has proved to be one of the best points of this method. In fact, any tissue that is incised, the cut edges of which need not adhere immediately, as is the case when a collection of pus has formed or the tissues are highly infected and inflamed, as in cellulitis, or in the presence of a foreign body embedded in the tissues, the too early closing of the cut edges is prevented and the exit of the pus is facilitated by the insertion of gauze, rubber, tubes, etc., which in certain parts of the body can be placed only with difficulty or cannot be kept in the desired place and always act as foreign bodies with all their undesirable results. When the incision is made with the phenolated scalpel all these means become absolutely unnecessary and the complete cure is rendered more easy, painless and more rapid, while the cosmetic results are also much better. This method of incision finds its best indications in cellulitis of the limbs, collection of pus in Bartholin's glands, in the posterior culdesac of Douglas, in or around the gums, the anus, the neck, the face, the axillae, the groins, etc., in which cases the simple incision made with the phenolated scalpel and the wet dressings or frequent washings with warm liquid constitute the whole treatment, which is both complete and rapid.

The phenolated scalpel, for obvious reasons, should not be used when reunion by first intention and suture are desired. The scars produced by the phenolated scalpel are never ugly; in fact, they are much better than those resulting in cases in which drainage was necessary. A slight redness along the incision lasts at times for some days, but disappears completely in a short time.

REPORT OF CASE OF SEPTIC SINUS THROMBOSIS WITHOUT INVOLVEMENT OF THE MASTOID

St. Julien R. de Caradeuc, M.D., Savannah, Ga.

History.—Private S. B., aged 23, was admitted to the hospital, Jan. 14, 1919, with influenza. January 18 he developed measles; January 30 otitis media purulenta acuta of the right ear; January 31 otitis media purulenta acuta of the left ear. Myringotomy was done in each case the day of the development of the acute ear trouble, and irrigations of boric acid solution every two hours were ordered.

The course of the patient's illness was such as would be expected with this complication of diseases and the temperature ranging irregularly from 98 to 104.

February 14, the patient was transferred to the ear ward, as the influenza and measles had subsided and there was no clinical evidence of any disease aside from the discharge from the ears.

February 18, both ears were dry, and on examination the drums presented the appearance of resolution.

February 20, the patient complained of discomfort over the left side of the face, and kept the head covered the entire day. There was no headache. The blood count was: 15,000 leukocytes; 79 per cent. polymorphonuclears.

February 23, the patient had a definite chill lasting about twenty minutes, followed by a rise of temperature to 105.2 (by mouth), accompanied by severe frontal headache, and followed by a profuse sweat. The blood count was: 23,300 leukocytes; 93 per cent. polymorphonuclears. The blood culture was positive for *Streptococcus hemolyticus.*

Physical Examination.—The heart and lungs were normal. The liver and spleen were normal. There was slight inequality of the pupils. The reaction to light was normal. Knee-jerks were slightly exaggerated but were the same on both sides (this had been the case for over three weeks). There was partial ankle clonus on the left side, and complete on the right side. Examination of the urine disclosed some pus cells and a slight trace of blood. Widal test was negative. The blood was negative for malaria. The fundus examination was negative.

February 24, the patient complained of headache, general in character and not confined to any special point or region. At noon he had a severe chill lasting thirty minutes, followed by a temperature of 104.6. Examination of the ears at this time showed the right drum to be normal in appearance with good inclination and light reflex normal. The left drum showed much the same appearance except for absence of the light reflex and a slight dulness. This was the second ear to become involved, and this difference in appearance might perhaps be accounted for in this way. Both drums presented the appearance of a resolving acute otitis media. There was absolutely no mastoid tenderness at this time or at any time during the course of the illness. The blood count was: 38,000 leukocytes; 94 per cent. polymorphonuclears. The blood culture was negative. The physical examination and the urinary examinations were also negative. The fundi were negative. No lumbar puncture was done.

Operation was decided on, but in view of the urinary findings it was suggested that there might be some kidney condition to account for the septic course the patient was running. A cystoscopic examination was made by the urologist, and the findings were negative.

February 25, the blood count was: 31,200 leukocytes; 94 per cent. polymorphonuclears. The blood culture was negative.

Operation.—A simple mastoidectomy under ether was performed with the following findings: The cortex was thick and very sclerotic. The mastoid cells were normal, and there was no pus even in the antrum.' The sinus was exposed, but as there did not appear to be any definite disease of the sinus, it was decided to uncover and inspect the dura over the temporosphenoidal lobe and cerebellum. This was accomplished after considerable difficulty on account of the ivory-like hardness of the bone and the high middle fossa. Much time was consumed in this way unnecessarily. After exposure of the dura and finding it normal, a further examination of the sinus was made, and, as it appeared paler than normal, it was opened and thick pus exuded and continued to exude as from an abscess. The jugular vein was then resected, after which the sinus was again attacked from the mastoid wound. The diseased walls were cut away, and only the dural wall was allowed to remain. A culture from the sinus showed a pure growth of *Streptococcus hemolyticus*. The vein was normal. The patient made an uneventful recovery.

COMMENT

This case was unusual in that the infection must have spread from the middle ear without involving the mastoid and in that there was a negative appearance of the drum with absolute cessation of the discharge and negative findings in the mastoid. It has been my experience to find great destruction of the mastoid cells when *Streptococcus hemolyticus* is the causative factor, with pain and tenderness over the mastoid negative.

A TEST FOR GLOBULIN IN SPINAL FLUID FOR USE AT THE BEDSIDE [*]

Harold L. Amoss, M.D., New York

Rough tests on globulin solutions showed the isoelectric point to be between p_H 4.4 and 4.7. The p_H value for a 2 per cent. solution of anhydrous potassium dihydrogen phosphate is 4.4. If the globulin precipitation depends on the p_H value of the solution, then a solution of primary phosphate could be substituted for the Noguchi butyric acid sodium butyrate mixture. Various concentrations of the primary phosphate were used, from 2 per cent. to 10 per cent., in testing spinal fluids known to contain excess of globulin, as shown by the Noguchi method. To 0.2 c.c. of the spinal fluid were added 0.6 c.c. of the primary phosphate solution, and the tube containing the mixture was immersed in boiling water for six minutes. The solution acting the most quickly and yielding the largest flocculation was the 3 per cent.; this compares favorably with the Noguchi test.

CHANGE IN p_H VALUE IN BOILING

The p_H values of the mixtures of spinal fluid plus phosphate solution and the mixtures of spinal fluid plus Noguchi's mixture are equal. However, on boiling, the phosphate spinal fluid mixture becomes less acid, as shown by methyl red, while the Noguchi mixture remains unchanged. If the phosphate solution is fortified by the addition of acetic acid so that the p_H value after boiling with the spinal fluid remains about 4.4, the globulin is either not precipitated or the floccules are very minute. Apparently other factors than hydrogen ion concentration enter into the reaction. A 10 per cent. phosphate solution possesses sufficient buffer power to maintain the p_H value during boiling, but the high salt content produces very fine granulation of the globulin. Addition of various amounts of sodium chlorid yields like results. It appears that the globulin precipitation depends not only on the hydrogen ion concentration but also on the amount of salts present.

Spinal fluids tend to become more alkaline even when placed in the ice box over night. For testing such fluids it has been found advisable to add to each 100 c.c. of potassium dihydrogen phosphate solution in 0.05 c.c. of glacial acetic acid.

COMPARISON OF THE PHOSPHATE SOLUTION REAGENT WITH THE NOGUCHI TEST

Through the kindness of Dr. Martha Wollstein of the Rockefeller Institute and Miss Innerstein of the New York City Board of Health Laboratory, twenty-one specimens of spinal fluids were tested with the Noguchi and the 3 per cent. primary phosphate solution plus 0.05 c.c. of acetic acid. Two-tenths c.c. of the spinal fluid was used in each test. In the Noguchi test 0.5 c.c. of 10 per cent. butyric acid in isotonic sodium chlorid solution was added and the mixture heated for two minutes. One-tenth c.c. of normal potassium hydroxid was then added and the tube containing the mixture placed in boiling water for four minutes. The phosphate-acetic acid mixture test was conducted as follows: To 0.2 c.c. of the spinal fluid there was added 0.6 c.c. of the reagent. The tube containing the mixture was placed in boiling water for six minutes. The results of the test are shown in the accompanying table.

The reagent, being less delicate than that of the Noguchi test, gives no precipitate with normal fluids, but consistently indicates fluids in which globulin is present in excess. The reaction requires about two minutes longer heating than is required with the Noguchi test, but requires less manipulation, since one solution is used instead of two. Accurate pipetting of the spinal fluid only is necessary; slight variations in the amount of the reagent added do not affect the end-result. The objectionable odor of the butyric acid is absent; consequently the test can be made in the patient's room. Should small amounts of the solution be spilt in transportation, the diagnostician's kit is not thereby rendered disagreeably redolent. The solution is quickly and easily prepared and is stable, while the Noguchi reagents require accurate titration and tend to become cloudy on standing.

COMPARISON OF RESULTS OF GLOBULIN TESTS ON SPINAL FLUIDS WITH THE NOGUCHI REAGENTS AND WITH 3 PER CENT. POTASSIUM DIHYDROGEN PHOSPHATE ACETIC ACID

* Floccules smaller than in Noguchi test.

SUMMARY

A suitable reagent for the globulin test in spinal fluid may be prepared by dissolving 3 gm. of anhydrous potassium dihydrogen phosphate in 100 c.c. of distilled water and adding 0.05 c.c. of glacial acetic acid. In making the test, 0.2 c.c. of the spinal fluid plus 0.6 c.c. of the reagent are mixed in a small agglutination tube and placed in boiling water for six minutes. This test is slightly less delicate than the Noguchi test, but offers some advantages over the latter for field work.

Pathology of Schoolchildren.—In the school year 1917-1918, 21,263 children were examined, and of this number only 6,243 were reported to be normal, and 15,020 to be subnormal, or approximately 75 per cent. of the total number; 4 per cent. were found to be suffering from malnutrition, 5 per cent. from enlarged cervical glands, 15 per cent. with defective vision, 3.5 per cent. defective nasal breathing, 5.5 per cent. with defective teeth, 8.5 per cent. with enlarged tonsils, 1.25 per cent. with impediment of speech. These conditions exist in every community.—*Public Health News*, New Jersey.

HOSPITAL SERVICE IN RURAL COMMUNITIES

A PRELIMINARY REPORT

Prepared by Ernst C. Meyer, Director of the Department of Surveys and Exhibits of the Rockefeller Foundation International Health Board

New York

(*Continued from page 1223*)

PART II. PRESENT CARE OF SICKNESS

A Comparison of Medical Service Available in the United States and in Europe.—As the care of the sick is dependent largely on physicians, it is of interest to inquire into the availability of medical service. Facts set forth in Table 8 show that the United States in 1910 had three times as many physicians in proportion to the population as the most favored nations in Europe. This larger number may have been needed years ago when the population of the country was extremely scattered; but as the population becomes more dense, the necessity for the same proportionate number of physicians decreases.

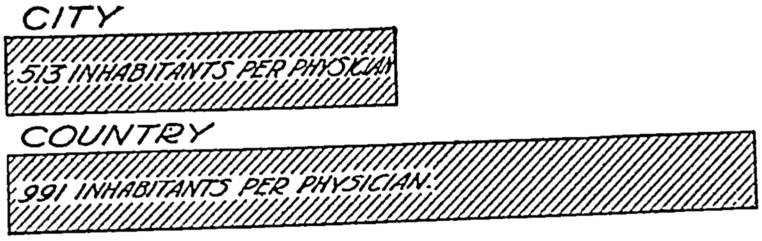

Fig. 4.—A comparison of medical service available in city and in country.

Since 1850, the output of physicians from the medical schools was rapidly increased, so that between 1900 and 1906 inclusive, the annual output exceeded 5,000. The largest number was graduated in 1904, the number in that year being 5,747. Since 1906, as a result of the improved standards of preliminary education and the merging of two or more medical schools in various cities by which in every instance one stronger and better equipped college resulted, a rapid diminution in the number of medical schools has occurred. And the annual number of graduates was likewise decreased, until in 1918 it was but 2,807. While this represents a decrease in quantity, it represents a marked improvement in the qualifications of the physicians graduated. It is quite evident that a physician who is competent to administer efficient treatment promptly is able to care for a larger number of patients than one who is not so well trained. That the United States is still abundantly supplied with physicians, if properly distributed, is evident from the fact that in 1918 there was one physician to every 712 people, or more than twice the number reported for the most favored countries of Europe.

More Service by Fewer Physicians than Formerly.—Contrary to widespread opinion, it seems that in proportion to the population the number of physicians has scarcely grown at all. Whereas the population increased about 138 per cent. from 1870 to 1910, the number of physicians increased about 153 per cent. Whereas in 1850 there were 569 people to one physician, in 1910 there were 582.

While difficult to measure, but highly gratifying to record, there undoubtedly has been a very large increase in the need and demand for medical aid during this period. This includes in particular:

1. Better care of chronic diseases, such as tuberculosis.
2. Increased care in childbirth.
3. Increased demand for purposes of laboratory diagnosis.
4. Increased work for public health inspection and control, as, for instance, medical school inspection and quarantine work.
5. Increase in teaching work and medical investigation.
6. Increase in routine laboratory work.
7. Large development of medical journalism.
8. Increased demand for insurance work.
9. Greater interest in health on the part of the public.

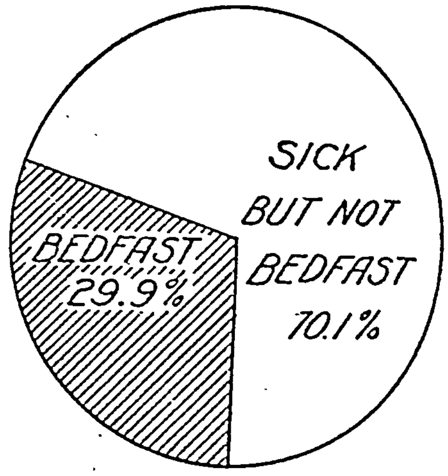

Fig. 5.—Number of bedfast among the sick.

There can be little doubt that the rate of increase in the supply of medical men has failed to measure up to the rate of increase in the demand for medical service. This development is, however, not to be deprecated, but to be welcomed. From the point of view of the general public conditions in the medical profession have been far from satisfactory. The quantity of medical service has been more than offset by its poor quality. With the improvement of medical education, the reduction of the number of graduates, and an increase in the intelligent demand for medical service, the conviction is felt that the quality of that service will continue to improve rapidly.

TABLE 8.—PROPORTION OF PHYSICIANS TO POPULATION IN VARIOUS COUNTRIES

Country	Year	Population per One Physician
United States	1910	582
Austria	1906	2,319
France	1911	1,969
German Empire	1910	2,124
Italy	1911	1,484
England and Wales	1911	1,537
Ireland	1911	1,943
Scotland	1911	1,175
Russian Empire	1912	7,865

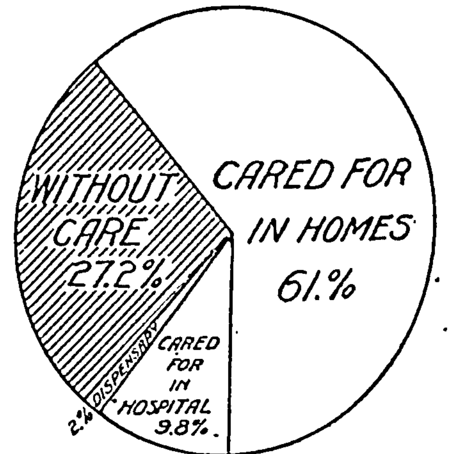

Fig. 6.—How 13,132 cases of sickness were found to be cared for (Metropolitan Life Survey).

Less Medical Service in the Country than in Cities.—Medical service, as expressed by the number of physicians available to render it, is far less accessible in the country than in the city. In fact, the country has only about half as many physicians to a given population as does the city.

In cities of more than 2,500 population there is one physician on an average for every 513 people, whereas in rural regions there is but one physician for every 991 people (Fig. 4). The figures quoted in Table 9 tend to overemphasize the situation, in that many physicians who have an extended country practice undoubtedly live in cities of more than 2,500. But even after allowance for this has been made, the statistics presented fail to express adequately the wide discrepancy between medical service available in urban and in rural communities. The density of population in cities, and the greater speed of communication and transportation enable city physicians to render much larger service in a given time than can be rendered in the country, where many hours are at times consumed on a single call.

TABLE 9.—RELATIVE NUMBER OF PHYSICIANS IN CITY AND COUNTRY

Population Group	Population	Number of Physicians	Population per One Physician
All cities over 2,500...........	46,921,963	91,797	513
Under 2,500 and rural.......	53,476,355	53,431	991

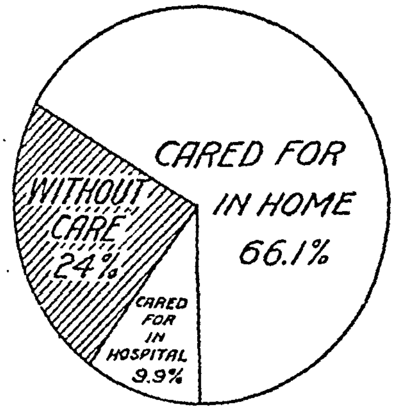

Fig. 7.—How 1,600 cases of sickness were found to be cared for (State Charities Aid Survey).

With the advent of the automobile, improved roads, interurban street car lines, the telephone, and other means of prompt intercommunication, one physician in the rural districts can now care for many times the number that were formerly cared for. Furthermore, country patients now in large numbers go to the city, where they receive treatment by city physicians and in city hospitals.

The different sections of the United States are supplied in a widely variant manner, as is evident from Table 10.

TABLE 10.—SUPPLY OF PHYSICIANS IN VARIOUS SECTIONS OF THE UNITED STATES

Division	Population per One Physician in Communities of: 25,000 and Over	10,000 to 25,000	5,000 to 10,000	2,500 to 5,000	Under 2,500	Total
New England............	594	695	741	723	713	649
Middle Atlantic..........	621	686	614	548	1,037	702
East North Central......	511	513	474	407	940	633
West North Central.....	454	484	424	366	914	668
South Atlantic...........	405	454	381	350	1,212	792
East South Central......	418	421	352	313	987	760
West South Central.....	461	445	368	317	933	735
Mountain................	440	444	489	455	1,040	711
Pacific....................	466	523	384	364	1,060	599

The rural South has the poorest medical service. The states of the Mountain and Pacific divisions come next, with the middle Atlantic states, New York, New Jersey and Pennsylvania, fourth. It is also of interest that in the South opportunities for medical service in all of the cities are larger than in the North. This may be due to the fact that physicians very largely locate in cities, particularly in those with a population of more than 2,500, and practice in the surrounding country regions. To the extent to which this is true, larger medical service is being given in rural regions than the figures would seem to indicate. In any event, it seems that the cities of the South have a more abundant supply of physicians than those of the North.

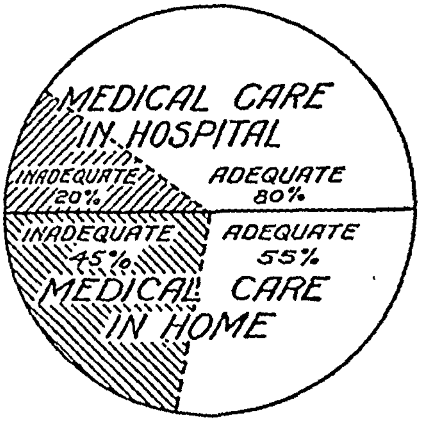

Fig. 8.—The large proportion of the sick who are inadequately cared for.

The country regions, it is believed, are further handicapped in medical service by virtue of the fact that physicians in practice there are older, and probably on the whole less up-to-date and efficient in their methods, than in the cities. Whereas, in 1910, 67.2 per cent. of the physicians in the forty-two largest cities were under 45 years of age, only 59.93 per cent. of those in communities of less than 50,000 population were under that age.

What the rural regions appear to need most is not a greater number of physicians but more wise and extensive use of the medical facilities which both country and city at present offer. These regions also need to develop a keener appreciation of the value of the public health nurse and of the full-time health officer. The development of efficient public health administration, better distribution in certain areas of private practicing physicians, harmonious cooperation between public and private health service, and intelligent demand for medical service—these are the things toward which the open country must strive.

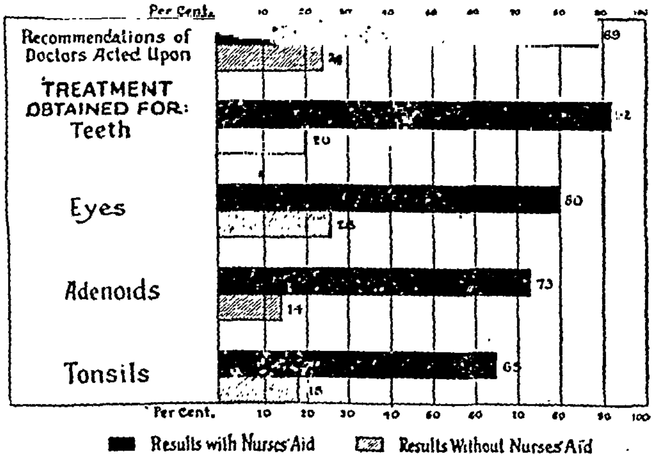

Fig. 9.—How follow-up work by nurses increases the value of the physician's advice. (Through the courtesy of Dr. Thomas D. Wood, Teachers College, Columbia University.)

HOSPITAL FACILITIES IN THE UNITED STATES

No study has ever been made of hospital facilities in the United States. Practically the only information covering the country that is available is found in the United States Bureau of the Census Report of 1910, in which a section is devoted to hospitals and sanatoriums. A summary of the information therein contained is given in Table 11.

In a rough sort of way this table may be a measure of hospital facilities available in various parts of the country. It was not possible to secure information as to the extent to which the urban centers might be favored in the matter of hospital service.

TABLE 11.—HOSPITAL FACILITIES

Division	Number of Persons Treated per 100,000 Population	Number of Persons For Every Hospital and Sanatorium	Number of Persons Population per Physician
New England states	6,023	28,244	564
Middle Atlantic states	3,564	38,631	619
Pacific states	2,911	36,775	435
Mountain states	2,405	23,725	537
East North Central states	2,163	48,028	576
West North Central states	1,554	45,461	573
South Atlantic states	1,293	63,186	795
West South Central states	844	125,493	608
East South Central states	568	135,644	690

THE NUMBER OF THOSE SICK IN BED

The various sickness surveys already referred to showed that about one out of every three sick persons was bedfast. It is important, however, to understand that the Metropolitan Life Insurance Company in its surveys classed all people who because of sickness were actually in bed, either at home or in hospital, as "bedfast" (Fig. 5).

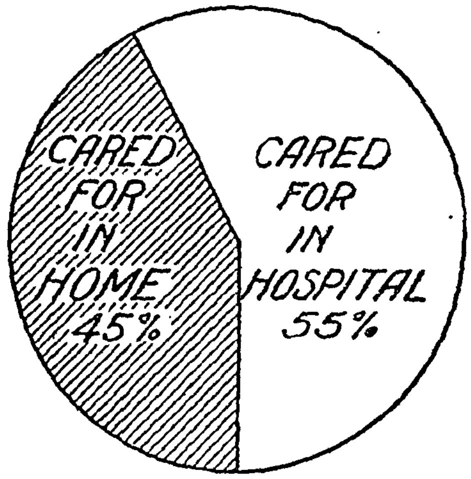

Fig. 10.—How cases of typhoid were found to be cared for.

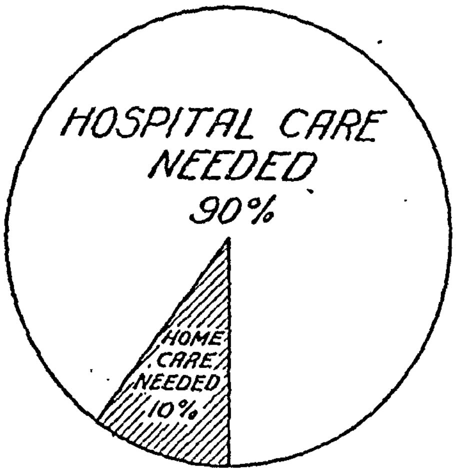

Fig. 11.—How cases of typhoid should have been cared for.

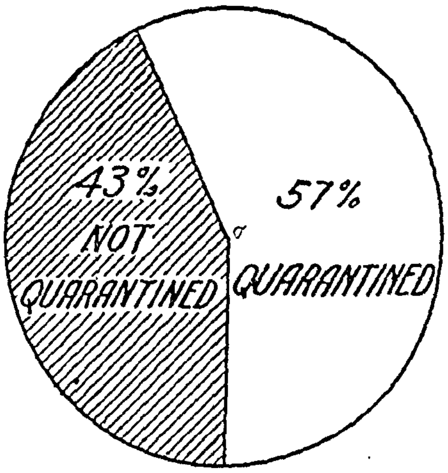

Fig. 12.—The large proportion of cases of measles that were not quarantined.

The bedfast constitute a distinctive sick problem. They are generally a heavy drain on the time, energy and resources of those on whom they are dependent. For many of the bedfast the logical place of treatment is the home, for others the hospital. It has been established that a considerable proportion of the bedfast are inadequately cared for, but definite statistical and other data are lacking as to the degree to which hospital care should be given beyond what is being done now.

TABLE 12.—PROPORTION OF BEDFAST

Area	Total Sick	Bedfast Number	Bedfast Per Cent.
Boston	1,902	326	17.1
Pittsburgh	1,869*	472	25.3
Rochester	798	220	27.6
Chelsea	356	129	36.2
Kansas City	862	279	32.4
North Carolina	1,881	537	28.4
Pennsylvania and West Virginia	7,333	2,437	33.1
Total	13,132	3,928	29.9

* The Pittsburgh total is included also in the figures for Pennsylvania and West Virginia.

Table 12 summarizes the findings in the sickness surveys within the areas indicated:

ADEQUACY OF MEDICAL CARE

It would seem from such information as is available that a large proportion of the sick, no matter where found, whether in country or city, received no medical care whatever. Out of 13,132 specific cases of sickness covered by the surveys of the Metropolitan Life Insurance Company, 4,411 had no medical care whatever. Among the total numbers of cases of sickness there were 11,975 classed as disabled, that is, the sick were unable to work. Of the latter group no less than 27.2 per cent. had no medical care. This undoubtedly was due more to failure to call a physician than to a lack of physicians. It was also noted that a large percentage of the medical care given was inadequate. This also was probably due more to failure on the part of the patient to call a physician or to having him call with sufficient frequency than to a lack of physicians. A relatively small number of those cared for, 9.8 per cent., were cared for in a hospital. The rest were either *not* cared for or were cared for in the home (Fig. 6). Table 13 presents details.

Of a further group of 1,600 cases, nearly 400, or one quarter of all those who needed medical care, had none. This was probably due more to the common neglect to call a physician, or to poverty, or to a possible lack of confidence in physicians, than to a shortage of the supply of physicians. Only a small proportion of the sick were cared for in hospitals (Fig. 7).

TABLE 13.—MEDICAL CARE OF THE DISABLED

Area	Disabled	Not Cared for	Cared for No.	Cared for %	Nature of Care Hospital No.	Hospital %	Home No.	Home %	Dispensary No.	Dispensary %
Boston	1,747	442	1,305	74.7	336	25.7	816	62.5	153	11.7
Rochester	661	239	422	63.8	85	20.1	337	79.8		
Chelsea	331	76	255	77.0	56	22.0	166	65.0	33	12.9
Kansas City	816	252*	564	69.1	45	8.0	512	90.7	7	1.2
Pittsburgh	1,791	418	1,373	76.7	200	14.6	1,164	84.8	9	0.6
Pa. and W. Va.	6,908	1,725	5,183	75.0	601	11.6	4,527	87.5	55	1.0
North Carolina	1,512	519	993	65.7	46	4.6	917	95.3		
Total†	11,975	3,253	8,722	72.83	1,169	13.4‡	7,305	83.63	218	2.81

* Other figures for Kansas City refer to sick; not to disabled.

† Excluding Pittsburgh.

‡ The percentage given in this table for cases of sickness cared for in hospital (13.4) is based on the number cared for. Figure 6 includes both the disabled cared for and not cared for; the percentage of hospital care therein shown (9.8) necessarily was based on the total number of disabled; hence the apparent discrepancy.

Table 14 presents the statistical details of the care of the 1,600 cases of sickness referred to above.

INADEQUACY OF CARE

The 1,600 cases of sickness already referred to were studied with a view to determining the adequacy or inadequacy of medical care received. By "adequate" care was understood care which resulted in the patient's recovery when recovery could be expected, and which was of such a character that neither the patient nor the community incurred avoidable risks. Unfortunately, four out of every ten of the sick did not get the sort of care they needed. It was found that almost half of those cared for in the homes, and 20 per cent. of those cared for in hospitals, were inadequately cared for (Fig. 8).

TABLE 14.—CARE IN ONE THOUSAND SIX HUNDRED CASES OF SICKNESS

Cases	Number	Per Cent.
In homes	1,058	66.1
In hospitals	159*	9.9
Without medical care	383	24.0
Total	1,600	100.0

* Includes fifty-eight cases cared for in hospital and home.

The inadequacy of hospital care was due chiefly to lack of social service and follow-up work. The importance of follow-up work in securing results in connection with medical care is strikingly illustrated in Fig. 9. The statistics on which it is based were gathered in connection with the medical inspection of school children. The principle, however, would seem to apply also to adults (Fig. 9).

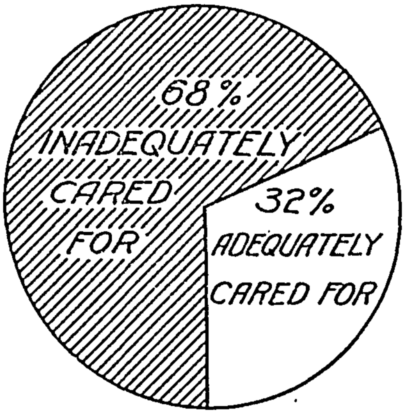

Fig. 13.—The large proportion of cases of measles that were inadequately cared for.

In many cases, patients returned to homes unprepared for them, so that, lacking adequate care, proper convalescence was impossible. In case of home care, poverty, lack of proper surroundings, ignorant attendance, and insufficient medical attention were largely responsible for the inadequacy of care received. In some cases people did not know how to secure good service, or good service was not available in every instance.

TABLE 15.—PROPORTION OF HOSPITAL AND HOME CARE NEEDED

Proper Place for Medical Care	Number of Cases	Per Cent.
In hospitals	442	28.0
In homes	1,158	72.0
Total	1,600	100.0

A few concrete illustrations will serve to emphasize the point. Out of twenty-nine cases of typhoid fever, 45 per cent. received home care, and 55 per cent. were cared for in hospitals (Fig. 10). It was thought that at least 90 per cent. of these cases should have had hospital care, and but 10 per cent. could safely be given home care (Fig. 11).

A further condition which threatened the health of the community was discovered in the treatment of measles. Of 176 cases, 57 per cent. were quarantined, and 43 per cent. were not quarantined. Fifty-three of the seventy-six cases not quarantined were under medical care (Fig. 12). It was found that but 32 per cent. of the 176 cases had adequate care; the rest had inadequate care (Fig. 13). The significance of this situation becomes still further apparent when it is known that these cases represented 2,835 days of sickness, and a loss of 917 school days on the part of seventy-four children of school age.

Similar lessons might be drawn from the conditions found to surround the care of malaria, scarlet fever, whooping cough, diphtheria, grip, chickenpox, tuberculosis and other diseases.

CARE RECEIVED AND CARE REQUIRED

Only about one third of the 1,600 sick who needed hospital care received it. In actual numbers, 159 had such care, whereas 442 were thought to require it. The lack of medical care, as already emphasized, was undoubtedly due more to inability to pay a physician or to neglect to call him than to a scarcity in the supply of doctors. Of those who had no care whatever, the majority could have been cared for in the home, whereas others should have been removed to a hospital (Fig. 14). Table 15 presents the statistical details on this point.

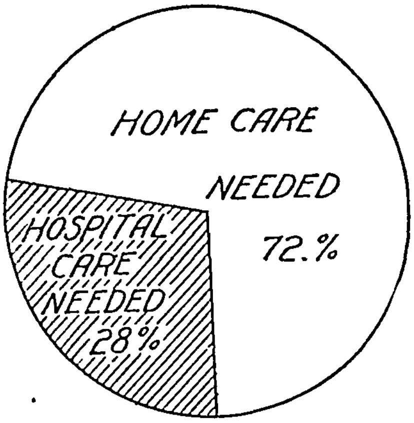

Fig. 14.—The proportion of hospital and home care needed by 1,600 cases of sickness.

Back to School.—In a bulletin of the Children's Bureau on the day's work and the empty schoolhouse, attention is called to the fact that the compulsory school attendance law does not protect the children as it should from the evils of long hours in industry and in the fields in agriculaural work. In the administration of this law, although many officers do their best to enforce the law, there are still many loopholes through which children may be piped to work, keeping them from the schools where they belong. The status of school terms and requirements as to attendance are thus set forth: In ten states the period of attendance is below five months. In Alabama, children must attend school for eighty days, and even this short term may be reduced to sixty days; in Florida, the attendance required is eighty days; in Georgia, four months; in Mississippi, sixty days, but the school board may reduce this to forty days; in North Carolina, four months; in South Carolina, four months in agricultural districts for child laborers; in Tennessee outside of cities of 5,000 scholastic population, eighty days, or entire session if this is less than eighty days; in Texas, 100 days, or entire session if less than 100 days; in Utah outside of first and second class cities, twenty weeks; in Virginia, sixteen weeks. Delaware has a required attendance of five months, which may be changed by vote to three. In three of the states mentioned, Florida, Mississippi and South Carolina, even the short term noted is not a statewide requirement.

SOME DETAILS OF PHOSPHORUS METABOLISM

For many years, diverse compounds containing phosphorus have been made topics of special emphasis in relation to medical problems. The highly toxic element phosphorus has been reputed to be a "nerve stimulant" and "reconstructive tonic." Some of its salts can produce no better recommendation than the vague claim of being "tonics." Sodium phosphate has an independent part as a saline cathartic, which is not associated with the previously mentioned medicinal virtues. Organic phosphorus compounds, notably the complex fat derivatives like lecithin, have been charged with exerting specially desirable effects in the direction of nutrition. One reads that they favor constructive metabolism in the body.

It is conspicuously true that complex phosphorus compounds are found widely distributed in the organism, where they unquestionably exert important functions and have specialized uses. It is not without significance, we presume, that phosphatids like lecithin and kephalin are found in practically every cell, or that they occur in such exceptional abundance in the nervous tissues. The production by the mammary gland of the unique phosphorized protein casein is another instance of "phosphorus specialization" in the animal economy. How do such unquestionably desirable compounds arise? Are they constructed out of preformed organic phosphorus-containing groups which are ingested as such, or can they be manufactured de novo from the simpler inorganic phosphorus derivatives? If the production of phosphorized brain cell and lipoids and the chief protein of the mammary secretion is dependent on special organic phosphorized precursors, obviously it becomes of prime necessity to supply these in the diet and in sufficient abundance.

The period of lactation represents a time when the demands for the structures out of which the specific phosphorus compounds of milk are built are particularly augmented. In an elaborate study on phosphorus metabolism as related to mammary secretion, Meigs[1] and his associates in the Dairy Division of the Bureau of Animal Industry have confirmed the conviction already warranted by other investigations in relation to the form in which phosphorus compounds enter the circulation for distribution to the places of need. Normal plasma contains no phosphorized proteins, and probably no phosphorus compounds at all except phosphatids and inorganic phosphates. The phosphorus of these two classes of compounds certainly comprises more than 97 per cent. of all that exists in normal plasma.

Although the concentration of phosphatid and of inorganic phosphorus in this fluid is highly variable, and both can be made to vary by changing the quantity of phosphorus supplied with the ration, one gains the impression, in harmony with observations of Greenwald,[2] that it is the inorganic fraction chiefly that is influenced in this way. In fact, the more recent researches on digestion and absorptions all point to the probability, to quote Meigs, that phosphorus from the digestive tract reaches the general circulation only in the form of inorganic phosphate, that all organic phosphorus compounds are synthesized within the body cells, and that phosphorized proteins are not transported at all by the plasma from one fixed cell in the body to another. If this conclusion is accepted, the special value of widely advertised organic phosphorus compounds alleged to present the element in some form unusually suited for assimilation disappears; for the digestive processes seem to dissolve all ties of complexity and present to the organism for absorption the uniformly simple ions of inorganic phosphates. This contention has long been supported by the Council on Pharmacy and Chemistry in forming an estimate of the claims of unique therapeutic potency ascribed to preparations of organically bound phosphorus, such as lecithins, glycerophosphoric acid, phytin, nucleic acids, and phosphoproteins. Marshall,[3] who conducted investigations for the Council's Committee on Therapeutic Research, has likewise rejected the view that such organic compounds of phosphorus are absorbed and stored as such by the organism. As he points out, in cases in which the introduction of phosphorus is desired to attempt to facilitate the synthesis of organic phosphorus compounds in the body, the inorganic phosphates, such as abound in foods, are entirely suitable for the purpose.[4]

Accordingly, it must not be supposed that because phosphorus enters the circulation in such simple combinations it escapes further constructive changes. Numerous investigations have indicated that phosphatids can be built up somewhere in the body out of ordinary fats and inorganic phosphates. Bloor's well known studies on fat metabolism[5] make it highly probable that fat absorbed from the alimentary tract is soon converted largely, if not completely, into phosphatids of the lecithin type by the red corpuscles. These phosphatids can thus in turn become the sources of a supply of phosphorus to organs and tissues. Meigs and his co-workers believe, in fact, that many of the tissues and organs of the body, of which the mammary gland and the muscles are conspicuous examples, can receive their fat and phosphorus from the blood only in the form of phosphatid. According to their conception, both structures convert the phosphatid into fat and inorganic phosphate; they use the fat, in the one case, to supply the fat of milk, in the other, to burn and supply energy; and they return the inorganic phosphate largely or wholly to the blood. In all of these newer researches the phosphatids play an important physiologic part as forms of transport for fat and phosphorus, respectively; but there is no indication that the body is dependent on a ready-made supply of phosphatids in the diet to maintain such functions, any more than it requires lactose or casein as such in the food intake to insure a proper production of them in the mammary gland.

HEMOLYTIC STREPTOCOCCI AND THE TONSILS

Death following a variety of acute infections, like measles and scarlet fever, is at present believed to be due to a secondary invader, usually in the guise of a streptococcus, rather than to the primary etiologic agent. Numerous contributions to The Journal,[6] not to mention other sources of information, have indicated that hemolytic streptococci are widely present in the pharyngeal passages of healthy persons as well as in diseased throats. The incidence of these microorganisms has been reported as high as 82 per cent. in companies of healthy men who have been in army camps for months. During epidemics of measles and of influenza, hemolytic streptococci have been found in some camps in practically all of the throats bacteriologically examined.

The recent investigations of Pilot and Davis[7] at the Cook County Hospital in Chicago, following those of Nichols and Bryan[8] at the Walter Reed General Hospital of the Army in Washington, point to the tonsils as the principal foci of these hemolytic organisms, which are so commonly found in cultures taken from different parts of the mouth and throat. The evidence is in accord as to the predominance of the streptococci in the crypts of the tonsils; and it appears that the frequency of these bacteria is decidedly less in the throats of persons whose tonsils have been extirpated than in the throats of persons having normal tonsils.

As hemolytic streptococci commonly present in the crypts of the tonsils are probably the most important source of the streptococcic complications of various acute infectious diseases, and of terminal infections in the persons innocently harboring the micro-organisms, it is important to ascertain how the secondary infections from them arise. At any rate, it seems more reasonable, on the basis of the knowledge at present available, to charge the responsibility to the tonsil-borne bacteria rather than to an invasion of unusually virulent strains from outside the body. Outbreaks of disease due to the entrance of foreign virulent streptococci unquestionably do occur at times, as the epidemics of septic sore throat testify; but in general the streptococcic infections are presumably associated with preexistent foci, like the tonsils, which harbor the bacteria in the body. Pilot and Davis have thus summarized the possible factors responsible for the secondary streptococcus infections: The existing dormant organisms in the tonsils or throat may become enhanced in their virulence through symbiosis or in some unknown way by the primary virus (measles, scarlet fever, smallpox), or by the bacteria, such as *B. diphtheriae,* the pneumococcus or the influenza bacillus. They may become active through the diminution of the resistance of the local tissues of the respiratory passages. They may attain increased invasive powers through the lowering of the general resistance of the host overwhelmed by an acute or chronic toxemia. Probably all three factors are combined in certain diseases, though one factor often appears to be more important than the others. Thus, in acute respiratory and throat infections, streptococci seem to spread from the tonsillar crypts to the adjacent mucous surfaces, descend into the bronchi and lungs, and enter the blood stream from these tissues. In chronic diseases, on the other hand, the diminution of the resisting power of the blood may admit the streptococci directly into the circulating blood stream without any marked local changes in the throat.

According to the army bacteriologists, local antiseptic treatment of the tonsils has not given satisfactory results, obviously because the crypts cannot be reached effectively in the way that the surface of the organs can. As it was found that excision of the tonsils renders the throat free from the objectionable streptococci in most cases, this operation appears as the only thoroughgoing method of curing carriers. Whether excision of healthy tonsils is justifiable is clearly debatable. There can be no question, however, as to the importance of knowing where danger lurks, so that it can be met and averted with corresponding intelligence.

STANDARDS FOR GROWTH

The period of physical development of each individual is an era of the highest significance for his entire life. It represents a time when all manner of formative influences are brought to bear on a receptive organism: the years when the bodily background for future potentialities is being created. The forces that direct this development and make its progress possible are at least twofold: hereditary and environmental. The environmental forces include nutrition, work and play, and are in some measure controllable. If they cannot always alter the limitations set by inherited factors, they can nevertheless frequently prevent deteriorating influences from making any inroad on the growing individual or interfering with the best attainment of his developmental possibilities.

If we are to assist in any degree in facilitating a proper environment for the young, it obviously becomes essential to have some standards by which to judge the success of the undertaking. What shall be the index of successful or satisfactory nutrition and growth? In everyday life, primary emphasis is at present accorded to the body weight; for this is something measurable with accuracy, whereas the judgments formed by the appearance of the person under investigation have obvious psychologic limitations. Diagnosis almost always gains in accuracy when exact quantitative measurement can be substituted for the guesswork of subjective impressions. Ascertained facts thus supplant haphazard assumptions which vary with the experience and dependability of the observer. To know that a patient has actually lost or gained 15 pounds in weight is decidedly more helpful than to suspect that he is "looking somewhat thin."

Is body weight the best measure of satisfactory growth in children? Or is the determination of growth in height a better index? Can either or both of these factors be related to age in such a manner as to answer the question, What is the normal? These queries have frequently been raised and discussed. A recent critical review of selected data bearing on the subject has been prepared by Holt[1] of the Columbia University College of Physicians and Surgeons. His statistics show a wide variation in the relation of weight to age—the weight-age curve—among the European nations, all of which are represented in our present American population. With such wide variations as those noted both in foreign and in American boys, it is evident, Holt says, that weight for age is not of great importance in determining the nutrition of a child.

Holt's study shows, further, that the curves for height and age in a general way correspond to those of weight and age among the different groups in the United States and also among the foreign boys in their relation to each other, but the variations in the height-age curves are considerably narrower. As the growth impulse is essentially a hereditary factor, it can be understood why variations in height are so great. The tendency to grow often exerts itself even in the absence of adequate nutrition, so that increase in size may occur with stationary weight at times. It appears from Holt's data that a much more important relationship than weight to age or height to age as an indication of the state of the child's nutrition is that of the weight to height. This index of nutrition appears to be far more independent of nationality; but of course there must be actual increment in size as well as a proper proportionality between height and weight. The weight-height index fixes the child's status in nutrition; the annual increase in size indicates his progress. Deviations from the average may still be regarded as normal. For practical purposes Holt puts the permissible deviation at 10 per cent. The careful inspection by a good observer is by no means to be dispensed with in forming an estimate of good nutrition and growth; but it may advantageously be supplemented by the facts secured through anthropometry.

LIPOVACCINES

Prophylactic inoculation of great masses of people against infectious diseases, such as typhoid, cholera, dysentery, plague and possibly pneumonia, has for years been an ideal in the minds of many sanitarians, especially those who have been in contact with the populous but disease-ridden oriental countries where even simple methods of sanitation have encountered opposition. Inoculation itself, however, has met so many practical difficulties that it has remained largely an unattainable ideal. With the vaccines heretofore used, a relatively severe local and general reaction followed the inoculation; and while the health officer, by means of a variety of expedients, might send home his first dose of vaccine, it was quite another matter to induce the subjects to come back for more. Nor has this been true in dealing with unintelligent communities only.

Ferran, so far back as 1885, inoculated thousands against cholera in Spain; the work of Haffkine with plague in India is well known; Shiga inoculated against dysentery in Japan, and the more recent work of Lister in South Africa against pneumonia also seems successful. The most pronounced results have been obtained with typhoid-paratyphoid vaccines. The severity of the reactions, however, has been sufficient to make mass application unpopular and therefore impracticable in civilian work.

Perhaps the use of lipovaccines will do more to solve the problem than any other factor. Le Moignic and Pinoy were the first to substitute oils for the physiologic sodium chlorid solution previously used in making vaccines, and the advantages of the change were obvious. Bacterial toxins and even endotoxins, to a degree, are lipotropic; and the fact that their toxic effects are inhibited when they are injected simultaneously with lipoids and lipoid-rich tissues, such as brain substance, has been explained on this basis. The lipoid-oil vehicle of the vaccine serves, therefore, not only in delaying absorption but very probably in some directly neutralizing manner. Indeed, Le Moignic and Pinoy found that they could inject three and four times the dose of the usual saline vaccine at a single injection of the lipovaccine without undue reaction and achieve an immunity that was on a par with that obtained following repeated inoculations with ordinary vaccines. The fact that bacterial vaccines prepared in oil do not deteriorate is also of decided value when mass vaccination is under consideration.

A lipodysentery vaccine has already been produced at the Army Medical School, and recently Fennel prepared a lipopneumococcus vaccine which, because of the simplicity of inoculation, will perhaps supersede the method of inoculation recommended by Lister.

An interesting application has been made, too, by Bossan and Le Moignic[1] with a lipotuberculin. They find that such vaccines, containing either the complete suspension of tubercle bacilli or the filtered product of the dissolved material, are efficient as antigens and at the same time quite innocuous, so far as local and general reactions are concerned.

Of course, a number of technical problems have presented themselves in the mass production of these vaccines—matters of dosage and of the proper sterilization of oils, and the inclusion of efficient preservatives and antiseptics (all of our common agents are lipotropic and therefore of lessened bactericidal power in an oil menstruum), and their sale in interstate commerce has so far not been authorized by our government—but there seems little doubt that within a few years the use of lipovaccines will be of great assistance in prophylactic inoculation against a number of infectious diseases, a procedure which so far has been delayed because of the inherent toxicity of the available vaccines.

Habits and Health.—The greater proportion of people are born healthy and their way of living makes them sick. The people of America are only 50 per cent. efficient on account of ill health and disease. Apparently our population is 100,000,000; actually it is only 50,000,000. This is the result of wrong feeding, cranky immoderation, not enough air and sunshine; impure and insufficient water drinking; alcohol, caffein and nicotin addiction, and our awful and absurd use of drugs and patent medicines.—*Bulletin*, Indiana State Board of Health.

Current Comment

CANDY AND CALORIES

With the after-war return of the nation to its normal mode of living, there are evidences on all sides of a relaxation of the strenuousness of the program of conservation. Wheat, meat and sugar are no longer restricted in their distribution in the ways that the voluntary rationing schemes of last year demanded. It is reported that the candy manufacturers, who have been so severely hampered by the necessity of producing sugarless sweets, are preparing for an increase in their business in the near future. We are told that the people of this country are learning that "candy is as healthful as it is delicious," and that "candy has more calories per pound than any of what are regarded as the ordinary dishes served at meals in the American household." Even the low score of caramels with only 1,400 calories per pound exceeds all but corn and rice among the more familiar dietary components; while milk is left quite in the background with a mere 800 calories per quart. We have no quarrel with candy lovers or with manufacturers of delicious sweets. Sugar and nuts and fats which enter into common confections are usually as digestible as they are toothsome. Having succeeded in educating the American public in some degree to the real meaning of calories as measures of food fuel, our experts in nutrition are face to face with a new problem in popular education. The public must now be taught that food values are not expressed in calories alone any more than miles-per-gallon of gasoline are the sole criterion of automobile excellence. A properly selected diet represents the inclusion of many items, some of which are not to be evaluated primarily in terms of calories. Every one ought to appreciate, after the nation-wide propaganda for more milk, that the latter food represents nutrient virtues that put it into the cheap-at-any-price class. The green vegetables contribute factors to our diet that candy can scarcely imitate. Even raw meat proved to be a blessing to Stefánsson[1] with which the choicest "package goods" could not compete when his party was threatened with scurvy during their sojourn in the Arctic regions. It has been asserted that sugar and sweets, though valuable fuel foods, are dangerous for children unless the use of these articles is carefully controlled. Writing in the manual of the United States Food Administration, Dr. Ruth Wheeler[2] states of sweets: "Because of their flavor, it is only too easy to eat too much of them. They are likely to cause digestive disturbances, to take away the appetite for other more valuable foods if eaten at the wrong time, and therefore indirectly to cause anemia and bad teeth. Obviously, they are entirely unbalanced foods, supply only fuel and no building materials in any permanent sense of the word. They must, therefore, supplement and not replace other food. In moderation, as dessert after a good meal, they are in their proper place." This expresses the crux of the matter:

Everything in its place—including candy. To propose that even the most delicious confection shall replace bread and butter, fruits and vegetables, meat and milk, is preposterous. Let candy rest on its long won laurels.

SMITH, JONES ET AL.

An interesting incident occurred in the recent war as the result of a similarity of names. A physician received orders to report for duty; on arriving at his post he discovered that the order was intended for another man of the same name. He failed in an attempt to recover expenses for travel from the War Department, since it was shown that he had not even applied for a commission. Most interesting is a recent incident in the British Army which the *Medical Officer* entitles "The Mysterious Disappearance of Dr. Herbert Jones." It appears that one of the districts of England had been endeavoring to secure the release from the army of its medical health officer, Lieut.-Col. Herbert Jones. While familiarly known as Herbert Jones, this officer was entered in the archives of his local government board as J. H. Jones. The Joneses fill twenty-eight closely printed columns in the Army List; there were thirty-two H. Joneses and seventeen J. H. Joneses, and there was considerable difficulty in attempting to reach the Jones wanted. In its closing statement the *Medical Officer* says: "It is quite possible that an advertisement in this journal —(the *Medical Officer*)—might catch the eye of one who used to be much interested in public health matters." And then—like the familiar valve-handle wheeze—it adds: "As we go to press we learn that Colonel Jones has been found and has now resumed his civil duties."

EDUCATIONAL INTERRELATIONS WITH MEXICO

In his letter last week our Mexican correspondent referred to the good results of recent visits by parties of Americans to Mexico in the establishing of cordial commercial relations between the two countries. He intimates also that closer relations might exist in intellectual lines, a desire which is most commendable and doubtless shared by the intelligent people of both countries. The plan of exchanging university professors has not as yet been carried out with Mexico and not a great many Mexican students do undergraduate or postgraduate work in the United States. If Spanish were studied more extensively in the United States and English more widely in Mexico, it would develop a better understanding between the two nations. All of these things have been much talked about, as our correspondent points out, but thus far have remained only "beautiful projects." He makes a single exception—the Spanish Edition of The Journal—which he says is the only concrete thing yet realized. Its appeal, however, is mainly to the medical profession and this, our correspondent believes, does not influence sufficiently the ruling, governmental class. The means outlined by our correspondent by which a closer friendship and harmony may be developed between the United States and Mexico deserve careful consideration and definite action on our part. It is reported that already a New York capitalist has offered to donate several million dollars to found an American university in Mexico City provided the Mexican government favors the proposal and that certain conditions can be met. It is said also that President Carranza has heartily welcomed the idea and given assurance that the Mexican government will further the movement in every way possible. It has even been suggested that a loan of $100,000,000 to Mexico by the United States government, to be used in founding schools and colleges, would do much toward solving the so-called "Mexican problem." In times past the universities of this country have exchanged professors with the universities of Great Britain, France and other European countries. It is reported that America and France are planning an exchange of clinical assistants who will be trained in the methods of the other nation in medical practice, philosophy and scientific research. The circle for this exchange of teachers, students, clinical assistants, etc., should be widened so as to include our sister republics. In this way bonds of fellowship, understanding and harmony may be established between the countries of North, Central and South America.

TYPHOID VACCINATION NOT A SUBSTITUTE FOR SANITARY PRECAUTIONS

No one can question the high protective value of typhoid vaccination in the American army. The brilliant results reached are common knowledge. At the same time, the evidence from France reinforces what bacteriologists have suspected for some time—that typhoid vaccination does not afford a protection that is absolute. Massive doses of typhoid bacilli are plainly dangerous, even when ingested by well vaccinated individuals. As in certain other diseases, the sense of security imparted by typhoid vaccination has led some persons to disregard sanitary precautions which might otherwise have been taken. A little knowledge is a dangerous thing. The man who believes that he is protected against typhoid by vaccination may take chances in drinking water from contaminated sources that otherwise he would have avoided. A recent memorandum by the chief surgeon[1] of the American Expeditionary Forces, reprinted in the *Public Health Reports,* points out with much force the necessity for maintaining sanitary regulations for all military organizations, vaccinated as well as unvaccinated. One instance is given of a replacement unit of 248 men reaching England from Camp Cody with nearly 40 per cent. of the men suffering from typhoid. Investigation was thought to indicate that the men were exposed to infection by contaminated drinking water while en route to the port of embarkation in the United States. Other small but relatively severe epidemics have occurred in various units in France. In November, typhoid began to appear more extensively in the expeditionary forces. According to Soper,[2] from September 27 to February 13 there were 821 cases of typhoid and 190 of paratyphoid in the American Expeditionary Forces in France. Apparently a large portion of these were due to the drinking of

contaminated water during the fighting in the Argonne. The memorandum by Colonel McCaw, chief surgeon of the American Expeditionary Forces, points out the importance of water contamination and carrier infection in the spread of typhoid fever under the conditions prevailing in France. It is emphasized that vaccination should be regarded only as a partial protection, and should always be reinforced by sanitary measures. In a word, valuable as typhoid vaccination has proved to be, its efficiency does not warrant any relaxation of sanitary precautions. The relatively high resistance of the vaccinated human organism may be overwhelmed by massive doses of typhoid bacilli, and perhaps also by small doses under certain predisposing conditions that increase individual susceptibility in ways not wholly understood.

Association News

VICTORY MEETING

Reduced Fares for Victory Meeting of the American Medical Association, Atlantic City, N. J., June 9-13

The chairman of the Passenger Traffic Committee, Eastern Territory, U. S. Railroad Administration, Mr. C. M. Burt, advises that all special reduced fares have been discontinued, and the resumption of such reductions during the coming summer season is not contemplated. However, summer tourist rates will be in effect to Atlantic City, tickets being sold from May 15 to September 30 with final return limit Oct. 31, 1919. Round-trip fares from Chicago will be $49.02; from St. Louis, $57.96; and from other points round-trip fares will be constructed on the general basis of 90 per cent. of the double one-way fares to Atlantic City, except that if this makes less than double the one-way fare to Philadelphia, then the through fare to Atlantic City will be double the fare to Philadelphia. A similar announcement has also been received at THE JOURNAL office from Mr. W. J. Craig, chairman of the Southern Passenger Traffic Committee.

Those who are planning to go to Atlantic City for the Victory Meeting are urged to consult the local ticket agents at their home town for complete information regarding fares and stop-over privileges available for the trip. Fellows should not leave the determination of the route they desire to take until just before they are ready to start on the trip. The local ticket agents may have to obtain official instructions as well as special tickets from central points, and arrangements should be made in time so that these tickets may be purchased in time for the journey. These local ticket agents will be able to obtain information and advise you concerning circuit routes which may be available and which may permit making side trips in connection with the journey to or from Atlantic City.

Annual Meeting of the Board of Trustees

The annual meeting of the Board of Trustees was held at the Association headquarters, Feb. 7, 1919, all the members being present. The President-Elect and the Speaker of the House of Delegates were also in attendance.

The Editor and General Manager submitted a comprehensive and detailed report which was carefully considered by the board.

COMPLETION OF HEADQUARTERS BUILDING

In addition to much routine business, the board acted on the following matters, which are here reported because of their interest to the membership: The board appointed a committee to consider the advisability of completing the headquarters building, in accordance with plans already adopted. The necessity of providing room for properly housing the employees of the Association and taking care of our increased business, prompted the board to this action. The committee was directed to report back to the board in time so that the board may present this subject to the House of Delegates.

HOSPITAL STANDARDIZATION

The question of hospital standardization was taken under consideration, and as this subject has been especially studied by the Council on Medical Education, the board heard a report from that council on the subject. This report summarized is as follows: When the council was established in 1905, one of its first acts was to define a standard of medical education. This included a requirement that a year be spent as an intern in a hospital. The council found that the majority of the better equipped graduates were voluntarily serving as interns. However, it has constantly been interested in establishing better facilities for this internship, and to this end, has secured certain data concerning hospitals and similar institutions throughout the country. In 1912, the council submitted its first general questionnaire to the hospitals, and the information obtained was verified, so far as this was practical, by inspection of hospitals conducted along with medical schools. In 1914, the council published a provisional list of hospitals which were considered to be equipped in such a manner as to provide acceptable opportunities to their interns. At the annual conference of the council in February, 1915, a preliminary report of the standardization of hospitals was presented. Immediately following this report, a second general survey was undertaken and this was participated in by an advisory committee appointed by the state medical associations. Two of these state committees, those of New Jersey and Pennsylvania, systematically inspected the hospitals of those states, and considerable similar work was done by the committees of other states. A third survey of hospitals is now in progress, the work having been begun in April of last year. The council recommended that, in addition to the use of questionnaires and inspections by the state committees, it is advisable that the hospitals shall be visited and inspected by a representative of that body. The council feels assured that those hospitals which provide acceptable opportunities for intern service, at the same time render an acceptable service to the sick.

The Board of Trustees, being advised that certain members of the Board of Regents of the College of Surgeons were in session on that day, invited these regents to a conference on the standardization of hospitals, making this a special order of business for 3:30 in the afternoon. At that hour the following members of the Board of Regents of the American College of Surgeons went into conference with Board of Trustees: William J. Mayo, president of the College, Rochester, Minn.; Albert J. Ochsner, Chicago; George W. Crile, Cleveland; Frank F. Simpson, Pittsburgh, and Mr. John G. Bowman, director of the College of Surgeons. The director of the college, Mr. Bowman, stated that the plan being followed in connection with the work of standardizing hospitals was centered mainly on case records, clinical laboratories and staff organizations. He said that the work was being carried out by a personal inspection of the hospitals. Dr. William J. Mayo said that it was the desire of the college to bring about a sympathetic understanding and cooperation between that organization and the American Medical Association. He stated that the two organizations had much to gain from cooperation, and that duplication of work should be avoided. It was mutually agreed that Dr. Colwell and Mr. Bowman should keep in close touch with each other on all matters pertaining to hospital work. It was also arranged that another conference be held in Atlantic City at the time of the annual meeting of the American Medical Association and that representatives of other organizations interested in hospital standardization and development be invited to be present.

The question of social and health insurance was discussed in a general way by Drs. Phillips and Lambert.

ELECTION TO EDITORIAL STAFFS AND COUNCIL

The board elected to the editorial staff of the *Archives of Internal Medicine*, Dr. George Dock, St. Louis; to the editorial staff of the *American Journal of Diseases of Children*, Dr. L. Emmett Holt, New York, and Dr. H. F. Helmholz, vice Dr. Frank Churchill, resigned because of removal from Chicago; on the Council of Pharmacy and Chemistry, Drs. C. L. Alsberg, Washington, D. C., Henry Kraemer, Ann Arbor, Mich., and John Howland, Baltimore, each to serve for five years; and Dr. W. W. Palmer, New York, to fill the vacancy caused by the death of Dr. J. W. Long, for a term extending to 1922.

A JOURNAL OF SURGERY

The board decided to establish, as soon as practical, another special journal, on surgery.

PURCHASE OF LIBERTY BONDS

In compliance with the recommendations of the Finance Committee, the board directed the purchase of $30,000 of the Fourth Liberty Loan bonds and set aside $10,000 to be subscribed to the Fifth Victory Liberty Loan.

SECOND MEETING OF BOARD

The Board of Trustees next met on April 18, with all the members present, except Dr. Bert W. Ellis, who was unable to attend; there were also present the President, President-Elect and Speaker of the House of Delegates.

Dr. Phillips reported progress in arranging for the foreign delegates to the coming annual session. The committee of the board having this matter in charge were empowered to act in all matters pertaining to the details in arranging for the Victory meeting.

The board was advised that, according to the action taken at its February meeting, $30,000 of the Fourth Liberty Loan bonds had been purchased, making the total of $115,000 invested by the Association in the several Liberty Loans. On the suggestion of the General Manager, the board directed that a sufficient amount be subscribed to the Victory Liberty Loan so as to bring the total of holdings of the Association up to $150,000.

Medical Mobilization and the War

Personnel of the Medical Corps

For the week ending April 25, the Medical Corps contained 18,567 officers, a decrease of 178 from the previous week. The Medical Reserve Corps contained 1,687 officers. The total number of medical officers discharged since the beginning of the war is 19,378.

Wounded Severely

The following medical officer has been reported as having been wounded severely: James W. Duckworth, Lieut., M. C., U. S. Army, Martinsville, Ind.

Wounded, Degree Undetermined

The following medical officers have been wounded, degree undetermined: James R. Miller, Hartford, Conn., and Manuel G. Morales, Chicago, Lieutenants, M. C., U. S. Army.

Soldiers' Teeth Good

Reports collected by Captain Huber, divisional surgeon of the 88th Division at Gondrecourt, showed that less than half of the 26,437 men in the division needed dental treatment.

Wounded Slightly

The following medical officers have been reported as having been wounded slightly: Eric A. Abernethy, Chapel Hill, N. C.; Charles Lynn, New York; Lewis A. Moore, Monroe, Wis., and Ernest W. Slusher, Kansas City, Mo., Majors, M. C., U. S. Army; and Benedict Aron, Chicago; Valentine B. Eiler, Titusville, Pa.; Aaron T. Lukins, Pullman, Wash., and Barton B. McCluer, Bon Air, Va., Lieutenants, M. C., U. S. Army.

Blind and Maimed

It is reported from the Bureau of War Risk Insurance, April 10, that there are only 125 cases of total blindness and less than 4,000 amputations of the American Forces engaged in war. Not all of the cases of blindness are declared yet, as permanent. Despite rumors to the contrary, there have been no cases of amputation in which men lost both arms and both legs. More than 500 artificial limbs had been furnished up to April 10.

Weekly Bulletin, A. E. F.

(April 7, 1919)

This bulletin is devoted chiefly to extracts from a typical Weekly Health Bulletin issued by the chief surgeon of the Third Army. Most of the material concerns a report as to the occurrence of typhoid in the Third Army, and the remainder to statistics on venereal diseases with the number of cases coming from each town, when known. Attention is called to the fact that louse infestation still occurs among many of the men, and the advisability of close clipping of all of the body hair is to be seriously considered by the surgeon. It is noted that 10,071 members of the 28th Division were found infested with lice on arrival at Le Mans, all of whom have been disinsected. The weekly review indicates that there has been a decrease in all communicable diseases, except in meningitis and typhoid fever. For the month of March chickenpox, measles and the typhoid-paratyphoid fevers have increased, all other diseases decreasing.

Awards of Military Cross

The following medical officers have been awarded the British Military Cross by King George: Frank MacGregor, Temple, Texas; Harold E. Foster, Castile, N. Y., and James H. Keeling, Albany, N. Y., Captains, M. C., U. S. Army, and Burton Maltby, Liberty, Mo., Lieut., M. C., U. S. Army, and Roy A. Douglass, Huntingdon, Tenn.

Awarded Belgian Cross of War

Guy G. Giffen, Lieut., M. C., U. S. Army, Dayton, Ohio, has been decorated with the Belgian War Cross by King Albert.

Distinguished Service Cross

The following officers have been awarded the distinguished service cross by the commanding general, American Expeditionary Forces, for extraordinary heroism in action in Europe:

WILLIAM D. McLELLAND, first lieutenant, Medical Corps, 304th Sanitary Train. For extraordinary heroism in action near Nantillois and Montfaucon, France, September 29 to October 1, 1918. Lieut. McLelland near Nantillois, displayed untiring energy in bringing in the wounded while continually subjected to machine-gun and shrapnel fire. It was necessary to move the dressing station to some abandoned German dugouts because of the heavy fire, and during the bombardment this station was set on fire and six men killed, but Lieut. McLelland, by his coolness and courage, enabled the speedy evacuation of the wounded.

WILLIS H. KEENAN, first lieutenant, Medical Corps, 369th Infantry, Coshocton, O. For extraordinary heroism in action in the Champagne sector, France, Sept. 26-Oct. 1, 1918. Although suffering from illness, this officer remained on duty day and night throughout the engagement. When his battalion was in reserve, he voluntarily went forward to the assaulting battalions whose surgeons had been evacuated. In the attack on Sechault he exposed himself continuously to intense artillery and machine-gun fire while rendering first aid.

THOMAS EDWARD JONES, first lieutenant, Medical Corps, 368th Infantry. For extraordinary heroism in action near Binarville, France, Sept. 27, 1918. Lieut. Jones went into an open area subjected to direct machine-gun fire to care for a wounded soldier who was being carried by another officer. While dressing the wounded runner, a machine-gun bullet passed through his arms and chest and a man was killed within a few yards of him.

JOHN RAY, captain, Medical Corps, 119th Infantry, Raleigh, N. C. For extraordinary heroism in action near Bellicourt, France, Sept. 29, 1918. Establishing his first-aid station in the front line, he advanced with the infantry. He continued on with the troops, caring for the wounded, until he himself was so badly wounded that he was evacuated. He died from his wounds a few days later.

Distinguished Service Medal

General Pershing has awarded the Distinguished Service Medal to the following named medical officers:

FRANCIS A. WINTER, Brigadier-General, M. C., U. S. Army. As chief surgeon of the lines of communication, American Expeditionary Forces, from June to December, 1917, he organized medical units at the base ports and in camps in France. He established large supply depots from which medical supplies were distributed to the American Expeditionary Forces, and by keen foresight and administrative ability, made these supplies at all times available for our armies.

FRANK C. BAKER, Colonel, M. C., U. S. Army. As commanding officer of Evacuation Hospital No. 6, at Chateau-Thierry from June to August, 1918. Colonel Baker so promptly arranged his hospital under most difficult conditions, and, with great resourcefulness and good judgment, made such use of the inadequate means at his disposal that he was able to receive and evacuate after splendid treatment and in perfect order a large number of wounded from the Marne offensive at a time when that section of France was greatly demoralized.

JOSEPH A. BLAKE, Colonel, M. C., U. S. Army. As chief consultant for the district of Paris, and commanding officer of Red Cross Hospital, No. 2, he efficiently standardized surgical procedures especially in the recent methods of treating fractures. His remarkable talent has materially reduced the suffering and loss of life among our wounded.

GEORGE W. CRILE, Colonel, M. C., U. S. Army, Cleveland. By his skill, researches and discoveries, he saved the lives of many of our wounded soldiers. His tireless efforts to devise new methods of treatment to prevent infection and surgical shock revolutionized Army surgery and met with the greatest success.

GUY L. EDIE, Colonel, M. C., U. S. Army. He was placed in charge of the medical service at Brest at the time when it became the chief port of debarkation for American troops, and at a period when the arrival of tro[illegible] numbers, and with many sick, overwhelmed all [illegible] for their care. By his great resourcefulness he [illegible] the many difficult problems that were presented.

JOEL E. GOLDTHWAIT, Colonel, M. C., U. S. Army, Boston. As a member of the medical corps he has, by his unusual foresight and organizing ability, made it possible to reclaim for duty thousands of men suffering from physical defects. He has thereby materially conserved for combat service a great number of men who would have been lost to the service.

PAUL C. HUTTON, Colonel, M. C., U. S. Army. As chief surgeon of the Paris group from June 2 to July 26, 1918, during which period by his good judgment and untiring energy he provided a hospitalization and evacuation system that insured prompt and excellent care and treatment of the wounded. He furnished the means of saving many lives and provided comfort for the wounded, thereby greatly adding to the morale of the combatant troops of both the American and the French engaged in the second battle of the Marne.

PERCY L. JONES, Colonel, M. C., U. S. Army. He served with marked distinction as commander of the United States ambulance service with the French armies. By the force of his energy, zeal and ability, he brought the units of that service to a high state of perfection. The splendid record held by this service is attributable to his great devotion and untiring effort in accomplishing his tasks.

JAMES R. MOUNT, Colonel, M. C., U. S. Army. Arriving in France with the first American troops he undertook the task of creating a medical supply depot and administering a medical supply service for the American Expeditionary Forces. Using his limited resources with great skill and judgment he displayed unusual talent for organization and laid the foundation of an efficient medical supply service.

ERNEST L. RUFFNER, Colonel, M. C., U. S. Army. He served as surgeon of the intermediate section, services of supply, having under his supervision thirty-nine base hospital units. He performed his strenuous and exacting duties in an unusually efficient manner, displaying rare judgment and professional attainments of the first order.

THOMAS W. SALMON, Colonel, M. C., U. S. Army, New York City. He has, by his constant tireless and conscientious work, as well as by his unusual judgment, done much to conserve manpower for active front line work. He was the first to demonstrate that war neurosis could be treated in advanced sanitary units with greater success than in base hospitals.

ALEXANDER N. STARK, Colonel, M. C., U. S. Army. He served as chief surgeon of the 1st Army during all its offensives, charged with the organization and direction of the medical service, involving the treatment and evacuation of many thousands of sick and wounded under most adverse conditions. In this important capacity he performed his duties with marked ability. With good judgment, furthered by high professional attainments and tireless energy, he solved the difficult problems which arose, prevented much suffering and saved the lives of many among the American and French wounded soldiers.

SANFORD H. WADHAMS, Colonel, M. C., U. S. Army. In his capacity as assistant to the chief surgeon, American Expeditionary Forces, and, later as a member of the general staff, he ably supervised the hospitalization and evacuation activities of the medical corps in advanced areas. By his timely anticipation of requirements he assisted in a marked degree the support of our operations against the enemy.

WILLIAM H. WILMER, Colonel, M. C., U. S. Army, Washington, D. C. As surgeon in charge of medical research laboratories, air service, American Expeditionary Forces, since September, 1918, he has rendered most distinguished service. His thorough knowledge of the psychology of flying officers and the expert tests applied efficiently and intelligently under his direction have done much to decrease the number of accidents at the flying schools in France and have established standards and furnished indications which will be of inestimable value in all future work to determine the qualifications of pilots and observers. The data collected by him is an evidence of his ability, his painstaking care and of his thorough qualifications for the important work intrusted to him. The new methods, instruments and appliances devised under his direction for testing candidates for pilots and observers have attracted the attention and been the subject of enthusiastic comment by officers of the allied services, and will be one of great importance in promoting the safety and more rapid development of aerial navigation.

HENRY BEEUWKES, Lieut.-Col., M. C., U. S. Army. He rendered especially valuable services as inspector of hospitalization of troops in the field. By tireless energy in the performance of his duties he assisted greatly in raising the efficiency of this service and in bettering the facilities for the caring and evacuation of the wounded of our armies.

ERNEST G. BINGHAM, Colonel, M. C., U. S. Army. As chief surgeon of the Paris district he most efficiently directed the coordination of the work of the hospitals and hospital and ambulance trains in the region of the Paris group during the second battle of the Marne. By his untiring zeal and his exact understanding of conditions, he most ably handled the limited hospital resources of the District of Paris, permitting the clearing of the battlefield of the wounded and the proper provision for their care. In all these tasks he showed professional attainments of the highest order, unflagging energy and great devotion to duty.

FRED T. MURPHY, Colonel, M. C., U. S. Army, St. Louis. As director of base hospital No. 21, as supervisor of the evacuation of the sick and wounded of the First Army, and later as director of the bureau of medicine and surgery of the American Red Cross, he rendered most valuable assistance to the American Expeditionary Forces. Throughout his service he displayed unusual administrative ability and professional skill, combined with a genius for organization that contributed greatly to the efficiency of the medical service of the Army. Untiring in zeal and enthusiastic in his duty he was an inspiration to those associated with him.

BURTON J. LEE, Lieut.-Col., M. C., U. S. Army, New York City. As surgical consultant attached to the second division he served continuously at the front, organizing his forces for the treatment and evacuation of the casualties with skill and marked success. He displayed unusual ability in the operations before Soissons when in an emergency he organized, personally led, and directed surgical teams which cared for hundreds of wounded soldiers at a time when adequate hospitalization could not be established.

CHARLES H. PECK, Lieut.-Col., M. C., U. S. Army. As director of base hospital No. 15, which he had organized most efficiently, he displayed unusual skill and very marked ability in the conduct of that unit. Later as senior consultant in general surgery for the American Expeditionary Forces, his professional attainments, wide experience and sound advice proved of inestimable value in increasing the efficiency of the medical department of the United States Army.

ARNOLD D. TUTTLE, Colonel, M. C., U. S. Army. In his capacity as assistant to the chief surgeon, and later, as a member of the general staff, American Expeditionary Forces, he supervised the preparation of hospitalization plans and their execution, and assisted in the evacuation of sick and wounded from the battlefields in such manner as to greatly increase the efficiency of his department.

EMIL H. BURGHER, Major, M. C., U. S. Army. As regimental surgeon of the 138th infantry he supervised the care of the wounded during the Argonne offensive. With untiring energy and ability of a high order, displaying personal courage under shell fire, personally rallying his men and directing them forward, he was an inspiration to all. His dressing station was placed to within a few hundred yards of the front lines, whenever the terrain rendered the passage of ambulances impossible. His zeal, devotion to duty and efficient services added greatly to the morale of all who served with him.

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

Note.—In the following list L. signifies lieutenant; C., captain; M., major; L. C., lieutenant-colonel, and Col., colonel.

ORDERS TO OFFICERS OF THE MEDICAL CORPS, U. S. ARMY

Alabama

To Camp Gordon, Ga., base hospital, from Camp Dix, Major M. A. WATKINS, Birmingham.

To Fox Hills, N. Y., from Camp Dix, Major L. W. GROVE, Tuscaloosa.

The following order has been revoked: *To Camp Travis, Texas*, Lieut. W. W. ROWAN, Alabama City.

Arkansas

To Camp Pike, Ark., base hospital, from Fort Sam Houston, Capt. J. I. SCARBOROUGH, Little Rock.

To Hot Springs, Ark., from Camp Pike, Capt. F. L. CASTLEBERRY, Paragould.

California

To Camp Kearney, Calif., base hospital, from Camp Lee, Capt. T. J. BERGGREN, Coronado.

To report to the commanding general, Western Department, from San Francisco, Col. J. A. MURTAGH.

To Sacramento, Calif., Mather Field, from San Diego, Capt. P. de OBARRIO, San Francisco.

To San Francisco, Calif., Letterman General Hospital, from Camp Kearney, Capt. H. O. VON DER LEITH, San Francisco.

Colorado

To Denver, Colo., from Oteen, N. C., Capt. S. SIMON, Denver.

To Fort McHenry, Md., from Walter Reed General Hospital, Capt. W. A. McGUGAN, Denver.

To Spartanburg, S. C., from Oteen, N. C., Capt. G. H. CATTERMOLE, Denver.

District of Columbia

To Camp Lee, Va., base hospital, from Camp Dix, Lieut. A. M. MacDONALD, Washington.

To Fort Sam Houston, Texas, from Army Medical School, Col. E. B. VEDDER.

To Spartanburg, S. C., from Camp Meade, Lieut. C. B. COVEY, Washington.

Georgia

To Army Medical School, from Camp Gordon, Capt. S. B. GILLESPIE, Willacoochee.

To Camp Gordon, Ga., base hospital, from Fort McPherson, Major E. V. KELLER, Atlanta.

To Fort McPherson, Ga., from Camp Grant, Lieut. C. M. WEST, Atlanta.

Illinois

To Camp Gordon, Ga., base hospital, from Fort Oglethorpe, Lieut. W. H. MILLER, Chicago.

To Detroit, Mich., from Camp Custer, Capt. J. W. CLARK, Chicago.

To Fort Sheridan, Ill., from Camp Dix, Lieut. R. F. ELMER, Chicago.

To Fox Hills, N. Y., from Camp Dix, Capt. S. B. HERDMAN, Taylorville.

Indiana

To Camp Meade, Md., as orthopedic surgeon, from Camp Dix, Major C. C. CRUM, Jeffersonville.

To Denver, Colo., from Camp Taylor, Capt. H. B. COX, Morristown.

Kansas

To Camp Dix, N. J., base hospital, from Fort Benjamin Harrison, Major H. ATKINS, Pratt.

To Fort Sheridan, Ill., from Jefferson Barracks, Lieut. F. A. TRUMP, Ottawa.

To Pittsburgh, Pa., from Jefferson Barracks, Lieut. A. B. OECHSLI, Stockton.

Kentucky

To Camp Sevier, S. C., base hospital, from Jefferson Barracks, Lieut. J. T. MALONE, Jr., Louisville.

To Camp Zachary Taylor, Ky., base hospital, from Camp Dix, Capt. H. C. WOODARD, Louisville.

Louisiana

To Carlisle, Pa., from Fort Bliss, Major H. P. JONES, New Orleans.

To Washington, D. C., Surgeon-General's Office, from Camp Dodge, Lieut. K. W. KINNEY, New Orleans.

Maryland

To Camp Dix, N. J., from Plattsburg Barracks, Capt. M. LEVY, Baltimore.

To Camp Meade, Md., from Camp Dodge, Capt. O. H. McNEMAR, Odenton.

To Colonia, N. J., from Walter Reed General Hospital, Capt. H. P. MAUCK, Lieut. D. F. ELMENDORF, Baltimore.

To Walter Reed General Hospital, D. C., from Fort Ontario, Lieut. P. PEARLSTEIN, Baltimore; from Hoboken, Major G. A. STEWART, Baltimore.

The following order has been revoked: *To Fort McHenry, Md.*, from Camp Dix, Lieut. C. A. REIFSCHNEIDER, Baltimore.

Massachusetts

To Army Medical School, from Camp Meade, Major A. W. SELLARDS, Boston.

To Camp Dix, N. J., base hospital, from Eastview, Capt. H. E. CARNEY, Boston.

To Fox Hills, N. Y., from Camp Dix, Major T. W. HARMER, Boston.

The following order has been revoked: *To Camp Crane, Pa.*, from Hoboken, Lieut. G. A. BUCKLEY, Brockton.

Michigan

To Camp Dodge, Iowa, base hospital, from Camp Custer, Lieut. C. R. WALSH, Detroit.

To Camp Kearney, Calif., camp hospital, from Arcadia, Major H. S. BARTHOLOMEW, Lansing.

To Camp Upton, N. Y., base hospital, from West Baden, Capt. P. B. TAYLOR, Detroit.

To Fort Sheridan, Ill., from Camp Custer, Lieut. W. M. BURLING, Grand Rapids.

Minnesota

To Camp Dodge, Iowa, base hospital, from Rock Island, Ill., Major C. H. CLARK, Duluth.

To Fort Snelling, Minn., from Camp Dodge, Capt. F. M. MANSON, Worthington.

The following order has been revoked: *To report to the commanding general*, Southern Department, from San Antonio, Capt. J. C. WILKINSON, Red Lake Falls.

Missouri

To Camp Abraham Eustis, Va., camp hospital, from Pig Point, Va., Lieut. E. V. KRING, St. Louis.

To Camp Dodge, Iowa, as tuberculosis examiner, from Jefferson Barracks, Capt. F. C. ESSELBRUEGGE, St. Louis.

To Camp Zachary Taylor, Ky., from Jefferson Barracks, Capt. G. S. DRAKE, Lieut. J. L. HUTTON, St. Louis.

To Fort McPherson, Ga., from Fort Sill, Capt. T. J. LYNCH, St. Joseph.

To Fort Sheridan, Ill., from Jefferson Barracks, Capt. A. LEVY, St. Louis.

To Fox Hills, N. Y., from Williambridge, Capt. J. F. McFADDEN, St. Louis.

To St. Louis, Mo., from Jefferson Barracks, Lieut. H. J. BLOUNT, Potosi.

Montana

The following order has been revoked: *To Hot Springs, N. C.*, from Camp Zachary Taylor, Lieut. J. E. ARNOLD, Miles City.

New Jersey

The following order has been revoked: *To Camp Zachary Taylor, Ky.*, base hospital, from Camp Dix, Capt. T. S. McCABE, Newark.

New York

To Camp Dix, N. J., as orthopedic surgeon, from Army Medical School, Lieut. C. A. LEE, Brooklyn. *To examine the command* for nervous and mental diseases, from Camp Meade, Lieut. C. E. TUBB, Poughkeepsie.

To Camp Sherman, Ohio, to examine the command for cardiovascular diseases, from Jefferson Barracks, Lieut. C. SHOOKHOFF, Brooklyn.

To Eastview, N. J., from Fort Riley, Capt. W. P. BLISS, New York City.

To Fort Ontario, N. Y., from Syracuse, Capt. E. J. WYNKOOP, Syracuse.

To Fort Schuyler, N. Y., from Camp Grant, Major S. S. PIPER, Elmira.

To Fort Sheridan, Ill., from Jefferson Barracks, Lieut. N. W. GETMAN, Oneonta.

To Fort Snelling, Minn., from Camp Dix, Capt. T. H. SWEETSER, New York.

To Fox Hills, N. Y., from Camp Dix, Capt. W. G. DORAN, New York; from Williamsbridge, Capt. L. E. GRIMBERG, New York.

To Hoboken, N. J., from New York City, Major L. K. GRAVES, Elmhurst; from Surgeon-General's Office, Lieut. R. MALCOLM, Yonkers.

To Lakewood, N. J., from Camp Dix, Lieut. N. M. DINGMAN, New York.

To Otisville, N. Y., from Oteen, N. C., Lieut. W. G. HAYWARD, Jamestown.

To Washington, D. C., Surgeon-General's Office, from Hoboken, Lieut.-Col. C. H. YOUNG, New York.

The following order has been revoked: *To Camp Upton, N. Y.*, base hospital, from Camp Dix, Capt. J. J. PARSONS, Cortland.

North Carolina

To Oteen, N. C., from Otisville, Capt. J. R. WILLIAMS, Asheville.

To Pittsburgh, Pa., from Camp Polk, Capt. E. M. BARNES, Raleigh.

To Spartanburg, S. C., from Camp Gordon, Capt. C. C. ORR, Asheville; from Camp Upton, Capt. C. S. JORDAN, Asheville.

To Walter Reed General Hospital, D. C., from Camp Greene, Lieut. J. J. MOORE.

Ohio

To Camp Zachary Taylor, Ky., base hospital, from Jefferson Barracks, Lieut. R. L. KUNKLE, Piqua.

To Fort Riley, base hospital, from Camp Cody, Capt. W. F. MILLHON, Columbus.

To Fox Hills, N. Y., from Williamsbridge, Lieut. G. H. REEVE, Cleveland.

To Rantoul, Ill., from Hampton, Va., Lieut. J. W. CAINES, Cuyahoga Falls.

To report to the commanding general, Philippine Department, from Camp A. A. Humphreys, Capt. H. S. HAYES, Whitehouse.

To Spartanburg, S. C., from Oteen, N. C., Lieut. A. M. ROSENBLUM, Youngstown.

To Walter Reed General Hospital, D. C., from Philadelphia, Capt. A. CROTTI, Columbus; from Surgeon-General's Office, Major P. D. WILSON, Columbus.

Oklahoma

To Mineola, N. Y., Hazelhurst Field, from Fort Reno, Capt. W. W. D. AKERS, Tyrone.

Oregon

The following order has been revoked: *To Camp Lewis, Wash.*, Lieut. B. R. BROOKE, Portland.

Pennsylvania

To Camp Dix, N. J., to examine the command for nervous and mental diseases, from Lakewood, Lieut. C. E. CASE, Philadelphia.

To Otisville, N. Y., from Camp Abraham Eustis, Lieut. H. P. BLAKE, Walston.

To Pittsburgh, Pa., from Washington, D. C., Lieut. T. F. MOORE, Pittsburgh.

Rhode Island

To Camp Devens, Mass., from Panama Canal, Major G. W. GARDNER, Providence.

To Fox Hills, N. Y., from Camp Dix, Capt. C. A. FARRELL, Westerly.

South Carolina

To report to the commanding general, Eastern Department, from Charleston, Col. T. J. KIRKPATRICK, Jr.

South Dakota

To Fort Des Moines, Iowa, from Camp Dix, Capt. G. G. COTTAM, Sioux Falls.

To Fort Sheridan, Ill., from Fort Oglethorpe, Lieut. N. J. NESSA, Sioux Falls.

Tennessee

To Camp Lee, Va., base hospital, from Colonia, Lieut. C. W. ROBINSON, Memphis.

To Camp Zachary Taylor, Ky., from Camp Shelby, Capt. J. H. McCALL, Huntington.

Texas

To Camp Meade, Md., from Camp Dix, Major W. H. LLOYD, El Paso.

To Camp Travis, Texas, from Camp Zachary Taylor, Lieut. A. D. WAGES, Waco.

To Fort McPherson, Ga., from Fort Worth, Lieut. R. WRIGHT, New Braunfels.

To Fort Sam Houston, Texas, base hospital, from Camp Dix, Major W. F. McMANUS, San Antonio; from Fort McHenry, Capt. M. W. SHERWOOD, Temple.

To Mineola, N. Y., from Houston, Major J. DIBBLE.

To Washington, D. C., Surgeon-General's Office, from Houston, Lieut. H. M. ANDREW.

The following orders have been revoked: *To Camp Meade, Md.*, from Camp Dix, Major J. G. FLYNN, Galveston. *To report to the commanding general*, Southern Department, from Houston, Lieut. D. H. BROOK, Travis.

Utah

To Fort Douglas, Utah, from Camp Lewis, Capt. H. C. JORGENSON, Salt Lake City.

Vermont

The following order has been revoked: *To Camp Sheridan, Ala.*, base hospital, from Camp Dix, Lieut. J. D. THOMAS, Pownal.

Virginia

To Fort Porter, N. Y., from Fort Ontario, Lieut. G. G. HANKINS, Phoebus.

Wisconsin

To Walter Reed General Hospital, D. C., from Fort Ontario, Capt. W. T. KRADWELL, Wauwatosa.

The following order has been revoked: *To Lake Charles, La.*, from Montgomery, Ala., Capt. H. S. STEENBERG, Milwaukee.

Wyoming

To Walter Reed General Hospital, D. C., for instruction, and on completion *to his proper station*, from Jefferson Barracks, Capt. O. P. HAMILTON, Sheridan.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Laboratory Donated.—Dr. Russell M. Cunningham, Birmingham, has donated to the Jefferson County Medical Society his large medical library, which has been installed in the medical section of the public library in the city hall.

Power Company Surgeons Meet.—Surgeons employed by the Alabama Power Company held their annual meeting in Birmingham, April 14, under the presidency of Dr. Benjamin B. Simms, Talladega. About forty members were present at the meeting.

Personal.—Dr. F. Marion Inge, Mobile, was elected president of the World War Veterans at the meeting held in Mobile, April 14.——Dr. Andrew M. Stovall, Jasper, was rescued from drowning in the Mobile River by Capt. Edward Roberts, who has been recommended by the Medical Association of the State of Alabama to receive a Carnegie Medal.

State Association Meeting.—The fifty-second annual session of the Medical Association of the state of Alabama was held in Mobile, April 15, 16 and 17. As Dr. Isaac L. Watkins, Montgomery, the president, was unable to preside because of sickness, Dr. William F. Betts, Evergreen, the first vice president, presided, assisted by Dr. Henry S. Ward, the second vice president. The meeting was a very interesting one and was in the nature of a victory meeting, and most of the papers were by men who had seen military service. A service flag was unfurled commemorating the 603 Alabama doctors (out of a total of 2,400 in the state) who accepted commissions in the Army and Navy. Six gold stars adorned the flag. Proper exercises were held to welcome the returned and to commemorate the dead. Lieut.-Col. James Somerville McLester, Birmingham, who was consultant to the medical staff at Brest, was elected president, and Dr. Walter Stratton Britt, Eufaula, vice president. The association had as its distinguished out-of-state visitors Drs. Joseph Colt Bloodgood, Baltimore, and George W. Crile, Cleveland. The next meeting will be held on the third Tuesday in April, 1920, at Anniston.

CALIFORNIA

Physicians' Licenses Revoked.—On March 21 the California State Board of Medical Examiners revoked the licenses held by Dr. J. Ottis Burnette and Dr. George H. Richardson, both of Los Angeles, on charges of having performed illegal operations.

Chiropractic Bill Twice Defeated.—A bill providing for a separate board for the licensing of chiropractors was defeated in the California legislature on March 26 by vote of 39 to 38. It was reconsidered on April 2 and again defeated, this time by a vote of 42 to 32.

Correction.—The notice of the death of Roy Oliver Thompson, which appeared in The Journal of April 19, page 1175, was incorrect. Dr. Thompson states, and The Journal is glad to announce, that he had a mild attack of influenza in March, 1919, but made a good recovery. Our report of the death of Dr. Thompson was based on a notice which appeared in the Los Angeles *Times*, which was sent to The Journal by the *California State Journal of Medicine*.

Draft Board Members Organize.—Physicians who have served on boards of the selective draft met in Santa Barbara, April 17, and took the preliminary steps toward forming a national organization, the plans of which will be perfected at the meeting of the American Medical Association in June. Dr. Henry P. Newman, San Diego, was selected as president of the association, and Dr. Paul E. Simonds, Riverside, as secretary.

Personal.—Dr. LaVerne C. Wright, Oakland, has returned after nearly a year of Red Cross work in France.——Dr. Henry O. Eversole, Los Angeles, heads the group of Red Cross workers on the British hospital ship, *Madras*, which is carrying the first contingent of Czechs from Vladivostok to Trieste.——Dr. Luther M. Powers has been reappointed health commissioner of Los Angeles.——Dr. Thomas B. W. Leland, Lieut.-Com. M. C., U. S. Navy, San Francisco, has been discharged from the Navy and has resumed his duties as coroner of San Francisco.

State Society Meeting.—At the annual meeting of the Medical Society of the State of California held in Santa Barbara, April 15-17, under the presidency of Dr. Cornelius Van Zwaluwenburg, Riverside, the following officers were elected: president, Dr. Henry A. L. Ryfkogel, San Francisco; vice presidents, Drs. Henry G. Brainerd, Los Angeles, Dudly A. Smith, Oakland; secretary, Dr. Saxton T. Pope, San Francisco (reelected); delegate to the American Medical Association, Dr. Alfred B. Spalding, San Francisco, and councilors, Drs. William H. Kiger, Los Angeles, James H. Parkinson, Sacramento, and Oliver D. Hamlin, Oakland. Del Monte was selected as the next place of meeting

Illegal Practitioners Arrested.—A Portuguese, named Gonsales A. Da Horta, according to a report from Fresno, was arrested on March 28 for practicing medicine without a license. He was released on $200 bail.——A news report from San Francisco states that Dr. Samuel P. Blumenberg was arrested on March 4 on a charge of having performed an illegal operation on a young woman which is said to have caused her death.——An Oakland report states that three Chinese, Fong Wan, Chen Law Sing and Lai King, were arrested by the state medical board for practicing medicine without licenses. They have been released on bail of $300 each.——Dr. T. Leung, a Chinese herbist of Los Angeles, was arrested by the state medical board, according to report, for violating the medical practice act. He was released on bail of $1,500.——Seven Japanese physicians, R. Haruki G. Suzuki, T. G. Nacayama, B. Nakaraha, T. H. Hayashi, John Doe Watanobi and John Doe Ochiai, according to a report from San Francisco, were arrested several months ago on charges of falsifying their examination papers before the state board of medical examiners. The state board discovered that the interpreter who assisted them with their examination papers was making a business of such practice. Bail in each case was fixed at $3,000.

GEORGIA

Long's Portrait Presented to Infirmary.—Dr. Joseph Jacobs recently presented to the Crawford Long Infirmary, on the campus of the University of Georgia, Augusta, a life size portrait of the late Dr. Crawford W. Long, discoverer of surgical anesthesia.

Control of Cancer.—A meeting was held in Atlanta, April 15, at which a campaign was initiated which will be waged by the medical men and club women of the state against malignant disease. Jarrett W. Palmer, president of the Medical Association of Georgia, presided, and the chief address was made by Frederick L. Hoffman, statistician for the Prudential Insurance Company.

State Association Meeting.—At the seventeenth annual session, held in Atlanta, April 16, 17 and 18, 1919, under the presidency of Dr. Jarrett W. Palmer, Ailey, the following officers were elected for the ensuing year: president, Dr. Edward G. Jones, Atlanta; vice presidents, Drs. William H. Hendricks, Tifton, and James M. Smith, Valdosta; secretary-treasurer, Dr. William C. Lyle, Augusta; delegate to the American Medical Association, Dr. Allen H. Bunce, Atlanta; alternate, Dr. Eugene E. Murphy, Augusta. Macon was selected as the place of meeting in 1920.

New County Officers.—At a meeting, April 15, held in Metter, the Candler County Medical Association was organized with Dr. Wallace D. Kennedy, Metter, president, and Dr. Buford B. Jones, Metter, secretary-treasurer.——Murray County Medical Society at its annual meeting at Chatsworth, March 3, elected Dr. Robert H. Bradley, president; Dr. Emmet H. Dickie, vice president, both of Chatsworth, and Dr. James E. Bradford, Spring Place, secretary.——Sumter County Medical Association, at its annual meeting, April 10, at Americus, elected Dr. Taylor Lewis, president; Dr. William S. Prather, vice president, and Dr. Joseph T. Stukes, secretary-treasurer, all of Americus.

ILLINOIS

New Officers.—At the annual meeting of the McLean County Medical Society, held in Bloomington, April 8, Dr. Watson W. Gailey, Jr., Bloomington, was elected president; Dr. Lyford M. Johnson, Arrowsmith, vice president, and Dr. A. Bernice Curry, Bloomington, secretary-treasurer.

Sanatorium to Be Constructed.—It has been decided to locate the DeKalb County Tuberculosis Sanatorium on the Marsh property between DeKalb and Sycamore on a site of 25 acres, which has been purchased for $16,000. The construction of the new institution will begin this summer.

Smallpox in Illinois.—In Kane and DuPage counties it is estimated that there are approximately 400 cases of smallpox. In Aurora alone there are said to be 74 cases. Kane County is reported as having 85 cases, Peoria County 62, Tazewell County 60 cases, Montgomery and Vermilion counties each 20, Madison County 18, and McLean County 15 cases.

Want Representation on Committee.—The Illinois State Medical Society, through its council, on April 16, adopted a resolution setting forth the provision of the civil administrative code for an advisory committee for the registered nurses, consisting of five persons, each of whom is a registered nurse in the state of Illinois, and setting forth further that the medical profession is chiefly concerned in the education, training and employment of nurses, and recommending the enactment into law, of Senate Bill No. 123, and House Bill No. 175, which bills provide for an equitable representation on this committee.

Health Promotion.—The work of organizing Illinois cities for the appropriate observance of health promotion week, from May 11 to 17, is already under way, backed by the enthusiastic support of Governor Lowden, Dr. C. St. Clair Drake, director of the state department of health, Springfield, and Walter D. Thurber, executive secretary of the Illinois Tuberculosis Association. The program includes a general clean-up, the eradication of breeding places for flies and mosquitoes, the holding of special exercises in schools and churches, the staging of community pageants and better baby conferences, and the exploitation of the various activities of the state and local health departments.

Illegal Practitioner Fined.—Arthur Earl Baker of 1212 South Adams Street, Peoria, was arrested by an inspector for the department of registration and education of the state of Illinois and fined $166 for practicing medicine without a license and for violating the pharmacy law. Arthur Earl Baker is the son of the late Dr. R. W. Baker of Peoria, who was a licensed physician in Illinois. Since the death of his father, Arthur Earl Baker has been practicing in Peoria on his father's license. Some years ago he made application for a license to the state authorities, but did not report for an examination. He has kept his father's name on his office door and has answered calls for "Dr. Baker." The son secured a narcotic license from the federal authorities in the name of his father in 1917, and used it in connection with writing prescriptions for, and dispensing narcotics to, his patients. The state authorities turned Baker over to the federal narcotic officials, and his case has been taken up with the Department of Justice at Washington.——Stefan W. Sobolewski of 1111 Marshfield Avenue, Chicago, was arrested by the Department of Registration and Education of the State of Illinois and fined $50 and costs for practicing medicine without a license.——Dr. William F. Bohannon of Peoria was also arrested and fined $25 on the same charge.

Chicago

New Hospital.—This month work will be begun on the addition to the Ravenswood Hospital at North Winchester and Wilson avenues.——A maternity hospital will be erected by the associated catholic charities in celebration of the seventy-fifth year of the creation of the catholic archdiocese of Chicago. The building will cost $100,000 and will accommodate 100 patients.

Violation of Drug Law.—Charged with having sold large quantities of morphin sulphate without a license, in violation of the Harrison Antinarcotic Law, Dr. Frank C. Howard is said to have been arrested, April 24, and held to the grand jury under bonds of $5.000.——George E. Thraites, colored, was arrested, April 16, charged with selling morphin to addicts and is held under bonds of $5,000.

Exchange of Clinical Assistants.—At a joint session of the Chicago Medical Society and Chicago Surgical Society, April 23, a plan was announced for the exchange of clinical assistants by surgeons and physicians of France and the United States. Major Dehelley of the French army opened the subject, and Dr. A. J. Ochsner, Chicago, stated that he had made arrangements for the exchange of clinical assistants with a French surgeon.

Personal.—William H. G. Logan, Col., D. C., U. S. Army, has returned after several months spent in France.——Dean D. Lewis, Lieut.-Col., M. C., U. S. Army, director of Base Hospital No. 13, at Limoges, France, for ten months, has been assigned to special duties at Fort Sheridan, Ill.——Maurice L. Blatt, Major, M. C., U. S. Army, has returned from military service and resumed practice.——Daniel L. Eisendrath, Capt., M. C., U. S. Army, has been released from military service and resumed practice, April 21.——Samuel J. Walker, Major, A. R. C., has been decorated by King Alexander of Greece, for valuable service rendered in relief work.

MARYLAND

Personal.—Dr. William H. Welch of Baltimore has been awarded the gold medal of the National Institute of Social Sciences. The presentation was made formally, in absentia, at the annual dinner of the institute on April 25 by Mr. Theodore Marburg. Dr. Welch is now abroad attending the Red Cross conference at Cannes, France.——Col. George Walker, Baltimore, of the American Expeditionary Forces and a member of the staff of the Johns Hopkins Hospital, is now attending the conference at Cannes, called by the committee of the Red Cross societies, which convened April 1.——Lieut.-Col. Lewis J. Rosenthal of Baltimore has returned home after twenty-three months' service overseas.——Major Alexander D. McConachie of Baltimore has arrived with Base Hospital Unit No. 202, from Brest, and is now with this unit at Camp Merrit, N. J.

Meeting of the Medical and Chirurgical Faculty.—At the one hundred and twenty-first annual meeting of the Medical and Chirurgical Faculty of Maryland, held April 22, 23 and 24, the following officers were elected to assume office Jan. 1, 1920: president, Dr. James E. Deets, Clarksburg; vice presidents, Drs. Arthur M. Shipley, Thomas R. Boggs and E. F. Jones; secretary, Dr. John Staige Davis (reelected); treasurer, Dr. Charles E. Brack; delegate to the American Medical Association, Dr. Randolph Winslow, Baltimore, and alternate, Dr. Lewellys F. Barker, Baltimore. An interesting program was given on the evening of the 24th, military night, when Major-Gen. Merritte W. Ireland, Surgeon-General of the U. S. Army, addressed the meeting and discussed the war problems that his department had met. He was followed by Brig.-Gen. Francis A. Winter, commandant of the Army Medical School, who told of the work of the medical department in the line of communication of the American Expeditionary Forces. Recent developments of war surgery were discussed by Brig.-Gen. John M. T. Finney, Baltimore, who did notable work abroad, while Brig.-Gen. William S. Thayer, Baltimore, described his observations on the practice of medicine in connection with the American Expeditionary Forces. A notable incident at the opening of the sessions was the sending of a cablegram to Sir William Osler at Oxford, England, felicitating him on the approach of his seventieth birthday. Dr. Osler was a former president and ardent worker for the faculty. The final session was devoted to clinics at U. S. Army General Hospital No. 2, Fort McHenry.

NEBRASKA

New Hospital.—The bill in legislature providing for the erection of a hospital at the Soldiers and Sailors Home, Milford, at a cost of $100,000, has been recommended for passage.

Roentgenologists Meet.—The annual meeting of the Omaha Roentgen-Ray Society was held in Omaha, April 5, under the presidency of Dr. Anders P. Overgaard, Omaha. About 300 were in attendance and in addition to the program of papers, roentgen-ray clinics were held at St. Joseph's Hospital by Dr. Albert F. Tyler, Omaha, and at the University of Nebraska Hospital by Dr. Carl H. Ballard, Omaha. The evening session was devoted to the hearing of experiences from members who had served abroad.

Personal.—Dr. Charles Rosewater, Omaha, who has been seriously ill with pleurisy is convalescent.——Robert D. Schrock, major, M. C., U. S. Army, Omaha, one of the pioneer American surgeons in army service in France, has returned and is on duty at the Post-Graduate Hospital, New York City, in the orthopedic service.——Dr. Frederick A. Sedlacek, Omaha, has started for Siberia as a member of the Red Cross unit.——Dr. John H. Morrow, Merna, who underwent operation in an Omaha hospital recently for appendicitis, is reported to be in a serious condition.

NEW HAMPSHIRE

Personal.—Russell Wilkins, Major, M. C., U. S. Army, Concord, who is now on duty in France with the twenty-Sixth Division, has been promoted to lieutenant-colonel, M. C.——Dr. John H. Neal has been elected city physician and a member of the board of health of Portsmouth.

Hillsborough County Physicians Meet.—At the annual meeting of the Hillsborough County Medical Association, April 15, Charles E. Congdon, Major, M. C., U. S. Army, Nashua, at present in service in France, was elected president; Dr. Clarence O. Coburn, Manchester, vice president, and Dr. Timothy F. Rock, Nashua, secretary-treasurer (reelected).

NEW YORK

Personal.—Dr. W. T. Barger, Katonah, has gone to Vladivostok, Siberia, in the service of the American Red Cross.

State Society Meeting.—The one hundred and thirteenth annual meeting of the Medical Society of the State of New York will be held May 6 to 8, in Syracuse, under the presidency of Dr. Thomas H. Halsted, Syracuse.

New York City

Efficiency and Sanitation.—The address before the New York Academy of Medicine at its stated meeting, May 1, was delivered by Col. John R. Murlin, U. S. Army, on "Efficiency and Sanitation in the Feeding of the United States Army."

Personal.—Dr. Foster H. Kennedy, Keeneyville, N. Y., late major in the Royal Army Medical Corps, British Expeditionary Forces, has returned to this city and resumed his practice.——Dr. James T. Pilcher has been mustered out of service with the United States Army and has resumed his practice in Brooklyn.——Dr. John L. Baker, Brooklyn, has been elected first vice president of the Fulton Street Board of Trade.

State Narcotic Commission Begins Work.—The New York City branch of the state narcotic commission has opened offices in the Health Department Building and announces that narcotic clinics will be opened in this city and throughout the state, one having already been opened at Albany. The New York City health department will not open any more drug clinics, but will continue the work of the clinic recently established at 145 Worth Street. In the short time that this clinic has been in operation it has treated 3,931 patients, an average of 700 a day.

NORTH CAROLINA

Boards of Trustees Consolidated.—At the recent session of the legislature, the special boards of trustees for the different state hospitals were abolished and a single board of eleven members was created. Of these, two are clergymen, two editors, one woman, and a banker and five business men. No physicians were appointed on the board. At its meeting for organization at Raleigh, Joseph G. Brown, Raleigh, was elected chairman, and R. R. Clark, Statesville, secretary.

State Hospital Association Meeting.—The annual meeting of the North Carolina State Hospital Association was held in Pinehurst, April 6, under the presidency of Dr. Jacob F. Highsmith, Fayetteville. An earnest effort is being made by the organization to standardize the hospitals of the state and their schools for training. The following officers were elected: president, Dr. John P. Munroe, Charlotte; vice presidents, Drs. J. T. Burrus, High Point, and Elijah T. Dickinson, Wilson, and secretary-treasurer, Dr. John Myers, Charlotte.

State Board Salaries.—At the annual business meeting of the state board of health the payment of salaries on the following basis was arranged: secretary, $5,000; director of hygiene laboratory, $4,000, with an increase of $50 each year, up to a salary not to exceed $4,500; chiefs of bureaus, expending less than $25,000, a salary of $2,500, with an increase of $50 each year, to a maximum salary of $3,000; and chiefs of bureaus expending over $25,000, a salary of $3,000, with an increase of $50 for acceptable services, up to a maximum of $3,500.

State Society Meeting.—The sixty-sixth annual session of the Medical Society of the State of North Carolina was held at Pinehurst, April 15 to 17, under the presidency of Dr. Cyrus Thompson, Jacksonville, the subject of whose address was "Art of Living." It was decided to hold the next meeting at Charlotte, and the following officers were elected: president, Dr. Carl V. Reynolds, Asheville; vice presidents, Drs. Herbert D. Walker, Elizabeth City, F. Stanly Whitaker, Kingston, and Thomas I. Fox, Franklinville; secretary-treasurer, Dr. Benjamin K. Hays, Oxford, and delegates to the American Medical Association, Dr. Chase P. Ambler, Asheville, and Hubert A. Royster, Raleigh

Personal.—William L. Dunn, Lieut.-Col., M. C., U. S. Army, Asheville, has returned from service overseas, and resumed practice.——Dr. Percy Ahrons, Raleigh, has been elected health officer of Wake County.——Charles O'H. Laughinghouse, Lieut.-Col., M. C., U. S. Army, Greenville, who recently returned to the United States, was presented with a gold hunting case watch, by members of his Base Hospital Unit No. 85.——John T. Burrus, Lieut.-Col., M. C., U. S. Army, High Point, who commanded a base hospital at Camp Beauregard, La., has returned home.——Drs. Cyrus Thompson, Jacksonville, and Fletcher R. Harris, Henderson, have been reelected members of the state board of health for terms of six years.

Health Officers Meeting.—The ninth annual session of the North Carolina State Health Officers Association was held in Pinehurst, April 14, under the presidency of Dr. J. Rufus McCracken, Waynesville, whose address was on "What the State Is Doing for Its Unfortunate." Dr. James A. Keiger, U. S. P. H. S., spoke on the venereal disease work, and Dr. Watson S. Rankin, Raleigh, secretary of the state board of health, reviewed the "Control of Diphtheria." The afternoon session was held in the Eureka Farm Life School, and at the evening session Charles O'H. Laughinghouse, Lieut.-Col., M. C., U. S. Army, Greenville, spoke on overseas observation of public health. Dr. Everett F. Long, Lexington, was elected president; Dr. Carl V. Reynolds, Asheville, vice president, and Dr. George M. Cooper, Raleigh, was reelected treasurer.

PENNSYLVANIA

Personal.—Dr. George K. Strode, Harrisburg, has been appointed assistant chief health inspector of the department of health of Pennsylvania.

Osteopath Bill Defeated.—The Goehrings bill giving osteopathic practitioners the same authority in hospitals as medical men was defeated in the house, April 22, 126 by 23.

Quarantine Laws to Be Revised.—Dr. Edward Martin, state commissioner of health, proposes sweeping changes in the present quarantine laws. General revision of the quarantine laws will be introduced in the legislature during the coming week. Defects in the present laws were apparent during the recent influenza epidemic and the proposed act offers a means of preventing a reoccurrence of such conditions as occurred in Pittsburgh and Lancaster last fall. The new act will give the department of health the needed authority to cope with all contagion, as considerably more power is vested in the commissioner and the advisory board. There will also be a drastic act making it a misdemeanor to transmit social diseases and the health authorities will be given permission to send to detention hospital chronic carriers of such disease. Endorsement is also given to a bill prohibiting publication of advertisements of venereal disease cures.

Philadelphia

Personal.—Lieut.-Col. William E. Ashton, M. R. C., who served with the Three Hundred and Ninth Field Artillery through all the operations of the first army, has returned and is at Camp Dix awaiting discharge.——Major Henry C. Earnshaw, M. R. C., who served twenty-two months in the Army, first with Base Hospital No. 10 and then with American Sixth Army Corps as a medical consultant, has returned to his home in Bryn Mawr.

TENNESSEE

Donation to Meharry College.—The Carnegie Foundation and the general education board of the Methodist Church have each offered a gift of $150,000 to the Meharry Medical College, Nashville, conditioned on the raising of an additional $200,000 by the Freedmen's Aid Society of the Methodist Episcopal Church and the trustees and friends of the college, the latter fund to be used for endowment only.

Personal.—Perry C. Wilkes, for several years superintendent of the Baptist Memorial Hospital, Memphis, has been promoted to chief manager of the institution, and Sidney G. Davidson of the Good Samaritan Hospital, Philadelphia, has been appointed his successor.——Dr. William E. McCampbell, Nashville, was seriously injured when his automobile was overturned, March 20. He sustained fracture of the clavicle and of several ribs.

State Association Meeting.—The eighty-sixth annual meeting of the Tennessee State Medical Association was held in Nashville, April 8 to 10, under the presidency of Dr. Richmond McKinney, Memphis, and the following officers were elected: president, Dr. Andrew F. Richards, Sparta; vice presidents, Drs. Julius C. Brooks, Chattanooga, Nicholas S. Walker, Dyersburg, and Albert W. Harris, Nashville; secretary, Olin West, Nashville, reelected, and treasurer, Dr. Joseph F. H. Gallagher, Nashville reelected. Chattanooga was named as the next place of meeting.

Hospital Items.—The county court of Madison County at an adjourning session, April 13, appropriated $1,000 for the maintenance of a civic league hospital, Jackson, the city giving a like amount.——Excavation work has commenced on the Methodist Hospital, Memphis, which is to be erected at a cost of $350,000. The corner stone will probably be laid late in May.——Giles County is about to issue $25,000 in bonds to secure money with which to build a hospital in the county as a memorial to the men who served in the European war.——An addition is to be built to the Baptist Memorial Hospital, Memphis, to cost about $250,000. This addition will house a nurses' training school and home.——The new Protestant Hospital, Nashville, was opened to receive patients, March 22. The institution has been built at a cost of $250,000 and will accommodate 100 patients.

CANADA

Osteopath Bill Rejected.—The bill the osteopaths submitted, or intended to be submitted to the Quebec legislature, did not reach that body, for it was thrown out in committee. The medical profession took the stand that osteopaths should qualify under the same conditions necessary for all specialists to obtain legal recognition.

Association News.—The eighth annual meeting of the Canadian Public Health Association will be held in Toronto, May 26 to 28, and it will be a joint congress with the Association of the Officers of Health in Ontario.——The annual meeting of the Canadian Medical Association will be held in Quebec City, June 25 to 27. Dr. Jasper Halpenny, Winnipeg, will deliver the address in surgery.

Hospital News.—A home for the deaf and dumb has been decided on by the Manitoba government. The cost will be $500,000, and it will be located in Winnipeg.——Saskatchewan will shortly commence the erection of another hospital for the insane in the southern part of the province. The cost will be $250,000, and $155,000 has also been set apart for additional buildings at the existing hospital for the insane at Battleford.——The total cost of the sanatorium to be built by the dominion government and the government of Alberta near Calgary will be $460,000, of which the dominion government will pay $260,000. The entire plant will become the property of the province in five years.

Ontario Medical Council Bill.—A bill to provide for the reorganization of the Ontario Medical Council has been introduced into the Ontario legislature. It will provide for an advisory medical committee to deal with all questions affecting the practice of medicine in that province. By this new measure the council will be composed of a member from the University of Toronto, in addition to two named by the senate thereof in lieu of affiliated Trinity and Victoria colleges; one each from Queen's, Ottawa, and Western universities, and every university, college or body in Ontario that may hereafter be authorized to grant degrees in medicine and surgery; two members elected by the licensed practitioners in homeopathy; and eight members elected by registered members of the profession other than those mentioned above. This will provide for eight new electoral districts. All regulations of the council are hereafter to be subject to the approval of the government, and the latter has power to overrule the decisions of the council, which might refuse registration to graduates to any university, college, or other body in Canada having power to grant certificates of qualification for the practice of medicine. The council will have power to suspend a member for any period deemed proper. The Advisory Medical Committee shall consist of three members appointed by the government. This committee will have extensive powers, including the consideration of proposed legislation, regulations, by-laws, relating to medical education, the inquiry into the progress of medical education in Ontario and elsewhere, the recommendation of courses of study, clinical work, scientific research, etc., and also the investigation of new drugs, methods of treatment, etc., and the conducting of experiments and tests thereon. This act is to come into force, July 1, 1919.

LATIN AMERICA

Medical Teaching in Honduras.—During the year 1918, among the students graduated in the Republic of Honduras were six physicians, three druggists and two dentists.

Medical Students in Peru.—According to the report of the rector (president) of the University of Lima for the year 1918, there were in that year 1,471 students at the university, 567 of whom belonged to the school of medicine.

Hospital Physicians Organize in Lima.—There has just been organized at Lima, Peru, an association of hospital physicians, the officers of which are Dr. E. Odriozola, president, and Drs. J. Arce, C. A. Bambarén and C. A. Zevallos.

Mortality in Lima.—For the first time in a number of years, during the year 1918 the deaths exceeded the births in Lima, Peru, the numbers being respectively, 6,575 and 6,271. The disease which caused most deaths was tuberculosis.

Additions to Hospitals in Brazil.—At the Hospital Portugués of Recife, one of the oldest hospitals in Brazil, there are now in process of construction important additions which will provide the institution with new operating rooms, laboratory, etc.

Quarantine Stations in Venezuela.—According to recent presidential decrees in Venezuela, there will soon be begun the construction of an isolation hospital in the vicinity of Caracas and of two quarantine stations at the two ports of La Guayra and Puerto Caballo.——The president has just approved the vaccination regulations adopted by the national bureau of hygiene.

Reorganization of the Board of Health of Ecuador.—By a recent decree issued by the president of Ecuador, the supreme board of health is reorganized into five divisions, namely, (1) bacteriology, vaccination, and inoculation; (2) sanitation of ports and boundaries, epidemics and epizootics; (3) departmental and municipal hygiene; (4) sanitary engineering, statistics and legislation; (5) legal. The board is composed of Dr. Juan C. Segovia, president, and Drs. R. V. Castro, S. Calderón, P. S. Fonseca and L. Montalvo.

Sanitation in Haiti.—According to the report just rendered by the chief of sanitation of Haiti, Dr. M. T. McLean, the reorganization of the sanitary service in Haiti begun in August, 1915, by several physicians of the U. S. Navy, has made satisfactory progress. The sanitary conditions have improved remarkably, especially in the north and south; there are three hospitals doing very good work, a satisfactory garbage system is in operation at the capital, and it is expected that, as soon as the financial situation permits, universal vaccination, and the segregation of lepers may be enforced.

Reorganization of the Health Service in Chile.—On Jan. 1, 1919, a law went into effect in the Republic of Chile providing for the reorganization of the health service which is to be hereafter under a director general of health to be appointed by the president from a list of eligibles presented by the scientific bodies of the republic. There will also be an advisory council of hygiene and an institute of hygiene. There is also to be established a system of regional sanitary service in charge of zone sanitary inspectors, who must be graduates of medicine and must have had at least three years of practice. The first director of public health is Dr. R. Colbarán Melgarejo.

GENERAL

Roentgenologists to Meet.—The twentieth annual meeting of the American Roentgen-Ray Society will be held in Saratoga Springs, N. Y., September 3 to 6, under the presidency of Dr. David R. Bowen, Philadelphia.

Meeting Postponed.—The secretary of the American Public Health Association announces that the annual meeting of this association at New Orleans, which was to have been held October 6 to 9, will be held October 27 to 30.

Health Conference.—A meeting of the health officials of Alabama, Louisiana, and Mississippi was held at New Orleans, April 12, at which the chief topic of discussion was coordination of health activities in the three states.

Flight Surgeons to Meet.—The annual meeting of the National Association of Flight Surgeons, which includes all medical officers in air service of the United States Army, will be held in Atlantic City, N. J., during or immediately preceding the meeting of the American Medical Association.

Sanitarians to Meet.—The seventh annual meeting of the Southeastern Sanitary Association, composed of physicians and sanitarians of the states of Virginia, the Carolinas, Georgia, Tennessee, and Florida, will be held in Rome, Ga., May 13, under the presidency of Dr. Romulus L. Carlton Winston-Salem, N. C.

Luminal Now Available to Physicians.—The Committee on Synthetic Drugs of the National Research Council announces that Luminal is being distributed by authority of Mr. Francis P. Garvan, Custodian of Alien Property and president of the Chemical Foundation by arrangement between Merck & Co. and the owners of the Bayer Co. Physicians interested who cannot secure it from local dealers should communicate with the Bayer Company or with the Chemical Foundation, 110 West Forty-Second Street, New York City.

Society for Epileptics to Meet.—The National Association for the Study of Epilepsy, which is affiliated with the International Liga contra l'Epilepsie, and whose object is to promote the pathologic, therapeutic, social and medicolegal study of the epilepsies, will hold its annual meeting at the Craig Colony for Epileptics, Sonyea, N. Y., June 6 and 7, under the presidency of Dr. William T. Shanahan, Sonyea. The program will be carried out in the three aspects of scientific medical, social and institutional, and interspersed will be clinics and demonstrations of the colony régime by members of its medical staff.

Conference of Social Work.—The forty-sixth annual meeting of the National Conference of Social Work, will be held at Atlantic City, June 1 to 8, under the presidency of Miss Julia C. Lathrop, Washington, D. C.. The chief theme of the conference division on health is to be "Health and Standards of Living," and will be considered under the following topics: housing, family food supply, tuberculosis, medical and nursing care, infant mortality, industrial hazards, and venereal disease. Drs. William H. Welch, Baltimore, and Luther Emmett Holt, New York City, will participate in a discussion of the new health program of children for school aid. Other topics for discussion are: illegitimacy, day nursery, the girl problem, public aid for mothers, handicapped soldiers, state care of mental disease, and health insurance.

Bequests and Donations.—The following bequests and donations have recently been announced:

Rush Hospital for Consumption and Allied Diseases, Philadelphia, $3,000; publication-fund of the College of Physicians and Surgeons, Philadelphia, the Mutual Aid Association of Philadelphia, and County Medical Society each $500, by the will of the late Dr. James Tyson.

Jewish Hospital for the maintenance of a home for aged and infirm, and the University of Pennsylvania the residue, after the payment of bequests, for the establishment, maintenance and equipment of a ward in the hospital as a memorial to her husband, Abraham H. Wolfe, for the benefit of persons supposed to be incurable, by the will of Merriam H. Wolfe. In the event of the failure of the trustees of the University of Pennsylvania to accept this gift within a period of three months, the fund reverts to the Mount Sinai Hospital for the same purpose.

For the erection of a hospital in Baltimore, one third of the estate valued at nearly $5,000,000 of Thomas O'Neill, Baltimore.

Maternity Hospital, to stand as a memorial to the testator's wife, Alice T. Lanning, $40,000, and the Lanning residence to the Mary Lanning Hospital Trust to be used perpetually for the benefit of the Mary Lanning Memorial Hospital as a home for nurses, and $10,000, the interest of which is to be used in keeping in good repair the Lanning residence and lot, by the will of W. H. Lanning.

Agatha Hospital, Clinton, Iowa, $200,000 for the erection of an addition to the hospital in memory of her mother, Mrs. Jane Lamb, a donation from Mrs. Young. The hospital will hereafter be known as the Jane Lamb Memorial Hospital.

Clarence Barker Memorial Hospital, Biltmore, N. C., $50,000 by the will of Mrs. Virginia Purdy Bacon.

Conference on Child Welfare.—The Children's Bureau of the United States Department of Labor has arranged for a series of conferences on child welfare to be held in various sections of the United States during May and June. The conferences will be preceded by a meeting at Washington during the week of May 6 which will be attended by the foreign guests, and a small working committee of American experts and members of the staff of children's bureau. Among the foreign guests expected are Sir Arthur Newsholme, chief medical adviser of the British Local Government Board, who has been largely responsible for the work resulting in lowering of the infant death rate during the war; R. C. Davison of the Juvenile Labor Exchange, London; Mrs. Eleanor Barton of the Woman's Cooperative Guild, an organization of the British workingmen which has helped to secure increased national protection for mothers and babies; Mlle. Valentine Thompson, chief of la vie féminine; Monsieur Pierre Hamp, of the French Ministry of Labor and a well-known authority on education and child labor; Dr. C. Mulon, who was in charge of the crèches maintained by the French government during the war for the children and women employed in the munitions factories, will present the French experiences in child welfare work, and the Belgian representatives will be Dr. René Sand, professor of social and industrial medicine in the University of Brussels, and Mme. Henri Carton de Wiart, who has been much concerned with the care of Belgian refugee children during the war.

FOREIGN

German Deaths from Influenza.—According to estimates made in articles published in German medical journals of recent date, 400,000 deaths have been caused by influenza in Germany during the last eighteen months.

Ducrey Called to Rome.—Prof. A. Ducrey of the chair of skin diseases and syphilis at the University of Genoa has been called to Rome to the similar post left vacant by the death of Professor Campana. Besides the discovery of the streptobacillus of chancroid, Ducrey has published numerous works on various skin diseases.

Urologists Organize in France.—The urologists of Paris and the provinces have recently organized the Société d'Urologie, with Guyon as honorary president; Legueu, president for 1919; Carlier of Lille vice president, and Nogués secretary. Meetings are to be held monthly, except during August, September and October, at the hôpital Necker.

Congress of Medical History.—It is reported that a congress on the history of medicine is to be organized for 1920 at Antwerp. This is to do honor to the fiftieth professional anniversary of Dr. Broecke, the first medical historian of Belgium, and at the same time to celebrate the three hundredth anniversary of the foundation of the "Medical Circle" of Antwerp, which dates from 1620.

Warning Against Medical Career.—The *Nederlandsch Tijdschrift* quotes a Munich exchange to the effect that the Leipziger Verband has issued an appeal to the pupils in the preparatory schools warning them against selecting the medical profession on account of the present outlook for physicians. It advises them to take up some other career, possibly the study of dentistry rather than medicine.

Medical Missionaries in Prison.—Four American medical missionaries in Seoul, Korea, Drs. John Thomas, C. R. Avison, J. I. Ludlow, and J. W. Herst, are reported to have been arrested by Japanese, about April 9, in connection with the Korean revolution early in April. The gendarmes took from the Severence Hospital at Seoul, three Korean patients suffering from gunshot wounds inflicted by the police. The state department is investigating this incident.

Medical Unity for Turkey.—The American Women's Hospital, which is maintaining a hospital at Luzancy, France, a chain of dispensaries in the Soissons and Chateau-Thierry region, and a hospital in Serbia in conjunction with the American Red Cross, has started a campaign to raise $250,000 to be spent in the Near East. A unit of six doctors has been selected who will be stationed in Aleppo. They will be the first women to be put in charge of a hospital in the Turkish domain.

Death of Hallopeau.—One of the masters who have made French dermatology famous, Prof. H. Hallopeau, has just died, aged 77. It was expected that he would be the logical successor of Fournier after the death of the latter, but he missed it by the merest chance, and had the title only of *professeur agrégé* until his retirement. He first described several forms of skin disease, notably dermatitis vegetans, and his research on the abortive treatment of syphilis, his works on leprosy, and his treatises on dermatology and general pathology have carried his name far. Visitors to the hôpital Saint-Louis long remember his kindly and distinguished appearance. Since his retirement on reaching the age limit he has been devoting himself to the care of the paupers in the Maison départementale at Nanterre until his sight gave out.

BUENOS AIRES LETTER

Buenos Aires, March 29, 1919.

Inauguration of the School Years

The courses of the school of medicine began on March 20. The dean, Dr. Julio Méndez, read an address expressing his views in regard to medical teaching. Because of certain criticisms of the behavior of professors he was asked for an explanation, and a motion was presented to the board of directors of the school for an investigation of the matter, but the dean stated that his remarks were of a general character and had no application to the staff of the medical school of Buenos Aires.

Closing of the Port of Bahía Blanca

In the Cámara de Diputados (house of representatives) there was some discussion apropos of the closing of the port of Bahía Blanca, the third in importance in the country, by the national department of hygiene, which does not have at that harbor the necessary materials for the disinfection of ships engaged in foreign commerce. The criticism is based on the fact that it does not seem very good policy to close the harbor for the lack of a few stoves and create serious disturbances to commerce at the very moment when the port of Buenos Aires is closed because of a strike.

Influenza

Some patients with influenza have again arrived on ships from Europe, and there have appeared a few small foci in the city of Buenos Aires, but so far no epidemic has occurred.

The Sociedad Médica Argentina

This organization, which is the most important medical society of the country, has just installed itself in a beautiful building of its own, located at number 1171 Santa Fe Street.

The Asistencia Publica

The Asistencia Pública of Buenos Aires is in charge of the treatment of patients in the capital and also of many patients from other parts of the country. The municipal budget proves therefore occasionally inadequate, especially now when the new budget has not been approved. To obviate this inconvenience and collect funds for the maintenance of the hospitals, there has been formed a commission to obtain voluntary subscriptions and gifts of objects which will be auctioned for the same purpose.

Second Antituberculosis Conference

During the next month of September, there will take place in the city of Rosario the second antituberculosis conference, the organization of which is in charge of a commission presided over by Dr. Clemente Alvarez. The work performed by the commission indicates that the conference will meet with success, and it has already been decided to give popular lectures and to hold an exhibition, which has been offered all possible support by the national and provincial governments, the large municipalities, the national department of hygiene, and the five antituberculous leagues in existence in this country.

Poisonings by Star Anise

During the last four months there have been numerous cases of poisoning in children, due to the use of false star anise from Japan, *Illicium religiosum*. The number of deaths is estimated at thirty. The product was introduced through the custom house and distributed extensively to all drug stores, which made it necessary for the national department of hygiene to confiscate all the anise of both the true and the mock varieties. The most common symptoms have been convulsions and rigidity of the limbs.

Laboratory of the National Department of Hygiene

After being at work for one year, the technical personnel of the Instituto Bacteriologico has been reappointed in a recent decree reorganizing the institution. The sections and the individuals in charge are: hygiene, Dr. Carbonell; plague, Dr. Uriarte; serotherapy, Dr. Sordelli; physics and chemistry, Dr. Wernicke; experimental physiology and pathology, Dr. Houssay; medical zoology, Dr. Bachmann, and parasitology, Dr. Wolffhugel. Dr. Bachmann has been engaged at a salary of $1,500 and an allowance of $100 a month, and has been designated for a mission abroad.

Disease of Horses

During the last few years, there had been observed on different occasions the appearance of epizootics among horses, sometimes localized and sometimes very extended. The last began about a year ago and went through different changes, although finally it extended to practically all the country, causing a large mortality. The technicians of the department of agriculture attributed the outbreak to a food intoxication, although without presenting any data in support of their views. The investigations of Dr. C. Flores (*Semana Méd.*, Feb. 27, 1918) revealed that a brain emulsion injected through the carotid reproduced the disease. Dr. Kraus has demonstrated that the brain of the horses affected, when inoculated into the brain of rabbits, produces a fatal disease, and that from the brain of the latter, there are obtained cultures of a diplococcus, which, when injected cerebrally into horses, produces the symptoms of the disease. The anatomicopathologic lesions correspond to those of Borna's disease.

CUBA LETTER

Havana, April 24, 1919.

Public Health Instruction

The Department of Sanitation is starting a new campaign of public health instruction among the poor classes of Cuba. A number of physicians and hygienists of that department will deliver addresses and give conferences in all the large factories and other places where large bodies of working people gather; the subjects will be hygienic living quarters, proper food and ventilation and prevention of diseases.

The Spanish Edition of the Journal

The physicians of Cuba have welcomed most enthusiastically the Spanish edition of The Journal of the American Medical Association. It will be of great aid to the non-English speaking physicians and will surely bring into closer contact the people of Latin America and North America. It is a queer fact that until 1900 the physicians of Cuba, as well as of the other Latin countries of this continent, turned their eyes to Europe and specially to Paris as the Mecca of medical education, and many French editors published Spanish editions of their journals. Today we know what we can get in the United States and are glad to have so near to us some of the most wonderful institutions in the world. In our judgment, the publication of the Spanish edition of The Journal is one of the greatest steps ever taken by the Americans in their campaign of scientific and commercial propaganda through the Central and South American countries. We congratulate the American Medical Association on their happy idea.

New Building for the Red Cross

The work on the new building of the Cuban Red Cross has already begun; it will be located in the central avenue of Havana, the old Prado or Paseo de Marti, and the total cost of the building is estimated at $1,000,000.

Epidemic Lethargic Encephalitis

No cases of this disease have been officially reported yet, although some have been given as suspicious. The board of health has sent a circular to all physicians urging them to report at once any case showing symptoms of paralysis and coma. The article on "Epidemic Encephalitis" by Peter Bassoe, M.D., which appeared in the last Spanish edition of The Journal, has had a wide circulation.

Personal

Dr. Max Einhorn of New York visited Havana last month, giving a lecture in the Academia de Ciencias Medicas on a new method of investigating the motility of the intestine.

Drs. A. Inclan and F. Leza have been appointed assistants in orthopedics and laboratory diagnosis, respectively.

Drs. J. Ramirez Olivella and E. de Aragon are the editors of the new *Revista de Obstetricia y Ginecologia.*

PARIS LETTER

Paris, April 3, 1919.

International Red Cross Conference

In order to determine on a definite line of action, the Comité des Sociétés de la Croix Rouge extended invitations to the most renowned specialists of the world to take part in this conference which convened at Cannes, April 1. Dr. Roux, director of the Pasteur Institute of Paris, was unanimously elected president. At the first session, Dr. Henry P. Davidson, president of the war committee of the American Red Cross, stated that the object of the conference was to organize a central committee for all the national Red Cross societies, this central board to sustain and direct the efforts of the various national societies so as to keep before the world the importance of hygiene, good health and measures for public safety. Each society is to maintain its independence, the central committee merely coordinating their efforts. At the second session, Colonel Strong of the American Army, and Dr. Biggs of New York, outlined the plans for the creation of the permanent international bureau. The work of this conference will be reported to a congress of all the Red Cross societies to be held in Geneva thirty days after the declaration of peace.

An American Hospital at Reims

The national American executive council for French wounded has decided to erect a hospital at Reims, for which purpose $100,000 have already been collected. The families of American soldiers who died in France will be asked to contribute to and take an interest in this hospital in memory of their sons who fought by the side of the French soldiers. This hospital will be turned over to the city of Reims on its completion.

Replacing the Physicians in the War Devastated Regions

The ministre des régions libérées has informed the physicians who formerly were resident in the war devastated zones that to enable them to return to their former place of residence as quickly as possible, they will be awarded a monthly indemnity of 500 francs for a period of two years, irrespective of any other allowance which they may receive for participating in the Services publics d'assistance et d'hygiène, especially in the Assistance médicale gratuite. Furthermore, these doctors will each receive a maximum advance of 10,000 francs, to be charged to their indemnity for damages sustained through the war, so that they can rehabilitate themselves and provide necessary equipment for professional work.

Franco-American Friendship

For the purpose of celebrating the second anniversary of the entrance of the United States into the war, the University of Lyons recently entertained, in the large amphitheater of the faculty of law and of arts, the 400 American students who are attending the various faculties of the city. All of the professors of the Lyons university assisted at this function.

Swiss Physician Decorated

Dr. Baup of Switzerland, medical director of Evian-les-Bains, has been made chevalier in the Legion of Honor for services rendered during the war to the repatriates.

Personal

At the meeting held April 1, the Académie de médecine elected M. Forneau, chef du service de chimie at the Institut Pasteur, a member of the section on pharmacy. At the meeting of April 8, Dr. Sergent, physician to Paris hospitals, was elected a member of the section of medical pathology. Dr. Yersin, director of the Pasteur Institute of Nha-Trang (Indochina), and Dr. Delagenière of Mans were elected national associates.

MADRID LETTER

Madrid, March 8, 1919.

The Social Movement Among Spanish Physicians

During the whole month of February and the few days that have elapsed of the present month, the medical event of the day has been the movement which has received its chief impulse from the assembly of the boards of directors of the *Colegios Médicos* (medical guilds) of Spain.

The *Colegios Médicas* are guilds which have had their ups and downs until recently when the government ordered the so-called *Colegiacion Obligatoria,* which means that it is obligatory for every physician in exercising his profession to belong to a *Colegio* (guild) which apportions the taxes among all its members, and must attend to all professional activities, as bill collecting, cases of illegal practice and quackery, interpretation and violation of sanitary laws, etc. The Boards of Directors of the *Colegios Médicos* (medical guilds) are elected by the physicians themselves, and are supposed to represent the social and professional aspirations of their profession. There is a *Colegio* in each of the forty-nine provinces of Spain.

In response to a call issued by the boards of directors of the *Colegio de Médicos* of Madrid, a meeting was held in the capital from the 27th to the 29th of January by the representatives of the boards of directors of thirty-three provinces and in addition ten others sent in their adhesion to the movement, thus forming a total of forty-three out of the forty-nine provinces in Spain.

In order to avoid all that might give any *Colegio* too much importance over the others, there was chosen for president of the assembly the president having the longest service among those present, Dr. Martín Istúriz of Palencia. The sessions were devoted almost entirely to comment on the motion presented by the accounting officer of the *Colegio de Médicos* of Madrid, Dr. Velasco Pajares. On the 29th the closing session was held, when the proceedings were approved, and there were adopted the following conclusions that summarize the so-called minimum program of the medical profession:

RESOLUTIONS OF THE ASSEMBLY OF MEDICAL GUILDS OF SPAIN

The Assembly of the *Colegios Médicos* of Spain has voted the following conclusions:

First: The medical profession considers as the *minimum program* of its aspiration for immediate realization:

1. Payment by the national government of the city and court physicians (coroners), and health officers.
2. That city physicians be made also health officers.
3. That the question of the pensions to widows and orphans of physicians who were victims of the influenza epidemic be decided immediately without red tape delays.
4. That the national government shall guarantee the salaries of physicians employed in medical relief by the provincial governments.

Second: In order to bring about ends which are considered a matter of mere justice, all necessary means will be employed; and for this purpose, there is appointed an executive committee with offices in Madrid, consisting of Drs. Almarza, Piga, Velasco Pajares, Coca, Albiñana, Criado y Carro to act in agreement with the chairmen of all the provincial *Colegios Médicos,* so that a common action will be exercised in so far as the authorities are concerned, in order to obtain the granting of the just claims of Spanish physicians.

The *Colegios Médicos,* which constitute the legitimate representation of the profession, wish to obtain wider powers which will primarily be of benefit to the public health of Spain. It will be of their incumbency to submit lists of eligibles to fill vacancies for city physicians and health officers, from which lists the city councils shall appoint their physicians. They will have charge of the administration of the funds for the asylum for physicians' orphans, and of filling vacancies in the institution; they will have free mailing privileges, which will facilitate the relations of the *Colegios* with official organizations and with their members; they will prepare lists of the physicians who have to form part of the draft boards and of all those forming part of official organizations who are now appointed on political grounds; and they will also have a direct representation in the organization of the sanitary services of their respective provinces to avoid the interference of politics in sanitary work.

The Assembly of the *Colegios Médicos* depends, for carrying out this minimum program, on the cooperation of all medical organizations which are ready to carry out the measures now in preparation by the executive committee, that will assume a radical form in case no assurances are received before March 15 that the government is in sympathy with the purposes of the medical profession of Spain.

THE EXECUTIVE CENTRAL COMMITTEE

The Executive Central Committee is composed of physicians belonging to the board of directors of the *Colegios Médicos* of Madrid and of editors of medical journals, the subscribers of which are chiefly rural physicians or city physicians in small communities. Thus we find the name of Dr. Albiñana, editor of the journal, *La Sanidad Civil*, who, a few days before, had organized a conference with 300 physicians present and more than 7,000 adherents, and that of Dr. Almarza, director of the *Boletin de la Asociacion de Médicos Titulares*, the meeting of which society followed immediately that of the boards of directors of the *Colegios*. At these two meetings, the same memorials and recommendations were approved. In order to secure joint action, editors of these two journals were incorporated in the central committee.

THE MEMORIAL TO THE KING

On the invitation of the president of the *Colegios de Médicos* of Madrid, Dr. Ortega Morejón, there was a meeting, February 30, of the representatives of the *Colegio Médicos* with the sole exception of those of the four provinces of Catalonia. At this meeting, those attending decided to insist on their program, exhausting every possible argument with the government before adopting a rebellious attitude, although if no attention is paid to their demands, they will, as a last resource, decide on a strike.

Those attending the three assemblies enumerated before, addressed a message to the king, in which special stress is laid on the fact that municipalities owe physicians at the present time more than twelve million pesetas (about $2,400,000), and that twelve city physicians, 1,500 health officers and 500 court physicians cannot get justice done to their claims. The memorial ended appealing to the king to intervene in the matter in accordance with the constitution.

THE MEDICAL STRIKE IN SPAIN

All Spanish physicians have received a circular accompanied by a pledge to be signed by them, and a copy of the instructions which should govern the conduct of every physician in the collective action contemplated. The instructions are tantamount to ordering a strike, prescribing what court physicians should do to avoid performing their duties, and even going if necessary, to the extreme of resigning their positions, and requiring others to render medical assistance to the poor, only of their own free will and not as official duty, and making the patients acquainted with this fact.

This propaganda has yielded the logical results, and the physicians of Cartagena and of Jerez de la Frontera, as a protest against the nonpayment of their salaries, have decided not to take part in the medical work connected with the draft in their respective localities.

LONDON LETTER

London, April 7, 1919.

Legislation to Forbid Vivisection of Dogs

A bill to prohibit any experiment of a nature to cause pain or disease to dogs, either with or without anesthetics, has been introduced into Parliament and is being considered by a standing committee. In opposing it, Sir Watson Cheyne asked the committee to realize the responsibility they were taking. He sympathized with the objects of the bill because he was a dog lover himself. Speaking as a surgeon who, for the last forty years, had almost every day had the life and health of patients in his hands, he said that he could not afford, with that responsibility constantly before him, to lose any possible source of information which might help him to carry out his work better. If the clause were passed, very great sources of information of the greatest value to the life and health of humanity would be denied to them. He could state definitely that every care was taken to see that no unnecessary suffering, and, indeed, he might say that no suffering, was caused to dogs by the experiments. Referring to the vivisection experiments conducted in connection with cancer investigation, he said: "If you pass this clause as it stands you may be the cause of the death of many people who would otherwise have lived. I implore you not to take that responsibility." Nevertheless the bill was passed through the committee stage by a majority of 17 to 13 votes.

In a letter to the *Times*, Sir Edward Schäfer describes the result as disastrous and as revealing an appalling depth of ignorance among our legislators. He points out that "the only sure basis of medicine is physiology, and physiology is absolutely dependent on the dog for knowledge which is to be directly applied to man. In this respect, no other animal can replace it; indeed, it is not too much to assert that almost all human physiology is based on information originally acquired from experiments on dogs. The immortal discovery of Harvey, from which physiology and with it medicine, as a science, date their real origin, was founded on experiments and observations on this animal. All modern knowledge of the action of the heart and circulation, of the functions of the brain and nervous system, of digestion, of external and internal secretions, of nutrition and metabolism, originated in and is based on experiments on dogs. The passage of such an act would completely arrest the progress of physiology in this country, which, since the time of Harvey, has always been in the forefront in regard to that science, more, perhaps, than any other. Dogs are already absolutely protected from suffering in any experiments which require to be made on them. No operation whatever can be performed on a dog without the express sanction of the home secretary; all operations must be conducted under complete anesthesia, and any dog suffering pain as the result of an operation must immediately be killed."

A State Medical Service: Sweeping Suggestions by the Labor Party

The Advisory Committee on Public Health, appointed by the labor party to consider the organization of preventive and curative medical services and hospitals and laboratory systems under a ministry of health, has reported in favor of the institution of a state medical service. The report stated that one of the most important duties to be undertaken by the ministry of health will be the reorganization of the whole mechanism of medical service, so that the greatest possible utilization is made of medical science, not merely for the treatment and prevention of disease, but for the inauguration of those systems of living, working, and enjoying leisure which experience and scientific research show to be capable of producing the greatest happiness for all. It is pointed out that while infant mortality has been greatly lowered by educational means in the last decade, nothing comparable has been done to extend the average expectation of life of adults.

The conditions of industrial life shorten life very markedly. The Registrar-General's decennial supplement shows that of those who survive over 15, the average period of life of purely industrial workers is 49.50 years; of purely agricultural workers, 67 years. The national service cards show that in certain occupations from 30 to 40 per cent. of the workers over 40 years of age are graded as unfit for military service. Insurance statistics show that in certain occupations from 30 to 40 per cent. may be unable to work for some period in each year owing to illness. The number of deaths from consumption is 700,000 a year, a destruction of life emulating that of the war. In large cities, such as Glasgow, 48 to 50 per cent. of the population live in one or two rooms tenements, and 50 per cent. of the children of the poor are found to be suffering from rickets. In Finsbury (a London district) the death rate per thousand of infants has been found to vary from forty-one in well-to-do parts to 375 in the slums. Venereal disease is widely prevalent, and fills hospitals and asylums with cases of disease which might be almost wholly prevented. The physician, having little opportunity to study or uphold the principles of preventive medicine, has failed to protest against industrial and housing conditions which have led to a most serious deterioration of national health and happiness.

So much of the physician's time is spent on the art of medicine, in visiting, humoring, and encouraging his patients, that too little remains for acquiring and practicing the science of medicine. Devoted attendance and kindly endeavor cannot make up for ignorance of the advancement of medical science, but they often cloak a failure to prevent illness and loss of working capacity, or to save life.

The report lays it down that a state service should be under democratic control, both at headquarters and at every local center. There must be nothing in the scheme to take away the choice of physician from the patient, but rather to widen and amplify the very restricted choice he now possesses. It must be the aim of the service to put every discovery of modern medical science, every class of specialist, every comfort of the best type of nursing home, sanatorium, and hospital within the reach of all, rich and poor. It must not prevent private practice, and no physician or patient must be forced to take any part or share in it against their desire. The present hospital and panel services must be radically reformed, and the coming service must not be bureaucratic, but one more resembling the chapters or lodge of a skilled craft. Each medical group, and not the single physician, would form the unit and would have the scientific laboratory for diagnosis and research, and the hospital and consultative center as its headquarters. Each unit would have control over its own local professional affairs, and be linked up to all other units. Along with the local lay health committee it would be responsible for the health of the area it served. It would try to ensure that supplies of food were wholesome and adequate, and that adulteration and sophistication were prevented, that weakly individuals were not overworked when ill or requiring relaxation, that infected individuals were not infecting others, and that infants and young children were being reared in a sensible way and on suitable food.

THE CLINICAL AND SCIENTIFIC MEETING OF THE BRITISH MEDICAL ASSOCIATION

Special Correspondence

The special clinical meeting of the British Medical Association, which replaced the usual annual meeting, differed considerably from that function. It might be described as a war meeting, for the subjects discussed were all connected with the war, and among both audiences and speakers khaki predominated over civilian dress. It was an excellent idea to hold the meeting early in the year so as to allow the large number of medical officers from the dominions and the United States now in Europe to attend. Many of them are here for the special graduate courses which have been organized for their benefit. At every meeting and casual gathering the uniforms of these officers were in evidence among those of the predominant British. Though no new discovery of any importance was announced, the meeting was a great success from every point of view. It was well attended, the discussions were animated, and the large number of speakers from the dominions and the United States who took part in the discussions rendered it more representative of the medical knowledge of the English-speaking world than usual. The American officers expressed great approbation of the arrangements, and indeed surprise that so soon after the war the proceedings ran so smoothly. They were loud in praise of the hospitality and help they everywhere received. The large lecture rooms of the Imperial College of Science were well suited for the discussions and demonstrations, but they were often overcrowded, many of the audience having to stand, and at one of the surgical meetings the room was packed, so that late comers could not even enter. This was no doubt largely due to the reduction of the number of sections to three, as stated previously (The Journal, March 22, p. 880). The main object was to garner and compare the experiences of the war, but as these had been published during that long struggle there was no opportunity for novelty. However, the discussions and demonstrations were most instructive.

The Presidential Address

Instead of being delivered as usual, the address of the president, Sir Clifford Allbutt, was printed and distributed to members. He took for his subject "The New Birth of Medicine," which he discussed in his well-known philosophic vein and elegant diction, which place him alone among contemporary English writers. Age has not impaired that subtle intellect. He claimed that we met at the greatest moment in the history of medicine; not merely because this was a gathering of the physicians of commonwealths, dominions, colonies, and friendly nations, to consider the lessons of a great war; not only because the medicine of modern peoples and empires had vindicated its ascendancy in the greatest war of all time, but chiefly because at this moment it was revealed to us that medicine had come to a new birth, and in this regeneration had fought on no unequal terms with other arms in a glorious campaign. This new birth was nothing less than the enlargement of medicine from an art of observation and empiricism to an applied science founded on research; from a craft of tradition and sagacity to an applied science of analysis and law; from a descriptive code of surface phenomena to the discovery of deeper affinities; from a set of rules and axioms of quality to measurements of quantity.

War Neuroses

The discussion on this subject was introduced by Lieutenant-Colonel Mott. He said that in no previous war had such a vast number of men been disabled by functional nervous disease; but in no previous war had such conditions existed. They were the unprecedented exposure to the continuous physical effects of high explosives and poison gas and to all the developments of scientific barbarism. Moreover, the periods in which men had been exposed to the terrifying effects of modern trench warfare had exceeded all previous records. The conscripted army had included all sorts and conditions of men, and we had now found out what a large proportion of the male population of a highly civilized country possesses a neurotic or neuropathic predisposition. In 1917 it was calculated that one third of the unwounded and one seventh of the total discharges, including the wounded, were permanently unfit on account of functional nervous or mental diseases.

The war office authorities recognized three forms of war psychoneurosis—shell shock, hysteria and neurasthenia. The term shell shock led to much misconception. It was a natural conclusion, at first, that men who had been exposed to the unprecedented stress of bombardment should suffer from commotio cerebri. But a great many returned as suffering from shell shock would have been more appropriately designated "shell shy." It was extremely difficult to differentiate commotional shock from emotional shock, for both may be attended by unconsciousness and followed by hysterical or neurasthenic symptoms. Still there was no doubt that men suffered from commotional disturbance of the brain without any signs of injury on the body and were the subjects of organic changes, due to the forces generated by the detonation of high explosives. This was proved by the fact that the cerebrospinal fluid, withdrawn by lumbar puncture, contained blood and came out under pressure. Moreover, the frequency with which rupture of the drum of the ear, deafness, labyrinthine changes, and voltaic vertigo occurred showed that the explosion was sufficient to cause a commotion of the brain as severe as might be caused by a blow on the head. Further proof was the fact that microscopic hemorrhages had been found throughout the brain in cases with no visible sign of injury on the body. These cases were commotional shock, as against emotional shock. On the other hand, a soldier born with or having acquired emotivity tended sooner or later to develop one or other form of nervous complaint. A shell burst near him and he saw the flash and was blinded by it, and remained functionally blind; he heard an explosion and was temporarily deafened by it and remained deaf, this being in a sense a method of defending himself against unbearable sights and sounds. These and other conditions of the same sort were curable by suggestion given in opposition to the emotional trend producing the phenomena.

Cases might, of course, occur in which both commotional and emotional shock were present. Though a neuropathic tendency greatly assisted the onset of shock, this might occur in sound individuals. The instincts connected with the emotions of fear and anger were all-important, but equally so was the herd instinct, and morale, good or bad, in a regiment was largely dependent on the instinctive suggestibility of man. A British general was reported to have said: "Ten per cent. of a regiment will follow you to the gates of hell; 10 per cent. will fall down or run away; and the remaining 80 per cent. will follow either." It might therefore be supposed that in the 10 per cent. who followed anywhere the primitive emotion of anger, with its instinctive reactions, was inborn and dominant in the personality, and that to fight was the instinctive reaction of self-preservation in these men. But, in modern trench warfare anger was impotent. The soldier could neither fight nor run away. He could only crouch and hide himself, the instinctive attitude of the timid animal when threatened with danger. In treating the functional neuroses, Dr. Mott did not regard psychotherapy as important, but it was valuable in hysteria.

Prognosis with Special Reference to the Assessment for Pension Purposes and to the Capacity of the Worker

Dr. Thomas Lewis read a paper on this subject. He said that the great defect in the system of examining recruits had been reliance on methods suitable enough in forming or completing the diagnosis of grave cardiac disease, but unsuited in detecting the earliest manifestations of ill health. In sorting men who are the subjects of serious cardiac affections, a small number are at once and easily placed in a group as totally unfit for service. They showed manifest and obvious signs of disease. The chief work came in assessing fitness or unfitness in the far larger group of those who bordered on disease. In these, the great majority, the physical examination, the special examination by means of mechanical or electrical instruments failed to achieve our purpose. The secret of successful prognosis lay in actual tests of efficiency. In the great majority of recruits, whether suspects of cardiovascular defects or not, actual tests of endurance are the only tests on which reliance can be placed.

These tests are equally applicable in sorting convalescent soldiers and in assessing pensions. Because they were not used, a large proportion of present assessments were grossly at fault.

Whenever a soldier failed to show such unmistakable signs of ill health as to leave no doubt as to his condition, his reaction to work must be observed in assessing his disability. In many cases the act of undressing might be a sufficient test to elicit breathlessness. In some a short hopping test sufficed; in others more strenuous and prolonged effort was required to produce signs of breathlessness and fatigue. The measure of efficiency was the amount of work undertaken to provoke objective symptoms. But such tests should not replace the physical examination; they should supplement, or be supplemented by, the latter. Many men performed long and strenuous work in the front line and on the forced march, yet were the subjects of serious structural heart disease. Many men presenting clear signs of developed mitral stenosis or aortic disease showed, when deliberately tested, an almost or quite perfect tolerance of hard physical work. Exercise tests would not eliminate such recruits, neither would they form a sufficient basis of prognosis in men returned to civil work. Nevertheless, in structural disease of the heart exercise tests were of considerable consequence. Up to the end of January, 1919, over 50,000 men had been discharged from the army and navy for affections attributable to the heart. Many more remained in the army. He calculated that of the number one third to one half were suffering before they joined the service. Of the 50,000 cases of so-called heart disease, only 5,000 were suffering from heart disease in the structural sense.

Sir James Mackenzie (who presided) said that the patient wanted to know what bearing his symptoms had on his future and the physician must be prepared to answer him. This meant not only a wide knowledge but a discriminating judgment. It meant a clear idea of the value of symptoms, their meaning and their bearing on the evolution of disease. Let no man think that this could be achieved by the aid of elaborate instruments, by modern magic, so to speak. It could only be achieved by close and careful observation of many patients over a long period of time and by diligent thought. But the progress of medicine depended on this observation and this thought, for after all the only indication that a man was unwell was his symptoms. The field of medicine had been long too much neglected in favor of so-called new methods, which at best were but a means to an end.

Gunshot Wounds of the Chest

Col. T. R. Elliott, F.R.S., opened the discussion. He said that after a wound of the chest the respiration was shallow and quickened. On the injured side the intercostal muscles were said to show an increased tone, "guarding the wound within," and the diaphragm was relaxed in the complete expiratory phase. There was reason to suppose that also the bronchiolar musculature was reflexly contracted, which damped down the current of air. The lung tended to be small on the wounded side and to collapse everywhere. In cases of hemothorax the coagulation was interfered with by the respiratory movements, so that fibrin was to a certain extent whipped out of the blood. The pleura reacted by a mild inflammation (effusion) to some constituent of the hemothorax, even when sterile. The fluid mixture of whipped blood and pleural effusion could be withdrawn by aspiration; the clot could not. The clot developed in time into a tough jacket, which restricted the lung to the size it was at the moment confined and hindered subsequent expansion when the fluid was removed. Therefore, a large hemothorax should be removed as completely as possible at the earliest date. If the hemothorax was chiefly fluid, early aspiration would suffice. Even on the second or third day *this might be done.* With a large hemothorax it was difficult to be certain that clot was present. More than one failure in attempted aspiration was necessary before it could be concluded that the failure was due to excess of clot. When this was proved, thoracotomy, evacuation, and closing completely without attempting drainage was the treatment. But if delayed so long that the clot had time to organize this was unsatisfactory. The urgent problem of chest wounds in this war, however, was checking the spread of infection. Half of the deaths from chest wounds at clearing stations and all the deaths on the lines of communication were due to sepsis. Of septic hemothorax cases, 50 per cent. were fatal under the average skill available in hospitals. Those who survived, thanks to early detection and adequate drainage, were in hospital twice as long as sterile hemothorax cases. One third of them were invalided out of the service, whereas practically every case of sterile hemothorax got back to duty.

Malaria

Lieut.-Col. S. P. James discussed the risk of the spread of malaria in England, which was free from indigenous disease until August, 1917, when cases were discovered among soldiers and civilians who had never been out of the country. The total number of such cases was now 326. Demobilization would result in malaria carriers being scattered all over the country. In a town in which indigenous malaria occurred it was not scattered at random but occurred in particular houses where there was a carrier and did not spread to neighboring houses. Hence such houses were called "malarious houses." This could be explained only on the hypothesis that the particular mosquito which bit the carrier remained in that house or if it fled outside returned to it. These houses were very favorable for mosquitoes. They were old fashioned, containing many dark corners where the mosquitoes settled. Such dangerous dwellings could be detected by ascertaining whether mosquitoes could be caught in them day after day for a week or more during summer. The factor which determined the occurrence of indigenous cases of malaria was not the abundance of carriers or of anophelines but the degree in which there was close and continuous association between the malaria carrier, the anopheline and the susceptible person. This was likely to occur only in the particular type of dwelling which the anopheline selected as its resting and feeding place. It would be difficult if not impossible to find a locality in England in which antilarval measures would be "worth the candle," but anophelines could be kept out of houses by whitewashing and other cleaning up.

Sir Ronald Ross (who presided) said that he was not entirely sure that quinin acted as a direct poison to the malarial parasites. He suggested that it stimulated the production of some antibody which destroyed them.

The Projected Antivivisection Legislation

In connection with this matter (mentioned in the last letter to The Journal) Sir William Osler moved the following resolution: "This meeting of the combined sections of pathology and preventive medicine of the British Medical Association learns with dismay of the possibility of the passage through the House of Commons of a bill to prohibit experiments on dogs. The anatomic and omnivorous habit of the dog, together with the fact that it can be kept in health and comfort under the conditions imposed by laboratory work, render the larger sort the only available subject for experiment in important fields of physiologic and pathologic investigation. The prohibition would have the deplorable effect of hampering the progress of medicine and of rendering Britain alone among the civilized nations unable to contribute to progress in a department of research in which it has played a distinguished part." Sir William Osler said that from Galen to Victor Horsley progress was based on experiment.

Col. Haven Emerson, U. S. Army (who presided), said that it was impossible for physiologists and laboratory workers to bear the entire burden of conducting the conflict against the legislative attacks on the freedom of science. The resolution was not enough; it must be followed up, and the lives of parliamentary representatives made miserable until they adopted the proper point of view.

Venereal Diseases

Sir William Osler presided over the discussion on venereal diseases. He said that the four pressing questions were notification, prevalence, prevention and treatment. We could never go far with prevention and cure until the cases were *notified and under full control.* Laws enforcing this were now effective in parts of Australia and of the United States. Naturally there were objections just as there were to the notification of tuberculosis, but notification could be carried out with secrecy, and it was the only measure which would enable the profession to keep control of the cases. Syphilis was as prevalent as ever, though possibly less virulent. Previous measures had failed. The educational and moral campaigns had helped but had not succeeded. To put venereal diseases in line with other acute infections would be to ensure thorough treatment of each case, the control of harlotage and of infected harlots, the prevention of marriage of infected persons, and the provision of methods and measures of disinfection for persons who had been exposed, especially arrangements for early disinfection at the venereal centers.

Col. L. W. Harrison, who is in charge of the well-known military hospital for venereal disease at Rochester Row, London, opened the discussion. He said that in 1916 ablution chambers were set up in barracks, where men could disinfect by irrigating with potassium permanganate and inunction with calomel ointment. Generally they were not a success because medical officers did not take a great interest in them. In 1918 a new system was adopted. A man could have on application a small bottle of potassium permanganate solution with which to swab the parts and a tube of 30 per cent. calomel ointment, some to be squeezed into the urethra and some to anoint the parts after exposure. The results so far had not been particularly striking for the whole country, though there was no doubt as to the efficacy of these methods when properly applied. In the London district the admission rate per thousand troops per annum had been reduced by these measures from 95.6 to 32. Coming to the second line of defense, most of the abortive methods of treating gonorrhea had been tried in the British army, but only on a small scale, as the men reported too late. The results confirmed those obtained on a much larger scale in the Australian army. Success depended on the man's reporting within twenty-four hours of the onset. The best results were obtained by the following method: 1. After urinating disinfect the glans and meatus with 1:2,000 mercuric chlorid or with spirit. 2. Irrigate the whole urethra with 1:4,000 potassium permanganate. 3. Inject 10 per cent. argyrol or similar silver salt and make the patient retain it for twenty minutes. Repeat this twice daily for three or four days. 4. Irrigate once daily with potassium permanganate for from four to six more days. In the later stages intermuscular injections of succinimid and other compounds of mercury were tried. They frequently brought about a rapid diminution or disappearance of discharge, but in the long run they failed to curtail the disease. Vaccines had been tried, but the only one which seemed to hold out hopes of success was that prepared by Capt. D. Thomson in the Rochester Row Laboratory. In gonorrheal arthritis excellent results had been attained from the intravenous injection of antityphoid vaccine, suggested on the principle of "pyrogenic" therapy.

In the treatment of syphilis eight injections of 0.3 gm. of arsphenamin and six of 0.75 grain of calomel were given in twenty-eight days. Up to November, 1915, there was no trouble of any moment, but then a series of severe cases of dermatitis began and seven proved fatal, chiefly from pneumonia or toxemia complicating the dermatitis. In March, 1916, an interval was introduced into the course so that those susceptible to arsphenamin could display the effects and a careful watch was kept for the first sign of erythema. Later a second interval was introduced. These precautions bore fruit, for among 16,000 patients subsequently treated only five deaths were traced, some of which appeared to be due to other causes. The number of clinical relapses amounted to 1.1 per cent. for those patients who had taken 2.4 gm. of arsphenamin.

Colonel Ashbourne, U. S. Army, stated that in the American Army the venereal rate in France was below half of the best rate they had ever obtained before this war. The campaign against venereal disease had been very successful. In the American Expeditionary Forces moral, mental, educational, recreative and religious influence had borne good results, as well as threats of punishment, especially the threat of retention in France, which had been very effective.

Marriages

Stanton Harold Barrett, Lieut., M. C., U. S. Army, Chattanooga, Tenn., formerly on duty with Base Hospital No. 80, American E. F., now instructor in bacteriology American E. F. University, Beaune, France, to Miss Catherine Clarke of Owensboro, Ky., Aug. 24, 1918.

Johannes Benedict David de Beer to Miss Mabel Adelia Jarvis, both of Brooklyn, April 12.

Charles William Larrabee to Miss Dovie Mae Collins, both of Gainesville, Ga., April 14.

Lyle Millan Mason to Evlyne Wailes Brewer, both of Washington, D. C., March 19.

Abraham Lear Morris to Miss Fanny Reeves Ellison, both of Chicago, April 9.

Herbert A. Adler to Miss Emily Frisch, both of Brooklyn, April 7.

Deaths

Lewis Theophilus Griffith ⊕ **Lieut.-Col., M. C., U. S. Army,** New York City; Albany N. Y., Medical College, 1897; aged 45; a member of the Association of Military Surgeons of the United States; who entered the military service as lieutenant and assistant surgeon, First New York Volunteer Infantry, in 1898, serving through the war with Spain, then was made acting assistant surgeon, U. S. Army, until March, 1901, when he was promoted to captain and assistant surgeon, U. S. Volunteers, and ten months later to major and surgeon, U. S. Volunteers; who served as assistant in the military hospital at Honolulu, from August, 1898, to December of the same year; and in September, 1900, was sent to the Philippine Islands, and at the outbreak of the World War reentered the service as major, M. C., and was sent to France in September, 1918, in command of Base Hospital No. 76, Vichy; died from disease, at Vichy, April 8.

H. Augustus Wilson ⊕ Philadelphia; Jefferson Medical College, 1879; aged 65; one of the most eminent orthopedic surgeons of the United States; for thirty-nine years a member of the faculty of his alma mater as clinical lecturer, clinical professor and professor of orthopedic surgery; from 1879 to 1892 a lecturer in the Philadelphia School of Anatomy; professor of mechanical surgery in the Philadelphia Polyclinic from 1885 to 1897 and thereafter emeritus professor; clinical professor of orthopedic surgery in the Women's Medical College of Pennsylvania, Philadelphia, in 1889; orthopedic surgeon to the Jefferson Medical College, St. Agnes' and Philadelphia General hospitals; died at his home, April 16, from uremia.

George W. Wagoner ⊕ Johnstown, Pa.; Western Reserve University, Cleveland, 1878; aged 63; treasurer of the Medical Society of the State of Pennsylvania, and president in 1909; secretary, member of the board of managers and of the surgical staff of the Conemaugh Valley Memorial Hospital; mayor of Johnstown from 1896 to 1899, and president of the board of fire commissioners in 1906; one of the sufferers in the Johnstown flood, but who nevertheless worked heroically throughout that period; died at his home, April 26, from pulmonary embolism.

Robert Henry Gilliford ⊕ Pittsburgh; Medical College of the State of South Carolina, Charleston, 1874; aged 69; president of the Bank of Secured Savings, Safety Real Estate Company, and Security Improvement Company, Pittsburgh; for many years a member of the staff of the Allegheny General Hospital, and poor physician of Allegheny City; for two years a member of the common council and for nine years a member of the select council; president of the Allegheny Fire Insurance Company, died at his home, March 28.

Nomus Paige, Taunton, Mass.; Dartmouth Medical School, Hanover, N. H., 1861; aged 79; a member of the Massachusetts Medical Society for fifty-five years; a member of the staff of the Morton Hospital, Taunton; physician to the Taunton jail for twenty-five years; a trustee of the Taunton Savings Bank; one of the founders and directors of the Taunton River Mills; organizer of the Taunton Electric Light Company, and manager from 1882 to 1901; died at his home, April 16.

Reuel Baker Kimball, New York City, and Sea Bright, N. J.; College of Physicians and Surgeons in the City of New York, 1880; aged 64; a fellow of the New York Academy of Medicine; attending physician to the Babies' Hospital, and consultant to the Monmouth Memorial Hospital, Long Branch, N. J.; died in the Stern Hospital, New York City, April 18, from bronchial pneumonia.

Jefferson Scales, New Brighton, Staten Island, N. Y.; Jefferson Medical College, 1867; aged 73; a member of the Medical Society of the State of New York; and once president of the Richmond County Medical Society; a Confederate veteran; consulting physician to the S. R. Smith Infirmary, and St. Vincent's and Sea View hospitals; died at his home, April 14.

Henry A. Page, Newport News, Va.; Yale University, New Haven, Conn., 1865; aged 79; surgeon of Massachusetts Volunteers during the Civil War, and a practitioner of Boston; an inmate for many years of the National Soldiers Home, Newport News, Va.; died in the veteran's ward of that institution, March 20.

⊕ Indicates "Fellow" of the American Medical Association.

Amanda Lockman Shelton, Bloomfield, Iowa; College of Physicians and Surgeons, Keokuk, Iowa, 1892; aged 68; for many years a member of the staff of the Bloomfield Hospital; while suffering from despondency and mental derangement, hung herself in the Bloomfield Hospital; April 9.

Robert Campbell MacGregor, Duncan's Station, B. C.; Manitoba Medical College, Winnipeg, 1896; aged 50; formerly of Saginaw, Mich., and professor of physiology in the Saginaw Valley Medical College; died at his home, April 2, from cerebral hemorrhage.

George Rice Adkin, Grand Rapids, Mich.; Grand Rapids, Mich., Medical College, 1899; aged 42; formerly lieutenant, M. R. C., U. S. Army, was found dead in his room, in Detroit, April 14, from the effects of an overdose of chloroform.

John Devoe Martinez Cardeza, Brooklyn, N. Y.; University of Pennsylvania, Philadelphia, 1877; aged 78; for many years a practitioner of Philadelphia; died at the home of his son in Brooklyn, April 15, from pneumonia following influenza.

Frank Howard Ransom, Buffalo, N. Y.; University of Buffalo, N. Y., 1900; aged 47; a member of the Buffalo Academy of Medicine, and consulting obstetrician to the Buffalo General Hospital; died at his home, April 2.

Bryan O'Brien, Philadelphia; University of Pennsylvania, Philadelphia, 1881; aged 78; also a pharmacist; a petty officer in the Navy during the Civil War; died at the home of his daughter in Philadelphia, April 11.

Carl W. Lindner, Martin, Fla.; Miami Medical College, Cincinnati, 1875; aged 74; for many years a practitioner of Anthony, Kan.; died in the Marion County Hospital, Ocala, Fla., April 5, from cerebral hemorrhage.

George S. Rainey ⊕ Salem, Ill.; Louisville, Ky., Medical College, 1875; aged 69; a veteran of the Civil War; major and surgeon of U. S. Volunteers, during the war with Spain; died at his home, April 8.

Abram Eldridge Carpenter ⊕ Boonton, N. J.; University of Pennsylvania, Philadelphia, 1874; aged 66; a specialist in tuberculosis; mayor of Boonton in 1891; died at his home, April 8, from nephritis.

William Harris Pope, Jr., Beaumont, Texas; Tulane University, New Orleans, 1910; aged 33; a member of the State Medical Association of Texas; died at his home, April 12, from pneumonia.

John Wilson Burns, Watervliet, N. Y.; Albany (N. Y.) Medical College, 1901; aged 40; physician to the local tuberculosis dispensary; died at his home, March 29, from pneumonia.

James H. Holstein, New Orleans; Tulane University, New Orleans, 1899; aged 50; died at Touro Infirmary, New Orleans, April 9, a few hours after an operation for goiter.

Elmer Bert DeGraff, Alexandria, Minn.; College of Physicians and Surgeons, Keokuk, Iowa, 1888; aged 55; died at his home, April 1, from pneumonia following influenza.

Abraham Branaman, Kansas City, Mo.; Kansas City (Mo.) Medical College, 1899; aged 65; died in the Kansas City General Hospital, April 1, from cerebral hemorrhage.

Alphonse A. Clafflin, St. Albans, Vt.; University of Vermont, Burlington, 1890; aged 61; died at his home, January 16, from bronchopneumonia following influenza.

Yost S. Trayer, Denison, Texas; American Medical College, St. Louis, 1876; aged 69; died in a hospital in Sherman, Texas, April 4, from cerebral hemorrhage.

Patrick Francis Boyle ⊕ South Bethlehem, Pa.; Jefferson Medical College, 1902; aged 56; died in a church in South Bethlehem, March 30, from endocarditis.

Harry Mayfield, Ogden, Utah; McGill University, Montreal; aged 38; died in Salt Lake City, March 20, from an overdose of a narcotic poison.

Martha May Howells, Detroit; New York Medical College and Hospital for Women, New York City, 1878; aged 70; died at her home, April 2.

Samuel H. Green, Atlanta, Ga.; Atlanta (Ga.) Medical College, 1882; aged 53; died in a sanitarium in Atlanta, April 3, from heart disease.

Duane B. Miles, Cleveland (license, Ohio, 1896); aged 68; a practitioner for about forty years; died at his home, April 7.

William Gibson, Defiance, Ohio (license, Ohio, 1896); aged 78: died at his home, April 3.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

IODEX

At fairly frequent intervals physicians receive through the mail free samples of "Iodex," a black ointment sent out in small, circular aluminum boxes. Iodex is sold by Menley and James, Ltd., New York City, under the claim that it is a preparation of free iodin,[1] minus the objectionable features that go with free iodin. The preparation was examined in the A. M. A. Chemical Laboratory in 1915, and found practically devoid of free iodin. The laboratory also reported that when one or two grams of Iodex was rubbed on the skin of the forearm on several subjects and the urine collected and tested for iodin, the results were negative. This disproved the claim that "thirty minutes after inunction [with Iodex] iodin can be found in the urine."

The findings of the laboratory, which were summed up in a report (The Journal, June 19, 1915) of the Council on Pharmacy and Chemistry on Iodex, was essentially as follows:

> 1. The composition is incorrectly stated; the actual iodin content is only about half of that claimed.
> 2. The action of Iodex is *not* essentially that of free iodin, although that is the impression conveyed by the advertising.
> 3. The assertion that iodin may be found in the urine shortly after Iodex has been rubbed on the skin, has been experimentally disproved.

At the time the laboratory reported its findings, it pointed out the obvious contradiction in the claim that Iodex is not only an "effective free iodin application without drawbacks" but also a means of "really efficient external iodine therapy without stain or irritation." It is impossible to have free iodin present in sufficient quantities to be therapeutically efficient and not get skin-stains and irritation.

In a recent issue of the house organ, *Pharmacal Advance,* there was a large display advertisement of Iodex under the heading: "For Prophylaxis and to 'Double Cross' Disease," with the claims:

> "Free Iodine"
> "Rub Through Skin"
> "Does Not Irritate nor Stain"

On other pages of the same issue these claims appeared:

> "There is no therapeutic virtue in Iodex which is not inherent—though often latent—in Free Iodine; and there is no virtue in Free Iodine which is not available in Iodex."
>
> "In Iodex all the beneficent properties of Iodin are emphasized and all its disadvantages are eliminated—in a word, Iodex is Pure Free Iodin presented therapeutically active and efficient, ready for use in all conditions, with all the well-known powers of Free Iodin, but without the sequelæ of unpleasant effects, as irritation, corrosion, desquamation, staining, etc., which defeat the ends of treatment when ordinary preparations of Iodin are used. The fact that Free Iodin in the form of Iodex can now be used in rectal and vaginal treatment, without irritation, speaks volumes for its penetrability and bland action."

These quotations are sufficient to show that the manufacturers of Iodex still persist in their claim that the product contains free iodin. In view of this the A. M. A. Chemical Laboratory has again examined Iodex, having recently purchased specimens on the open market. It reports that Iodex gives no test for free iodin, or at most, but minute traces.

An interesting side-light on the methods of Menley and James is also brought out in the issue of *Pharmacal Advance* just quoted. Under a "department" misnamed "Book Reviews" the following appears:

---

[1] "Free" or elementary iodin (such as the tincture of iodin) is used externally for its local irritant and antiseptic effects. "Combined iodin," (*e. g.,* iodid of potassium) does not produce these effects and when preparations containing iodin in combined form are used, it is with the expectation of obtaining the systemic ("alterative") effects such as are produced by iodids.

> "The Actions of Drugs.—Torald Sollmann, M.D. Published by W. B. Saunders Co., Philadelphia. This is a book of lectures designed for students in pharmacy and deals with the subject in plain and simple language. The author in his introduction has brought out the fact that over-counter prescribing is baneful both to the public and to the pharmacist himself. Among some of the interesting points brought out that *Pharmacal Advance* has always maintained, namely, that 'Potassium iodid is not absorbed efficiently by the skin; hence the ointment of potassium iodid is unscientific.'
>
> "We would especially call attention to Ungt. Iodi U. S. P., containing Potassium Iodid, used as a solvent for its iodin content. Accepting Sollmann's statement, it is to be assumed that Ungt. Iodi U. S. P. has not 100 per cent. efficiency."

Garbling statements from scientific works for the purpose of puffing proprietaries is not unusual in nostrum exploitation. The facts are that the statement in Sollmann's book, introduced in the Menley and James house organ under the guise of a book review, appeared in a discussion of iodin compounds. In this the author points out that to obtain systemic iodid effects, it is irrational to apply iodin preparations externally. So far as the free-iodin content of the official ointment of iodin is concerned, L. E. Warren (Reports of the A. M. A. Chemical Laboratory, 1917) has shown that even after more than six months this ointment still contains about 75 per cent. of the free-iodin originally added. The official ointment (*Unguentum Iodi*, U. S. P.), therefore, so far as its free-iodin content is concerned, is far superior to Iodex, which contains no iodin in its free state.

TWO MISBRANDED NOSTRUMS

Bull's Herbs and Iron Compound.—Shipped in March, 1917, by the W. H. Bull Medicine Co., St. Louis. Analysis showed the preparation to be a weak alcoholic solution containing iron, phosphates, sugar and vegetable derivatives, among which were quinin, red pepper, gentian and podophyllum. Falsely and fraudulently represented as a remedy for weak nerves, ailments peculiar to women, scrofula, rickets, liver, kidney and bladder diseases, etc. Fine, $25 and costs.—[*Notice of Judgment No. 6215; issued April, 1919.*]

Effervescente Granulare.—Shipped in June, 1917, by the Milano Pharmacal Co., Inc., New York City. Analysis showed the preparation to consist of over 13 per cent. of baking soda, 61 per cent. of sugar, 3 per cent. of borax, and 17 per cent. of cream of tartar. The product was invoiced as "Eff. Magnesia," but the analysis showed there was no magnesia present. It was declared adulterated because of presence of borax, and misbranded because, while sold as Effervescent Magnesia, it contained no magnesia. Fine, $15.—[*Notice of Judgment No. 6221; issued April, 1919.*]

Correspondence

"THE SUPPLY OF PRACTICAL NURSES"

To the Editor:—I pointed out, in The Journal last year, the need of more nurses, of a class of women in that profession too little represented now, and of a shorter and better balanced training course. Since then, renewed criticisms of the old régime have appeared, culminating in your trenchant editorial of January 25 on "The Supply of Practical Nurses." And in recognition of these needs, the nursing situation is undergoing an evolution. Stanford University offers its college degree and nurse's diploma after three years in the university and two more in the hospital, and is also giving a preliminary course of intensive training for three months of an eight-hour day, at a fee of $90, to qualified young women, who must live at home. This aims to do three things: (1) Give training in sciences in a properly equipped school, thus enabling smaller schools to demand this prerequisite and devote themselves solely to the practical part of nurses' training; (2) establish the precedent of student-nurses living at home or in homes of their own choosing; (3) afford them an insight into the educative side of the work without the monotony and drudgery and endless repetition of menial tasks. Once show the highest type of women that the nurse's training may be an education and not a mindless, long-drawn-out vocational training, made bearable only by its emotional appeal, and we shall render as great a public service as was rendered when training schools were first established.

The Vassar Plattsburg for nurses was a frank attempt to attract educated women into the nursing profession. Findings in the occupational history of college women, published in the May, 1918, number of the *Collegiate Alumnae Journal*, are significant. Of 16,000 graduates of ten years' standing, 7,819 entered the profession of teaching; 471, the profession of social service; eighty-four, the profession of medicine, and thirty, the profession of nursing. Contrast this pitiful showing of college women in nursing with their response to the wartime appeal for nurses, which offered a distinctly educational program to begin with. The training camp for nurses at Vassar College cut down by nine months the three year course for all women of not over ten years' graduation time from recognized colleges. Over 1,000 applications were received; 435 applicants were carefully chosen, and given twelve weeks' intensive training under hospital régime and the same discipline off duty as prevails on any campus. Charges for the service were $95. Each of the 435 was placed under moral obligation to complete the training. No pledge was exacted to engage in nursing on graduation. Of the 435 entrants, 418 were graduated and 412 assigned to hospitals, 399 entering hospitals within a few months. The armistice naturally withdrew the big influence which led women into service, and yet the fact that up to Jan. 1, 1919, 104, or 25 per cent., had already withdrawn needs investigation. Inquiry reveals that 25 per cent. of these 104 resignations were due to the armistice; 15 per cent. more resigned to marry, and 4 per cent. to study medicine. Five died; three were rejected by the schools they entered; 289 still remain in hospitals. Twenty-one entered one of the best New York schools. Five dropped out before January 1, one to study medicine, one because of distaste for the work, and three because of illness. Sixteen are still in training, reported interested and satisfactory, though there is a general criticism of the monotony of work.

Plainly it was the desire for war service that brought college women into the nursing field. Without the urge and glamor of war, it offers, as at present taught, a too large proportion of mechanical tasks, destroying initiative and giving no scope for their trained resources commensurate with that in other professions.

The following data on nurses' training for war work was collected by the writer in France, and summarizes the opinions of hundreds of army physicians:

1. Wartime nursing was a new field, and nurses had much to learn.
2. Previous training and preconceived ideas were often a menace, instead of a help.
3. During drives, intelligence, willingness and strength determined usefulness, and no nursing training beyond ordinary ward experience was essential.
4. Shortage of nurses made refinement of nursing impossible. It was a new game under abnormal conditions which gave the fine type of nurses' aids a relatively greater advantage than they might have had under normal conditions.

The comparison at home presents a sad picture. The Journal editorial of January 25 accuses the trained nurse of bringing discredit on her profession which only the brilliant record of the service and sacrifice of her sister abroad can blot out. The charges of autocratic conduct, of unwillingness to meet home emergencies in the crises of illness, and of unwarranted demands for higher pay, should, as you point out, be limited to a small percentage of those who did not go overseas; but in this small percentage, the abuses of opportunity were so much worse than suggested by these criticisms that it must remain a reflection on all nurses if they do not themselves investigate and punish the flagrant defamers of their profession. The deduction is made that women of the right personality and native intelligence, preferably high school or college graduates, will after a year's training be fully as competent, in 90 per cent. of illnesses, as the three-year trained nurse, and fit into the average household better. The high-salary demand is the natural outcome of the absurdly long training period as compared with the short service later. Possibly the selfishness is a fatigue reaction to be overcome by an eight-hour day. Finally, personality and conduct are the resultant of heredity and the training begun a decade before the training school gets her. The corrective of bad breeding, lack of adaptability, and unwillingness to serve in emergencies, lies in a broader education, with less routine menial work, better home environment, and more inspiring and stimulating contacts.

Philip King Brown, M.D., San Francisco.

SUCCESSFUL HUMAN INOCULATION WITH PURE CULTURES OF PFEIFFER'S BACILLUS (B. INFLUENZAE)

To the Editor:—Some years ago when working with hemophilic bacilli from various respiratory infections, especially pertussis, I had occasion to test the pathogenicity of these organisms in the human throat. The result of this experiment was briefly recorded at the time in an article published under a general title (The Bacteriology of Whooping Cough, *J. Infect. Dis.* **3**:1, 1906), and for this reason might now be overlooked. Since the results were so striking, and in view of the importance of these bacilli in relation to the recent pandemic of influenza, I have been led, at the suggestion of several workers in this field, to record again the experiment under a more definite and pointed title.

The essential facts are these: Hemophilic bacilli were being found by me commonly in the throats and sputums of a number of infectious diseases, including pertussis, measles, varicella, bronchitis and many others, during interepidemic periods of influenza. They appeared all alike and had not at that time nor have they since been differentiated from the bacillus described by Pfeiffer (*B. influenzae*) as the cause of the influenza pandemic of 1889-1890.

Since these organisms revealed only slight pathogenic powers for animals and did not produce characteristic lesions in them, it was decided to test the effect of the bacilli on the human being. A young man, healthy in every way, volunteered and agreed to submit to the inoculation of his throat with pure cultures of the bacilli. Careful preliminary cultural examination of his throat revealed no bacilli of this character. He had not had pertussis, and according to his own statement and that of his relatives, had not had any serious illness. It is probable that he had never had true influenza, but this could *not be certainly determined.*

Typical blood agar pure cultures, twenty-four hours old, recently isolated from an uncomplicated case of pertussis were selected for the inoculation. They were washed off and suspended in salt solution, the growth from six tubes being used. I call special attention to this large dosage. The throat, tonsils and nasal mucosa were thoroughly smeared with this suspension, an ordinary throat swab being employed for this purpose. On the second day, almost forty-eight hours after the inoculation, the patient complained of a chilly sensation, a cold sweat, some headache and weakness. His temperature rose from normal (98.4 F. the day previous) to 100.2 F. The same evening it registered 100.1 F. The next morning it was normal again, but rose during the day to 99.5 F. The third day his temperature was practically normal and continued so from that time on. He complained somewhat of a headache and of feeling unwell, and on the second morning said he coughed a little. His throat, on examination when the first symptoms appeared, was slightly hyperemic; the next morning there was present a thick layer of mucus on the pharyngeal wall, and from this time on he coughed, or rather hacked up large quantities of a stringy, tenacious, slightly purulent mucus. This condition continued, becoming gradually less marked, but was still apparent at the end of four weeks. This cough was not spasmodic; it did not resemble pertussis. The leukocyte count on the second day was 9,200. Clinically there was little resemblance to influenza.

Bacteriologic examination of the mucus from the throat, obtained on the first day of symptoms, revealed almost a pure culture of the influenza-like bacilli. They were present both in the throat and on the nasal mucosa in enormous numbers. Direct smears of the expectorated mucoid sputum showed practically no other organism. They were identical in every detail with the organism inoculated. Examinations of the throat were made every few days for four weeks, after which time the patient was not accessible. The number of influenza organisms present became gradually less, but at the end of that time they were still present in considerable numbers. There were no complications.

This experiment shows that when Pfeiffer's bacillus is placed in the throat in large numbers it may grow for a long time and cause definite symptoms. These symptoms, however, do not indicate any specific infection; and this, it seems to me, is quite in accord with the fact that these bacilli are found so often in the throats of persons suffering with almost any respiratory infection. The experiment further shows that these bacilli are at least not always harmless saprophytes, and at times are capable of causing reactions which, though not specific in character, might modify secondarily a primary infection.

David J. Davis, M.D., Chicago.
Professor of Pathology, University of Illinois College of Medicine.

MUTUAL RECOGNITION OF MEDICAL DEGREES IN NORTH AND SOUTH AMERICA

(Translation)

To the Editor:—I have received the third number of the Spanish Edition of The Journal, and I have been most favorably impressed with its contents. It furnishes a most complete review of medical science, and gives a clear insight into the fraternal spirit which pervades the medical profession throughout the world. The world-wide scope of your publication gives it a position of advantage over local journals, especially over those whose main purpose seems to be the advertising of certain products.

Could you not inaugurate a movement which would include South America, Central America and North America, with the object of bringing about mutual recognition of medical degrees in all North and South American countries? The time has come when the reasons which may have existed in the past for national control of medical degrees no longer obtain, in view of the restricted privileges to which the holder of such degrees is entitled.

I base my opinion on the following considerations:

1. Medical science is universal.

2. The studies that constitute a medical course are practically identical everywhere, and the slight variations do not alter the basic scientific principles.

3. Physicians from all the American republics have exercised their profession with marked success on the battlefields and in the hospitals of Europe—is, then, their competence limited to war times?

4. There is reciprocity between several republics of South America: Argentina, Uruguay, Paraguay, Bolivia, Peru and Ecuador. Why not extend reciprocity to the other republics?

5. Physicians are especially fitted to give the highest expression to the fraternal spirit because of the peculiar character of their profession and owing to the fact that the medical works which they study in common constitute a strong natural bond.

6. The time is near when the medical profession throughout the world will be regarded by the various governments as an indispensable counselor. Why not let North and South America pave the way? Some common agreement must soon be reached with regard to the air, the water and the land, since micro-organisms are transmitted by these mediums. Then again, the medical profession of Pan-America must be the exponent of great social reforms, especially those of a humanitarian nature.

7. If preventive medicine and intellectual and social reciprocity are to rest on a solid foundation, it is essential that

mutual recognition of university degrees, especially medical degrees, shall be established without delay throughout Pan-America.

I invite your consideration of these ideas which I have jotted down as they occurred to me. It is my opinion that the American Medical Association is the body best fitted to launch this vast movement which will prove so eminently useful to the entire world. For this reason the physicians and the medical faculties of the United States ought to secure the opinion of their government, and if it approves the idea, an appeal should be made to each one of the American republics.

Why do we remain so distant? Why do we not know each other better, since a better acquaintance will promote the welfare of the countries in which we live and in which we are working to prevent and cure disease?

Dr. F. Vallés Vargas, Buenos Aires.

[Comment.—We are, of course, in sympathy with the lofty and far-reaching aims of our South American correspondent. It must be pointed out, however, that the goal he has in mind can be reached only by long and persistent labor, and that there are serious obstacles in the way. From our State Board Number, it will be seen that reciprocal relations are not yet an accomplished fact even among all the states in this country. In addition, before any such vast plan can be taken up, it will be necessary to have full information as to the character of medical education in all the countries involved, which may require an inspection of the medical schools, and some sort of uniformity established in the medical curriculums. With this end in view, the Council on Medical Education has been trying for some time to get data for Latin American countries similar to that now available for the United States. While this information has been forthcoming from some countries, it is still lacking for others; and we hope that the letter published above may serve to stimulate interest in this matter and make easier the collection of information on medical education in South America. The only countries from which such information has been received are Argentina, Bolivia, Brazil, Columbia, Mexico and San Salvador, and for some of these the information is quite incomplete.—Ed.]

PRAGUE FOR POSTGRADUATE MEDICAL EDUCATION

To the Editor:—Last January I wrote you from Prague, informing you that I had been located in France for six months, being associated with the Czecho-Slovak army, having charge of the American Red Cross Hospital in Cognac; also that early in January the convalescent men were ordered back to their homes in Prague, and that I was asked to accompany them.

After reaching Prague, I gave up my position in the hospital and assumed another duty, which I consider to be of great importance both to the United States and the Czecho-Slovak Republic, especially from the medical point of view.

I proposed to look into the possibility of organizing a clinic for the development of specialists at the University of Prague along lines similar to those formerly held in Vienna and Berlin; knowing that for some time to come the medical men from the United States would not be going back to these German cities.

The surgeon-general of the Czecho-Slovak government believed this to be a good idea and consequently ordered me on a "Special Mission" to the United States to invite medical men who desired to come to Prague to study and to explain what they had to offer.

Feeling that this matter could be enlarged on, I asked to be allowed to study the situation in the other allied countries and therefore made a trip to Italy (Rome), France (Paris and Lyon) and England (London). In these cities I studied carefully the possibilities of medical education and believe that in London is the future for such education abroad.

I hope I may have the opportunity of presenting the results of my investigations in these different cities, comparing them, one to the other, as well as all of them to our own postgraduate schools.

When I reached London, I examined The Journal at the library of the Royal Academy of Medicine, but found that the letter which I had sent from Prague had not appeared. Thinking that it might have been lost in the mails, I write this one, because I believe that the medical men in America are interested.

There are several men from America in Europe working along the same lines, among others Colonel Lloyd of New York, Capt. Lee Mastin Francis of Buffalo, also Dr. Franklin of London, England. In fact there are classes already doing good work, both in Paris and London.

Joseph E. Beck, M.D., Chicago.
Lieutenant-Colonel, Medical Corps, Czecho-Slovak Republic.

COMPULSORY DISPENSARY SERVICE

To the Editor:—Cooperation has become the watchword of our time. It might be considered by those who busy themselves particularly with the welfare of the people and of the medical profession, whether or not much good could be accomplished by obliging every physician in a community, whenever it can be done, to fill a hospital or dispensary appointment. This should not be a matter of privilege but a matter of duty. It would work out to the benefit of the public, as well as of the individual physician, who would enjoy a continuous postgraduate course. The details might be worked out by the American Medical Association. I respectfully submit this suggestion.

Emil Amberg, M.D., Detroit.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SIOMINE

To the Editor:—What, if any, advantages has siomine over potassium iodid?

H. F. W.

Answer.—The advantage claimed for siomine over sodium iodid is that it can be administered in solid form, thus avoiding the taste of iodids which it is claimed is sometimes responsible for nausea. The following statement of the action and uses of siomine appears in New and Nonofficial Remedies, 1919, p. 146:

> Siomine is decomposed in the intestine with formation of hexamethylenamine and iodide, the rate of absorption and excretion being essentially the same as that of inorganic iodides. It therefore produces the effects of ordinary iodides, from which it differs only in that it can be administered in solid form. The administration of siomine provokes the luetin reaction.
>
> No therapeutic claims are made for the hexamethylenamine component of siomine, this being present only to render the substance insoluble.
>
> While ordinarily the hexamethylenamine content of siomine may be ignored, the drug should be discontinued if any signs of hexamethylenamine intolerance should arise, such as vesical irritation or hematuria.

COLLOSOL MANGANESE

To the Editor:—Has anything been published on the efficacy of "Collosol Manganese" in malaria? I recently read the Council's report which indicated the fakishness of the "Crooke's Collosols," but I also was told that the War Office of England had requested a study to be made of colloidal manganese in malaria.

J. B., Columbus, Ohio.

Answer.—Stephens, Yorke, Blacklock, Macfie, Cooper and Carter report in the *Annals of Tropical Medicine and Parasitology* (Feb. 28, 1919, p. 345) the results of their investigation for the English government and conclude: "Collosol Manganese in the doses used is of no value in the treatment of simple tertian malaria."

COMING EXAMINATIONS

Arkansas: Little Rock, May 13. Sec. Eclectic Bd., Dr. C. E. Laws, 803½ Garrison Ave., Ft. Smith; Sec. Regular Bd., Dr. T. J. Stout, Brinkley.

Delaware: Wilmington, June 17-19. Sec., Dr. H. W. Briggs, 1026 Jackson St., Wilmington.

Florida: Jacksonville, June 16-17. Sec., Dr. W. M. Rowlett, Citizens Bank Bldg., Tampa.

Georgia: Atlanta and Augusta, June 5-6. Sec., Dr. C. T. Nolan, Marietta.

Hawaii: Honolulu, May 12. Sec., Dr. J. R. Judd, Beretania St., Honolulu.

Massachusetts: Boston, May 13-15. Sec., Dr. Walter P. Bowers, Room 501, No. 1 Beacon St., Boston.

Michigan: Ann Arbor, June 10-12. Sec., Dr. B. D. Harison, 504 Washington Arcade, Detroit.

Minnesota: Minneapolis, June 3-6. Sec., Dr. T. S. McDavitt, 741 Lowry Bldg., St. Paul.

Missouri: St. Louis, June 9-11. Sec., Dr. George H. Jones, State House, Jefferson City.

National Board of Medical Examiners: Philadelphia, June 2-7. Sec., Dr. J. S. Rodman, 1310 Medical Arts Bldg., Philadelphia.

Nevada: Carson City, May 5. Sec., Dr. S. L. Lee, Carson City.

New Jersey: Trenton, June 17-18. Sec., Dr. Alex. MacAlister, 438 E. State St., Trenton.

New York: Albany, Buffalo, New York and Syracuse, May 20-23. Mr. George M. Wiley, director, Exam. and Inspections Div., State Edu. Bldg., Albany.

Ohio: Columbus, June 3-6. Sec., Dr. H. M. Platter, State House, Columbus.

South Carolina: Columbia, June 10. Sec., Dr. A. Earle Boozer, 1806 Hampton St., Columbia.

Tennessee: Knoxville, Memphis and Nashville, June 13-14. Sec., Dr. A. B. De Loach, Exchange Bldg., Memphis.

Virginia: Richmond, June 17-20. Sec., Dr. J. W. Preston, 215 S. Jefferson St., Roanoke.

Vermont February Examination

Dr. W. Scott Nay, secretary of the Vermont State Board of Medical Registration, reports the oral, practical and written examination held at Burlington, Feb. 11-13, 1919. The examination covered 12 subjects and included 90 questions. An average of 75 per cent. was required to pass. Three candidates were examined, all of whom passed. One candidate was licensed by virtue of a commission in the Medical Corps. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Harvard University		(1911)	84.1
New York Homeo. Med. Coll. & Flower Hosp.		(1910)	86.1
University of Vermont		(1918)	88.1

College	LICENSED BY ENDORSEMENT OF CREDENTIALS	Year Grad.	Certificate from
Long Island College Hospital		(1894)	U. S. Army

Michigan February Examination

Dr. Beverly D. Harison, secretary of the Michigan State Board of Registraion in Medicine, reports the written examination held at Detroit, Feb. 19-20, 1919. The examination covered 14 subjects and included 100 questions. An average of 75 per cent. was required to pass. Twenty-five candidates were examined, all of whom passed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Detroit College of Medicine and Surgery		(1919)	76.3, 80.1, 81, 81.4, 81.7, 82, 82, 82.3, 82.9, 83.1, 83.7, 83.9, 84, 84.4, 84.6, 84.6, 84.6, 84.9, 84.9, 85.1 85.6, 86, 86.3, 86.9, 87.2.

Utah Reciprocity Report

Dr. G. F. Harding, secretary of the Utah State Board of Medical Examiners, reports that 6 candidates were licensed through reciprocity at the meeting held Jan. 6, 1919. The following colleges were represented:

College	LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
Chicago College of Medicine and Surgery		(1918)	Illinois
Rush Medical College		(1883)	Iowa
Indiana Medical College (Purdue Univ.)		(1906)	Indiana
Harvard University		(1916)	New York
Columbia University		(1918)	New York
Jefferson Medical College		(1898)	Penna.

Social Medicine, Medical Economics and Miscellany

THE PSYCHOLOGY OF PACIFISM

EDGAR JAMES SWIFT, PH.D.
Professor of Psychology and Education, Washington University
St. Louis

Crises reveal mental disorders that pass unnoticed in peaceful times. Through uneventful days the mind pursues its placid course, unchallenged. But when great questions stir the people and issues must be faced, then ability to see things in their right proportion is a rigorous test of sanity. "We are all mad, but I know it," Edward Fitzgerald once said, and perhaps the difference between those whose thinking is incurably "deranged" and others for whom the prognosis is favorable lies in just this knowledge of the waywardness of the human mind. None of us, probably, are hopelessly sane; but perfect assurance and complacency in the verity of one's beliefs greatly reduce the prospect of recovery.

Crises also disclose the content, or lack of content, of human minds. They compel men to find themselves. A great issue is an amazingly keen scout which searches the mind for hidden defects. It is like a chemical that forces precipitation. It analyzes human minds. "The moment when great spirits reveal themselves is when everything is lost."

When a comparatively small group asserts its wisdom against the nation, these men and women are either geniuses or they are suffering from disturbance of mental poise; and probably no one would be inclined to give pacifists the former distinction. What, then, is the explanation of their refusal to cooperate in a war that was so clearly a defense against future aggression? Why did men and women, some of whom are disconcertingly capable in other matters, stand in the track of a great national movement?

This question would not be worth asking did it relate merely to the crisis from which we have just emerged. The war is won. The hands of the clock always move forward. Pacifists were only specks of dust in the timepiece of civilization that made the winning of the war a little late. There is, however, danger of their obstructing the machinery of progress in other matters. Pacifists are not so much individuals as they are a state of mind. And this state of mind is worth examining because it has certain interesting psychologic features, and threatens social danger.

The instinct of self-abasement describes one class of pacifists, pacifists not merely in their attitude toward the war which has just ended, but toward all questions that threaten social or business interests, questions that imperil personal relations or preferment. These are the people who can never be induced to take a positive stand regarding matters that stir the community or the nation. Great ideas never grip them. They are incapable of tremendous enthusiasms. They may be convinced, but they request that their views be not made public. They cannot take a definite stand, and act.

Self-abasement is only a euphemistic way of putting an unlovely fact. Tell a man that he has the self-abasement attitude, and he will feel that you are complimenting him for his humility. Call him a coward, and the consequences will depend on the quantity of self-assertion combined with self-abasement in his personal formula.

Yet many of those who suffer from self-abasement are not conscious cowards. Indeed, they would indignantly deny the charge, and justly. For they find satisfying reasons for their failure to act. "The people are not ready," they say. "They must first be educated to our point of view." Or, "I can do so much more good in other ways if I do not arouse antagonism. My services are needed and I must not jeopardize my influence." Perhaps, indeed, the motive is more personal. "Taking a definite stand will injure my social, business or political prospects, and one must consider one's own interests."

The ingredient of egoism in all these excuses is obvious. And egoism, paradoxical as it may seem, is both recessive and projective—self-abasive and self-assertive. It is a curious psychologic fact that one does what one wishes to do, and then finds reasons to justify one's actions. Many conscientious persons are cowards, but their timidity, overlaid with good intentions, is hidden from themselves.

Human conduct, however, cannot be adequately described in a single formula. Behavior is too complex for so simple a solution. Self-abasement does not explain the attitude of a rather large and exceedingly conspicuous group of pacifists. It does not account for those who jeopardized their social or professional prospects by advocacy of peace. It does not interpret the determination of those who have gone to prison for their belief. With these people pacifism assumes all the intensity of religious fervor, and it displays this enthusiasm and propagandic zeal for exactly the same reason that prompted the self-immolation of religious martyrs—a psychoneurotic condition that finds the most exquisite joy in suffering for a principle. The mental "set" of these pacifists is strikingly similar to certain borderland cases of insanity—cases in which the ego is immensely exaggerated.

Let us clear the ground that we may get a better view of the nature and variety of mental derangement. First of all, insanity is not always the result of cerebral disintegration. To be sure, changes in nerve cells and centers doubtless occur, but so they do when we think, and it is often quite as impossible to detect alteration in the former case as in the latter. Insanity is sometimes the expression of a perverse relation between ideas, or the manifestation of a persistent thought or belief which has become fixed in the mind. In either case the result is a "deranged" mental condition.

This "derangement" may be slight and harmless. The man himself, quite likely, is fully aware of his "peculiarity." It may be one of the good stories which he relates about himself. This, in itself, separates him from the actually insane. Yet the distinction is one of degree rather than of kind. It is a quantitative and not a qualitative difference. The man, for example, who always fears lest he may not have locked his office or safe, and who repeatedly tries the door to assure himself that it is secure, differs only in the degree of his mental peculiarity from another who believes that he is persecuted. Repeatedly trying doors, or washing one's hands for fear of contamination, are harmless diversions. There is no reason why one should not entertain oneself in these ways if one gains comfort and pleasure from the act. In their more lucid moments these people are quite aware of the absurdity of their fears. But a man who persists in thinking himself persecuted may commit murder in the belief that he is protecting his own life.

We have said that insanity is a matter of degree. There is no line of demarcation that separates the sane from the insane. The extreme cases, of course, can be distinguished, but those on the borderline cannot be definitely classified. We call men "queer," "cranks," "peculiar" and "eccentric," but do not confine them in an asylum. Quite likely they would pay us the same compliment of being "a little off." Both wisdom and eccentricity depend on the point of view. An insane man in an asylum frequently regards every one except himself as insane. The verdict of "strange," or "unbalanced," however, is not necessarily a purely subjective judgment. Perhaps the test is the amount and persistence of deviation from the general, though not local, consensus of opinion. This test, as we have said, would at times include geniuses because the mass of people are conservative. The consensus of opinion is that of the "safe," "sane" men. And in this rather common use of the word "sane," the distinction of which we have been speaking is emphasized. One of the peculiarities of those confined in an asylum, however, is that there is no consensus of opinion.

The relation between ideas may be likened, somewhat roughly, to the arrangement of the furnishings of a room. The same articles may produce an interesting, harmonious effect, or they may cause a feeling of hideous discord. Now the distinction between the sane and the insane often lies in the arrangement of ideas, and in the manner in which they follow one another. This is illustrated by the occasional characterization of a man as of unusual sanity. We mean that his thoughts follow one another in a manner so reasonable and enlightening as to impress us with his "good sense."

Finally, we should remember that causation is as true in psychology as in physics or astronomy. Were it not so the mind would be a succession of chance thoughts and emotions, without any significance for the mentality of the individual. Thoughts follow one another for a definite reason. They obey the law of association as truly as objects left unsupported conform to the law of gravitation. A physical law is a statement of the unexceptional behavior, under definite conditions, of objects or forces in the world or universe. And, in like manner, a psychologic law describes the behavior of mental processes. In neither case does the so-called law give the reason for the behavior. It merely states the observed fact. Now the same law of association applies to the insane as to the sane. The difference is that in the insane the systems of thoughts are more perverse and fixed.

The law of association reduces finally to neural habit—the tendency of nervous impulses always to follow the path which they have taken before and, consequently, to bring the same thoughts into mind. One need not go beyond one's own circle of acquaintances for illustrations. Real thinking is sufficiently rare to be surprising and refreshing when encountered. Most people make essentially the same reply whenever the idea or word that commonly calls it forth is heard. And the reason for this is their organized systems of thoughts.

Every thought that comes into the mind has a reason for its existence. This reason is expressed in the law of association, and association, as we have said, is the outward manifestation of neural habit—the tendency of one nervous impulse always to bring certain other impulses in its train. The brain, and with it the mind, has been organized in this way by experience.

Nervous impulses form, as it were, closed circles. Within a given circle there is activity, but this activity does not arouse action beyond the circumference. These restricted nervous impulses combine into a nervous complex whose inbreeding activity produces a mental complex of ideas, thoughts and interpretations. Related experiences and knowledge thus become organized into a fixed system of thoughts and opinions which decide the outlook and view of the individual regarding all questions on which these thoughts have any bearing. The reply that such a person will make when his favorite or antagonistic topic is broached can be predicted. He cannot think beyond his mental complex. This is the explanation of prejudice. It is the cause of definitely settled opinions.

Every one, of course, has three mental complexes—organized systems of thought—but the distinction between "cranks" and "sane" people lies in the firmness of their hold. It is not uncommon, for example, to hear that a man is "crazy" about golf or photography. Appreciation of a book, again, depends on the mental complexes of the reader. Some one has remarked that Bacon was right in saying that reading maketh a full man; but what he will be full of depends on the man.

Pacifists do not differ from others in having these mental complexes. They are natural to the human mind. One of the characteristics of sanity, however, is the ability to let the mind play around ideas so as to see things in their right proportions. Pacifists assume that no moral achievement is worth a fight in which men may be killed. That the "right" not to fight was won solely because other men have fought for this freedom, does not enter into their thinking. This bit of history is not a part of their mental complex. Yet it is doubtful whether there is any good so unadulterated as to contain no dross. Now exaggeration of one evil so as to obscure others indicates a poorly balanced mind. And pacifists allow the evils of war—which all admit—to blind them to the good that a particular war may bring. To say that all wars are bad is to fail to make distinctions. No two situations are exactly alike, and the capacity to observe differences and apportion values is a test of intelligence, and of sanity.

One of the defects of thinking is that these mental complexes become, at times, so saturated with emotion that one is blind to distinctions. The mental complex then becomes a sentiment, impenetrable to argument. Phrases now answer for argument, and the mind is narcotized with "the rights of conscience," "the right of free speech," "the right to refuse to commit murder," and "the peculiar rights of those who have given their sincerest devotion to advocating the institution among men of that kind of livable régime by the very nature of which the present world calamity would have been rendered well-nigh unthinkable." The affection of pacifists for "rights" is charmingly naive to those who observe that it is always their own individual rights concerning which they are so solicitous. They are belligerent in defense of what they call the inalienable rights of man—by which they mean themselves—but unconcerned for the rights of the community and the nation when these rights conflict with their personal sentiments. They enjoy the results of the battles which others have waged in the past for liberty and democracy, but refuse service themselves. And it is this devotion to their personal rights which reveals their mental incompetence.

Emotions relating to the self are the most persistent and controlling in certain forms of loss of mental poise. This influence is especially likely to occur when one meditates long over matters that arouse apprehensive anguish. Gradually and insidiously, under these circumstances, egoistic emotions assert themselves until they pervade the entire content of the mind.

Now there is a group of pacifists in whom egoism has played a dominating rôle in the organization and fixing of their mental complexes. The members of this group have been conspicuous and influential because, in other matters, they have displayed ability, and some of them have achieved reputation. Indeed, it is largely because of the distinction which they have won that their thinking concerning the ethics of war has gone astray. Their emotions of self-esteem have become so swollen that they have obstructed the paths which nervous impulses underlying thinking must traverse. These people do not see enough in pacifism to puzzle them and stimulate reflection outside their organized systems of thoughts. In their placid self-assurance, the most complex problems with which the world was ever confronted are perfectly simple and clear. These pacifists bear with marvelous fortitude the threatened loss of all that past wars have won. And they face this prospect calmly because of the perfect confidence in their own judgment which self-esteem has imparted. They bathe in the waters of self-complacency and luxuriate in the delightful serenity that egotism imparts, and which causes one to feel that "the diviner part of one's nature is paramount."

Evidence of the exaggerated ego, which, at times, equals that of megalomaniacs, is given in the writings of some of these pacifists. We are informed, for example, by "Thirteen Conscientious Objectors and Their Champions," in one of our leading journals, that "in the evolution of the human mind we discover a gradually *widening* hiatus between physical competence and intellectual moral competence." And then the thirteen signers of this remarkable communication modestly admit, "We possess only intellectual and moral competence."

These same thirteen men apparently represent a distinctive class of humanists of unusual clarity of vision, whose wisdom society is in danger of losing. For, the communication continues: "The tremendous enterprise of recreating out of bloody *chaos some new*, reinspired internationalism will be the order of the day. Who is better fitted for that reconstructive task than those humanists now in imminent danger of being bullied out of existence because their visions and their faiths extend beyond the time of bloody chaos."

This peculiar, unappreciated "vision" is a common characteristic of those whose mental poise deviates slightly from normal sanity. The full current of self-esteem, which saturates their mental complexes, controls thought and action. Even one of the "sanest" of this class of pacifists, one of national reputation whose ability in social service is widely recognized, is convinced of the "spiritual worth" and clearer vision of the pacifists who, "seeing that which is invisible to the majority of his fellow men, still asserts his conviction and is ready to vindicate his spiritual value over against the world."

Vision, however, is not the only asset of these pacifists against the intellectual bankruptcy of the world. They alone keep their minds flexible, their reason clear and unprejudiced. "Is there no place left, then," one of their prominent writers cries, "for the intellectual who cannot yet crystallize, who does not dread suspense, and is not yet drugged with fatigue? . . . The intellectual who retains his animus against war will push out more boldly than ever to make his case solid against it. . . . His mind will continue to roam widely and ceaselessly. The thing he will fear most is premature crystallization."

This unclouded vision and uncrystallized mind of pacifists catches vistas of truth which the myopic and inflexible minds of less gifted "intellectuals" do not glimpse. Emotions which confuse the meagerly endowed do not distort the view of "ardent spirits, the lovers of mankind." This is obvious, since "an intellectual class that was wholly rational," as a writer of national reputation styles pacifists, would have accepted the plan of the pacifists and "called insistently for peace and not for war." To explain "the American intellectual" who "has been rational neither in his hindsight nor his foresight . . . we must look beneath the intellectual reasons to the emotional disposition. It is not so much what they thought as how they felt that explains our intellectual class."

Finally, these self-assertive pacifists have the same close communion with God and divine guidance that the German kaiser enjoyed, until the recent defeat of his armies. And they have the same inside information regarding divine approval of their plans. Since God agrees with them, his wisdom is clearly demonstrated, and all that is necessary is to accept his cooperation. A pacifist, writing in a prominent journal, and obviously quite familiar with God's views, puts the crucial question: "Have you the nerve to stand alone against the mob, to look sentimental savagery in the face and say No? Come on then. You who have the courage and the vision to be the cowards and fools of God—fall in!"

Intimacy with the Giver of wisdom, and possession of absolute truth, are fortunately claimed by few. If they were the majority, society would be a huge open air insane asylum with the sane minority doubtful of their own mental condition. "Cultivation will breed in any man a certainty of the uncertainty of his most assured convictions," Samuel Butler once said, and sanity is not less "sane" than culture.

Mental complexes every one has, and probably it is best that it is so. Social stability requires a certain consistency of belief. When, however, these complexes become isolated and rigid, the thoughts which they produce do not take account of varying circumstances. They are not affected by changed conditions. They do not see distinctions. Then, if in addition, thoughts and opinions are saturated with egoism, their possessor sees through glasses of complacency that distort historical and contemporary facts. These people, when opposed, believe themselves misunderstood and unappreciated, because self-esteem makes their beliefs the center from which truth radiates. Everything is wrong that does not coincide with their egoistic vision. "Considering myself as the instrument of the Lord, without being misled by the views and opinions of the day," the German kaiser once said, "I go my way alone for the prosperity and peaceful development of our fatherland." "Fall in," says the pacifist, "you who have the courage and the vision to be the cowards and fools of God." And the kaiser is known to be a megalomaniac.

The Medical Congresses at Rio de Janeiro

The *Revista Medica del Uruguay* gives an account of the Uruguayan delegation to the congresses at Rio de Janeiro which had to contend with the epidemic of influenza that prevailed in the city at the same time. The first ceremony was the inauguration of the new Facultad de Medicina, a splendid structure, only part of which is completed, but it is enough to house the medical school. Dr. A. de Castro related the history of the old and the new medical school, and the dean of the Montevideo Facultad de Medicina broached the project of the publication by all of a great practical manual of South American pathology, to be collaborated in by all the countries represented at the congress, the scientific institutions of Brazil to have charge of the organization of the necessary work. This project was officially approved later by the congress, the work to be known as the "Tratado de Patología Sudamericana." The inaugural meeting of the congress was held, October 12, in the Teatro Municipal, Prof. M. Couto presiding. The congress of dermatology and syphilography passed a resolution of congratulation and applause for Uruguay because it was the first country in South America to adopt prophylactic measures against venereal disease. At the concluding plenary session, a resolution was adopted calling for compulsory vaccination of cattle against anthrax in all the countries represented at the Conferencia de Higiene. Dr. Bachmann, the president of the Uruguayan delegation, invited the next congress to convene at Montevideo, and it was resolved that the committee of organization should be composed of the dean of the Montevideo faculty with the cooperation of the delegates there present. The tenth day after the arrival of the delegation a visit was paid to the Instituto Oswaldo Cruz which is in a suburb, about 20 kilometers from Rio de Janeiro. To one of the assistants, Dr. Machado, who was present, Dr. E. Espiro, in the name of the Consejo de Higiene of Montevideo, presented a tablet dedicated to the memory of Oswaldo Cruz. The festivities and banquets which had been planned for and by the visiting delegations were all abandoned on account of the epidemic.

New German Ordinances for Venereal Disease Control

The following is a translation of the text of two German ordinances with regard to venereal diseases recently published in the Medical Supplement compiled by the Medical Research Committee of Great Britain:

No. 6587. Ordinance for the combating of Venereal Diseases of Dec. 11, 1918. Reichsgesetzblatt, p. 1431.

For the purpose of combating venereal disease the following ordinance is issued:

No. 1. Syphilis, gonorrhea and chancre are venereal diseases within the meaning of this ordinance, irrespective of the question as to what parts of the body are affected by the symptoms of the disease.

No. 2. Any person suffering from a venereal disease in whose case the danger of his (or her) spreading the disease exists may be compulsorily subjected to medical treatment, and more particularly may be taken to a hospital, if this appears to be required, for the purpose of efficiently avoiding the propagation of the disease. Medical (or surgical) action involving serious danger to life or health is not permitted except with the patient's consent. The method for providing the expenses is determined by state law.

No. 3. Any person having sexual intercourse with another, notwithstanding the fact that he (or she) knows, or must assume in the circumstances, that he (or she) is suffering from an infectious venereal disease, is punishable with imprisonment for a period not exceeding three years, unless the general penal law (in view of the special facts of the case) imposes a heavier punishment.

So far as spouses or persons betrothed to one another are concerned, a prosecution is not to take place except on application (on the part of the aggrieved person). The prosecution is barred after the lapse of six months.

No. 4. Any one who medically examines or attends a person suffering from an infectious venereal disease shall give information to such person as to the nature and infecious characer of the disease, and as to the fact that the act referred to in No. 3 is a penal offense.

Berlin, Dec. 11, 1918. The Imperial Government,
Ebert, Haase.

The Secretary of State for the Interior,
Dr. Preuss.

No. 6589. Ordinance in respect of the care to be given to military persons suffering from venereal diseases of Dec. 17, 1918. Reichsgesetzblatt, p. 1433.

By virtue of the decree of the Council of Delegates of the People as to the formation of the Imperial Office for Economic Demobilization (Demobilization Office), dated Nov. 12, 1918 (Reichsgesetzblatt, p. 1304), the following ordinance is issued:

No. 1. (1) The name of any person discharged from the Army or Navy in whose case a venereal disease has been ascertained during the present war shall be notified by the competent military authority to the state establishment for national insurance in the district in which his new or last known place of residence is situated, in order that he may receive further medical care. Any person belonging to the Army or Navy who, without being formally discharged, remains absent from his unit is to be treated like a person discharged from the Army or Navy.

(2) The provision of subs (1) applies, *mutatis mutandis*, to any person who, during the present war, has stood in any relation of contract or service to the belligerent army, or has in any other manner remained with or followed such army.

No. 2. So far as the communications prescribed by No. 1 are not required on medical grounds, the administrative authorities of the Army or Navy may, subject to the consent of the Imperial National Insurance Office, refrain from making them.

No. 3. This ordinance comes into force on the date of its publication.

Berlin, Dec. 17, 1918.
Imperial Office for Economic Demobilization,
Koeth.

Book Notices

Principles and Practice of Infant Feeding. By Julius H. Hess, M.D., Major, M. R. C., U. S. Army, Active Service, Professor and Head of the Department of Pediatrics, University of Illinois College of Medicine. Cloth. Price, $2 net. Pp. 338, with illustrations. Philadelphia: F. A. Davis Company, 1918.

Infant feeding is of two types, natural and artificial. The tendency at the present time is to place the greatest stress on breast feeding and to offer artificial feeding as the logical second choice. Dr. Hess wisely uses almost one half of his book in discussing breast feeding. Although generally known to be the natural and ideal method for the infant, this subject has not received the attention in teaching which it has deserved. It is discussed here in great detail, the author considering explicitly all the possibilities and complications which may arise. He discusses maternal nursing and wet nursing in separate chapters, the latter being one of the most comprehensive that is available on this subject. In the section on artificial feeding the author does not adhere to any individualistic feeding method with fixed formulas; he is more concerned with the presentation of principles—adapting the food to the individuality of the infant rather than to that of the pediatrician. The fourth section concerns the nutritional disturbances. Outside of underfeeding, these are chiefly the idiosyncrasies of the infant to various individual constituents of its diet. The author is direct in his statements and his book will be found readily understandable by any physician who has the fundamental knowledge necessary to the modern practice of medicine. One of its most valuable features is an extensive appendix containing the formulas of the most widely known baby foods, directions for the preparation of various special mixtures and diets, a well illustrated article on the care of bottles and nipples, and numerous hints to answer the many questions with which mothers perplex the general practitioner. This is assuredly one of the most practical books available on infant feeding.

Principles of Bacteriology. By Arthur A. Eisenberg, A.B., M.D., Director of Laboratories, St. Vincent's Charity Hospital. Cloth. Price, $1.75. Pp. 198, with illustrations. St. Louis: C. V. Mosby Company, 1918.

It is difficult to write in an elementary manner and avoid loose statements. In trying to condense the subject of pathogenic bacteriology to 200 pages for the use of nurses in training, the author has at times not been able to circumvent this difficulty. In general, the material is well chosen for instructional purposes, but it would have been better to expand the discussions of the more common diseases and omit the rarer ones and the essentially animal infections. The paragraph on the paratyphoid group is certainly too brief, while symptomatic anthrax might have been left out. The four sentences on *Bacillus botulinus* do not give a correct impression. The chapters on bacteriologic technic contain well selected and adequate material.

Medicolegal

Delaying Too Long Sending Patient to Eye Specialist

(Beardsley v. Ewing et al. (N. D.), 168 N. W. R. 791)

The Supreme Court of North Dakota affirms a judgment in favor of the plaintiff for $7,933.50, for alleged negligence in the treatment of an injured eye, wherein it appeared that the patient should have been sent to an eye specialist at least twenty-four hours before he was. The court says that the plaintiff, while engaged at his occupation as an engineer, December 19, got a cinder in one of his eyes. At about 11 o'clock that night, after he had completed his run, he endeavored to remove the cinder by taking an ordinary match, burning the head off, and attempting to brush the cinder out with the charred end of the match stick. Failing in this, the next morning he went to the offices of the defendants, where the cinder was removed. His eye was not bandaged, and when the defendants offered him a prescription for a boric acid solution, he replied that he could get it himself without a prescription. On the day following he went again to the offices of the defendants. In treating the eye this time a bandage was applied and the plaintiff was given a prescription for a solution of argyrol. He returned at about 8 o'clock on the morning of the 22d, when he was told by one of the defendants that he should go at once to the head eye surgeon of the railway company in Minneapolis, where, at about noon of that day, the eye was promptly treated. The scar resulting from the operation, which was rendered necessary by the infection, was located directly over the pupil, and resulted in total blindness in the affected eye.

The principal error relied on for a reversal of the judgment was the refusal of the trial court to direct a verdict for the defendants, on the gound of the insufficiency of the evidence to establish the negligence of the defendants. There was considerable conflict in the testimony as to the time when the infection on the eyeball became visible; also as to whether or not the plaintiff had been advised early in the progress of the treatment that he should go to a specialist. So far, however, as the evidence on these matters might be regarded as having a bearing on the verdict of the jury, this court must, on this appeal, regard the plaintiff's version as being true. Moreover, it should be observed that the circumstances strongly supported his version as to the early appearance of the infection. Both the plaintiff and his wife testified that there was a small yellowish spot on the eyeball on the morning of the 21st, and both testified that one of the defendants stated on that morning that the eye was infected; that the defendant also wrote a letter, in the following May, to help out in an insurance matter, stating that the eye showed some infection, December 20. The Minneapolis specialist testified that the infection from which the plaintiff was suffering was in the nature of a hypopyon ulcer, or one which forms pus in the anterior chamber of the eye; that the development of an ulcer of the particular class to which this belonged is ordinarily very rapid; and that the proper course for a general practitioner, after infection has been discovered, is to send the patient to a specialist, unless the pactitioner has confidence enough in himself to take care of it. He also testified that a general practitioner would be treading on pretty dangerous ground in taking chances on the spread of an infection after an ulcer of the cornea has developed. Considering his testimony in the light of the facts, including the fact that the infection first appeared, not over the pupil of the eye, but a little below, the court is satisfied that there was evidence from which the jury was warranted in finding the defendants negligent in not using the proper treatment at the proper time. They were not protected by the rule, which they sought to invoke, that a physician is held only to the exercise of the skill and learning of the profession generally in the community in which he practices, because, according to their own testimony, they recognized the necessity of more expert treatment than general practitioners were capable of giving. Under the circumstances, the advice to go to a specialist should have been forthcoming at least twenty-four hours before it was given; and the proper degree of care was not exercised in prescribing only boric acid and argyrol, when the danger of the spread of such an infection and the inefficiency of such disinfectants were known.

The court also holds that a layman is competent to testify to the size of an abscess which can be observed with the naked eye; and that certain improper suggestions of liability insurance were not reversible errors.

Unsuccessful Treatment of Fracture Without Roentgenogram

(De Bruine v. Voskuil et al. (Wis.), 169 N. W. R. 288)

The Supreme Court of Wisconsin not only reverses a judgment for $1,800 damages obtained by the plaintiff for injuries alleged to have been sustained by reason of negligence on the part of the defendants in the treatment of a fracture of the tibia of the plaintiff's left leg about 2 inches below the knee, but remands the case with directions to dismiss the plaintiff's complaint on the merits. The court says that the plaintiff was a woman 49 years old. The accident occurred, November 5. The defendants reduced the fracture and placed it in a fracture box in the ordinary way with Buck's extension, attaching a weight of 26 pounds. December 20, defendant Voskuil removed the apparatus, a part of the weight having been taken off a week previously; and he attempted to ascertain whether or not union had taken place, but desisted on account of complaints made by the plaintiff. He advised her to use her leg. He called again, December 27, and then discovered that there was no union of the fragments. He then advised an operation for the purpose of fastening the ends of the bones together. The plaintiff was taken to a hospital in Sheboygan, where another surgeon performed an operation, ten weeks after which the plaintiff returned to her home, with the bone united perfectly, but her left ankle stiff. It was undisputed that prior to the operation there was never any exudate on the ends of the bones.

There was no evidence to show that the bones were not properly placed in apposition to each other, and there was no evidence to show that the weights were not properly attached in the usual and customary way. If an expert could not say that the treatment was improper, on what ground could the jury arrive at that conclusion? The fact being established that there was no union, it was assumed apparently that it must be due to some negligent treatment. The evidence did not sustain that view. The entire case here rested on the testimony of a physician to the effect that he would have treated the fracture in another way. Physicians are not compelled to choose at their peril between two accepted methods of treatment. Statements of experts that they would have treated the fracture in some other way are incompetent.

The trial court correctly instructed the jury that:

> A physician and surgeon is not an insurer or guarantor of a cure. If the treatment in this case was such as physicians or surgeons of ordinary knowledge and skill of the same school of medicine, and practicing in the same vicinity, would have exercised under the same or similar circumstances, then the fact that a bad result followed from the treatment, if you find that that was the fact, is not in itself alone sufficient to charge the defendants or either of them with negligence.

The difficulty seemed to be that the trial court entirely ignored the undisputed fact that the failure of the fragments to unite was due to some cause with which the treatment administered by the defendants had nothing whatever to do; that is, the failure of nature to set up the healing process.

But there was one claim of negligence as to which there was sufficient evidence to sustain the finding of the jury, and that was that defendant Voskuil was negligent in not discovering the fact that the injury had not healed at the time of the removal of the extension apparatus, and in the defendant's further failure to call on the patient for seven or eight days thereafter. However, there was no evidence showing that this in any way contributed to or was a factor in producing the injury complained of.

At the time of the plaintiff's injury there was no roentgenographic apparatus at or near the place where she lived, and there was no suitable electrical current available. Neither did it appear from the testimony that, had a roentgenogram been taken during the treatment, it would have shown that no callus was being formed at the point of fracture. Nor was there cited any case holding that it is as a matter of law negligence for an attending physician and surgeon to fail to avail himself of the use of a roentgenographic apparatus in the case of fracture, and on the facts shown here this court cannot so hold, particularly as it was comparatively easy to determine whether or not the ends of the bones were in apposition. It is clear that under the facts in this case the failure to procure a roentgenogram during the course of treatment did not amount to negligence or unskilful treatment.

Validity of Contract Not to Practice in County

(*Rowe v. Toon* (*Iowa*), *169 N. W. R. 38*)

The Supreme Court of Iowa, in affirming a decree enjoining the defendant from practicing medicine and surgery in a county from which he had agreed to retire from practice for a period of ten years, and relinquish his business to the plaintiff, for a consideration of $1,000, declares it cannot say as a matter of law that the restriction, either as to territory or to time, was unreasonable. It is not an unheard of or very unusual thing for a well-established physician of good repute to enjoy a practice coextensive with his county, and even a young physician, whose present practice is comparatively limited, both in the number of his patients and in the area in which he finds his patients, may yet reasonably hope, if well qualified, to extend his practice much beyond the immediate vicinity of his office or home. The contract sued on not being unreasonable on its face, the plaintiff was not required to negative the existence of possible conditions rendering it void or voidable.

The position could not be successfully maintained, which the defendant took, that, unless the seller is disposing of some tangible property, like an office or residence or stock of instruments, medicines or supplies, used by him in and about his business, there is nothing to support the ancillary agreement to retire from his practice in that neighborhood. It is too clear for argument that a person having an established practice as a lawyer or physician may sell his business, and by binding himself to refrain from all competition with his purchaser for a reasonable time, and within reasonable territorial limits, he can vest his purchaser with a valuable opportunity, and that such an agreement is not to be condemned or avoided as without consideration, or as being forbidden by any sound principle of public policy. True, the lawyer cannot (in this way) sell his clients, or the physician sell his patients or their individual patronage or their individual good will; yet he can, by such sale and by an honest observation of his covenant not to embarrass his purchaser by competition, confer on him a real advantage and hasten the acquisition of business by him on his own account, and the courts should be slow to establish any rule or precedent by which any person can make a pretense of such sale, and, having received the stipulated price therefor, immediately repudiate its obligation and take from his purchaser the sole and only consideration on which he parted with his money. Had the defendant remained in the county and withdrawn from practice therein as he agreed to do, the plaintiff would have had no ground for complaint.

Nor was the contract between the parties and the payment of money in pursuance of an unlawful conspiracy in restraint of trade, as was argued, because, when the plaintiff returned to complete the deal with the defendant two months after it was made, and found another physician had settled in the town, the agreement was modified or supplemented by one for a nominal partnership of the plaintiff with the defendant, and for the defendant to remain a while longer to introduce the plaintiff to the people and aid him in getting started.

Neither was there any merit in the defense that the plaintiff had never complied with the statutes of the state regulating the practice of medicine, and the court should deny him any relief, because he had mistakenly filed his certificate from the state board of medical examiners for record with the clerk of the court for that county, instead of with the recorder of the county. It might be that by such mistake, though committed without conscious wrong, the plaintiff technically became chargeable with a misdemeanor, and rendered himself unable to enforce by law the collection of fees earned before the mistake was corrected; but from the outset he possessed the right to correct the filing. It did not lie in the mouth of the defendant, having sold his practice and received his pay for it, to declare his contract void because the plaintiff, in entering on the practice so purchased, mistakenly filed his certificate in the wrong office.

As to the sale of a professional practice, attacked ethically, it is answered that, while there has been some apparent divergence, and perhaps there have been some inconsistencies, in the practical application of the rule to particular cases, there is no substantial conflict anywhere on the proposition that a professional practice is a lawful subject of sale, and that equity will protect the purchaser against the competition of a seller who has contracted to surrender the good will of his business to the buyer.

Unsuccessful Operation for Cataract

(*Curran v. Holt* (*Maine*), *104 Atl. R. 579*)

The Supreme Judicial Court of Maine overrules a judgment of nonsuit in this action against a surgeon for alleged malpractice in connection with an unsuccessful operation for cataract. The court says that the plaintiff was treated by the defendant from November, 1911, until January, 1913. Jan. 28, 1913, the defendant performed an operation for cataract on the plaintiff's right eye. The operation was not successful, and sight was not restored. As the left eye subsequently became involved from what was apparently sympathetic inflammation, the right eye was removed by the defendant, April 14, 1913. This removal, however, did not allay the trouble with the left eye, and, after further treatment for several months, vision in that eye was also lost. The plaintiff in his writ alleged many negligent acts on the part of the defendant, which he said might have produced the blindness. These he summarized in his brief as follows:

> Such as general negligence; that the incision on the eyeball of the right eye was within what is called the danger zone; that the defendant did not make a proper diagnosis of the eyes, and did not understand the real condition of the eyes before he operated; that he did not use proper methods in preparing the eye for the operations, and in treating the eyes before and after the operations of Jan. 28 and April 14, 1913.

The evidence introduced by the plaintiff, including that of an eye specialist, failed utterly to substantiate a single one of the many claims set forth in the writ. True, the operation proved unsuccessful, and on that fact alone the plaintiff seemed to rest his case. But that was not sufficient to establish negligence on the part of the operator. The surgeon cannot insure recovery, and the testimony showed that, with all due care, loss of sight results in 5 or 6 per cent. of the cases in operations for cataract, depending in large measure on the condition of the patient. It was shown here that the plaintiff's trouble was of long standing. His vision had been more or less affected for forty years.

It was not claimed that the defendant did not possess the ordinary skill of members of his profession in like situation. The law required him to exercise that ordinary skill, and to use reasonable care and diligence in his treatment of the case, and his best judgment in the application of that skill to the case in hand. The evidence did not show that the defendant failed to measure up to the legal requirement in a single particular, either in the care and treatment prior to the operations, in performing the operations, or in the care and treatment subsequent thereto. The defendant was not called on to offer any testimony. A jury would not have been justified in drawing from the evidence an inference of legal liability on the part of the defendant, and therefore the nonsuit was properly ordered by the presiding justice.

Blood Pressure in Shock.—Clinical and experimental studies have demonstrated that a systolic pressure of 90 mm. Hg is the limit of safety for individuals suffering from the the effects of shock if aggravated by hemorrhage. This complicating loss of blood must be assumed to have occurred in all wounded men showing the shock syndrome in order to give the maximum opportunity for recovery to reach individual.—*Review of War Surgery and Medicine.*

April, 1919, **48**, No. 3

*Plethysmographic Study of Shock and Stammering. S. D. Robbins, Cambridge, Mass.—p. 285.
*Intravascular Fat in Relation to Experimental Study of Fat Embolism in "Shell Shock". P. S. McKibben, Baltimore.—p. 331.
*Action of Potassium Cyanid on Oxygen Consumption. II. Action on Planaria. L. H. Hyman, Chicago.—p. 340.
*Effect of Cyanids on Carbon Dioxid Production and on Susceptibility to Lack of Oxygen in Planaria Dorotocephala. C. M. Child, Chicago.—p. 372.

Plethysmographic Study of Shock and Stammering.—Thirteen graduate students or college seniors and ten stammerers were the subjects in Robbins' experiments. He found that shock and stammering are accompanied in every case by marked vasoconstriction. In a few cases this is preceded by a short, inconspicuous rise in the plethysmogram which is probably caused by arm movement. Vasoconstriction does not begin until about three seconds after the stimulus is given. Long stimuli are accompanied by greater vasoconstriction and slower recovery than are short stimuli. Compound stimuli are accompanied by greater vasoconstriction and slower recovery than are either long or short stimuli. The more intense the stimulus and the more unexpected the stimulus, the greater is the vasoconstriction, the more rapid the vasoconstriction and the slower the recovery. All the tables show marked individual differences even on the same record. The greater the vasoconstriction, the more is verbal imagery impaired.

Those subjects who experience the greatest vasoconstriction during shock and stammering also require the longest time for recovery. Marked peripheral vasoconstriction takes place more rapidly than does slight vasoconstriction. Stammerers as a class experience slightly greater vasoconstriction in shock than in stammering. The time of recovery is practically the same in both stammering and in shock. Those subjects in whom the fear of stammering is pronounced, however, experience greater vasoconstriction and slower recovery in stammering than in shock. Vasoconstriction continues throughout the stammering interval; if any vasomotor change accompanies normal speech, it is vasodilatation in a large majority of periods. Therefore, Robbins concludes that stammering and shock are induced emotional disturbances accompanied by the same vasomotor changes. His experiments confirm Bluemel's theory that stammering is caused by transient auditory amnesia in the auditory speech center brought on by cerebral congestion.

Intravascular Fat in Experimental Shock.—Free fat droplets, stainable with sudan III, scharlach R or osmic acid were found by McKibben in the blood vessels of the brain, lungs and other organs of the dog and the rabbit in considerable number. In the cat, although present, this intravascular fat seemed to occur in smaller amount than in the dog or the rabbit. Observations on dogs indicated that there were no quantitative or qualitative differences between the fat, recognized histologically, in the vessels of normal control animals and that demonstrated in dogs subjected to concussion or prolonged anesthesia. In cats it seemed probable that a rich fat diet increased the incidence and amount of intravascular fat demonstrated histologically.

Action of Potassium Cyanid on Oxygen Consumption.—An extensive review of the literature on the chemical, physiologic and pharmacologic action of the cyanids is given by Hyman. All of this literature supports the generally accepted opinion that the cyanids depress physiologic processes in general, and rate of oxygen consumption in particular. A large number of experiments are reported which prove that the oxygen consumption is decreased in the presence of potassium cyanid. The amount of decrease depends on the concentration of the cyanid, ranging from 80 to 90 per cent. in 1/2,000 molecular potassium cyanid to 5 to 15 per cent. in 1/2,000,000 molecular solutions. The decrease is independent of muscular or ciliary activity. It is entirely reversible, the animals being wholly uninjured by the cyanid and returning to their normal rate of oxygen consumption when the cyanid is washed out of them.

Effect of Cyanids on Metabolism.—The results presented by Child are far less striking than Hyman's data on the effect of cyanids on oxygen consumption, and are regarded as merely supplementary to them. Hyman measured oxygen consumption in the presence of cyanids, while Child has been concerned almost wholly with what remains of the effect after return of the animals to water. While all the data agree as regards the effect of potassium cyanid, they permit only certain general conclusions concerning quantitative differences in susceptibility; but these, so far as they go, are in complete agreement with the conclusions drawn from experiments of other sorts. Since cyanids decrease both oxygen consumption and carbon dioxid production, Child believes that the increase by cyanid in susceptibility to lack of oxygen can mean only that cyanid and lack of oxygen are to some extent additive in their action on living protoplasm, that is, their action must be in certain respects identical or similar in character.

Epidemic Encephalitis with Stupor.—Kennedy has seen seven cases of this disease. In all, the diagnosis has been manifest. Stupor, however, varied in degree and was absent in one, a girl of 16; in her case there was the usual history of onset with headache, vertigo, and diplopia over about a week's time, together with at present third and seventh nerve palsies, much increase in tendon tone, and pronounced coarse tremor of the right extremities. Another patient, a man aged 35, has no emotional stupor, but lies curled up in bed complaining of headache. He is fretful and irritable. He vomits from time to time and presents inability to look above or below the horizontal and lacks the power of visual accommodation. Kennedy is convinced that these are cases of the same disease as was described by Economo in April, 1917, in Austria; by Netter a year later in France, and at the same time by various British observers in England.

Human Serum in Treatment of Influenza Bronchopneumonia.—Under the jurisdiction of the United States Naval Hospital at New York, 842 cases of pneumonia have been treated by Gould and others. Three hundred and twenty have come under Gould's immediate supervision at the Naval Hospital. The mortality rate among these 320 cases has been 26.16 per cent. Many of the patients were in an advanced stage of the disease or even in a moribund condition on arrival at the hospital. Thirty cases of so-called influenza pneumonia were treated by the use of human serum from convalescing patients with a loss of only two cases. The rapid and complete subsidence of symptoms unusual in most cases of influenza pneumonia gave hope that a specific line of treatment had been found. The author was able to confirm the contention of Redden that the amount of lung involvement in the donor is necessarily a reliable criterion in determining the value of his serum. He is impressed with the belief that the human serum from convalescent pneumonias undoubtedly contains valuable antibodies, and that its use in cases infected with homologous strains will give satisfactory results; but with the present limited ability to isolate the infecting organisms of the donor and the recipient, the method cannot yet be placed on a practical basis where definite results can reasonably be expected. Furthermore, this method cannot be used except in large, well equipped hospitals where access can be had to many willing donors.

Craniocerebral Roentgenogram Meter.—This craniocerebral roentgenogram meter, designed by Manning, is intended to be used on the heads of persons suffering from depressed fractures or in other suspected fracture cases, inclusive of foreign bodies or projectiles being received or lodged within the wall of the skull. The intent of the device is to aid surgeons who have to deal with these conditions with graphic landmarks on the head that will guide them more or less and assist in locating a foreign body after a roentgenogram is taken by approximating the different centers with which they may come in contact. The device is very simple in its application, being somewhat in the form of a chain cap with spiral springs attached at each junction of the chain in order that it may adapt itself to various sized craniums or heads. In the event of a hematoma existing, one half of the chain can be raised and the lines carried over from the remaining half in position on the other side of the head.

Case of Hysteria. J. L. DeCourcy, Cincinnati.—p. 287.

Fracture of Skull.—Emphasis is placed by Haines on some of the important signs of skull fracture. For instance: Some of the most extensive and fatal brain and cord lesions have followed injury wherein no fracture was found in the ward, by roentgen-ray examination or necropsy. Infinitely more will be accomplished for the patient by employing measures to relieve shock than by immediate operation, the one exception being the presence of active hemorrhage; and even here there is room for argument. Linear fractures of the skull with displacement should be placed under the caption of urgent surgery and dealt with accordingly. The dura is so closely attached to the bones at the base as to render fracture of the bone without rupture of this membrane almost impossible; and still such fractures *do occur*, and it is for this reason that one must be guarded in assigning a proper place to the absence of cerebrospinal fluid in the scheme of diagnosis. Escaping serum, following hemorrhage arising from uncomplicated rupture of the tympanic membrane or nasal mucosa, may present in mimicry of this system and lead to a grave error in the final conclusions. Notwithstanding the desperate conditions embodied in basilar fractures, about 50 per cent. of the patients, surviving the first forty-eight hours following receipt of the injury, make a final recovery. The treatment should be directed with a view of relieving shock, stopping hemorrhage, preventing infection, and controlling pressure.

Spray Solution for Acute Rhinitis.—The following spray solution is used by Thompson in cases of acute rhinitis:

atropin, ½ grain; epinephrin, 1 grain; menthol, 24 grains; camphor, 40 grains; oil sweet almonds, 2 ounces; liquid petrolatum, 6 ounces.

*Atropin and Dextrose Solution in Treatment of Acute Intestinal Obstruction. A. J. Caffrey, Milwaukee.—p. 447.

Digitalis in Cardiorenal Disturbances.—The intramuscular and intravenous routes of administration of digitalis are favored by Layton in the cardiorenal conditions, because these patients so often have not only a gastro-intestinal tract which renders absorption and time effect of the drug uncertain, but they frequently demand immediate results which can only be obtained by these routes, but the oral administation may be used as soon as conditions warrant it. The degree of hypertension present in no way contraindicates the use of digitalis if indicated. In fact, the hypertension is a compensatory process to be maintained temporarily, at least. If the heart needs digitalis, the existing hypertension may be disregarded.

Treatment of Acute Intestinal Obstruction.—Caffrey reports two cases in which very favorable results were obtained from the intravenous use of glucose solution.

Medical and Surgical Work as Prisoner of War.—MacDonald was taken prisoner by the Germans in March, 1918. In this paper he gives an account of his individual experience and the professional work of the German army surgeons.

Voluntary Muscle Response to Nerve Stimulus.—This paper is based on the result of tests made on many hundreds of wounded men, in the electricity departments of two of the largest military orthopedic hospitals. Levick found that after injury to a motor nerve the muscles supplied by the injured fibers respond to stimulus with a contraction longer in duration than that of the normal muscle. This was observed in every one of the many hundred cases tested. Levick suggests that this lengthening of the contraction is due to hyperexcitability in the muscle following a definite sequence of events. When the stimulus from the upper motor neuron weakens or ceases, the anterior horn cells of the lower neuron become hyperexcitable, and the muscle tone is increased. When the nerve impulse is slightly retarded, the muscle responds with a slightly lengthened response; when the nerve impulse is further retarded, the muscle responds with a further lengthening of the response; when the nerve retardation reaches a certain point, the muscle reaches a limit of response beyond which it cannot go, and this response is the same in cases of severe nerve compression or of complete division of the nerve. After suture of the nerve, and its subsequent regeneration, response to faradic stimulus first appears in the muscle, proving the dawn of a new nerve supply. Then, after a period the muscle begins to respond first with a slight shortening of the contraction, and then, following the gradual establishment of nerve influence, with a gradual further shortening until, following the complete regeneration of the nerve, the muscle response is restored once more to its normal length. When the excitability of a lower motor neuron is increased, that of the muscle is reduced.

Acute Rheumatism with Pericardial Exudation.—Poynton cites the case of a girl, aged 17, the victim of acute rheumatism, with a heart injured by a previous attack, who passed through a second most severe one while under observation in the hospital. A general pericarditis with copious effusion developed, and the fluid withdrawn by paracentesis showed numerous minute diplococci, some in the fluid, many more carried up in numbers by the polymorphonuclear leukocytes. The stage of the illness was one in which the acute phase was subsiding, but death was threatened from mechanical embarrassment. This patient did not die, the effusion did not return, the temperature fell, and eventually the recovery was so good that she left the hospital able to walk short distance, and with a compensated mitral lesion. This is the first case in which Poynton has been fortunate enough to obtain a living pericardial exudation in man in this particular phase, and it completely supports the results of experimentation. This result also serves to strengthen the extreme probability that in the human cases of rheumatic pericarditis in which there is little effusion but great thickening of pericardial tissues, the diplococci are shut in the necrotic areas but imperfectly destroyed; and, lurking there, flare up into virulence from time to time, and thus cause the intractable relapsing examples encountered in childhood.

Primary Sarcoma of Prostate in Boy.—The patient in this case was only 3½ years of age. He had had difficulty and pain on passing water for seven weeks, and had very frequently needed a catheter. At operation it was seen that the prostatic urethra was occupied by a tumor the size of a golf ball, which was easily shelled out. The tumor had the structure of a sarcoma. The child recovered from the operation, and was much more comfortable for some weeks, but recurrence was rapid, and death resulted.

*Observations on Babes-Ernst's Bodies and Formation of Spores. J. Ishiguro.—p. 1.
*Causes of Contamination of Air in War Vessels. R. Kimura.—p. 3.
*Lipovaccine. B. Abe.—p. 4.
Secretory Process of Urea and Chlorin Compounds by the Kidneys. G. Ezure.—p. 6.
*Quantity of Cholesterin in Blood. J. Yamakoshi.—p. 7.

Observations on Babes-Ernst's Body and Formation of Spores.—The protoplasm of the seventeen species of micro-organisms used by Ishiguro, with the exception of the tubercle bacillus, was promptly dissolved in concentrated phenol solution, thus leaving the microbic bodies staining faintly, or not at all, and the Babes-Ernst's bodies staining deeply at each pole of the microbe by the usual stains. Ishiguro claims that the intimate relation of this body to the formation of spores cannot be doubted. This body disappeared entirely after coming in contact with the spore corpuscle; but the difference of these two bodies—Babes-Ernst's body and spore corpuscle—could easily be demonstrated by the fact that the former had always some connection with the capsule, while the latter had none. The spore corpuscle, after uniting with the Babes body, underwent several changes, thereby becoming larger in its size, until a complete spore was formed, which first showed some remnants of the mother micro-organism, attached to both poles, to become ultimately free after these melted away.

Causes of Contamination of Air in War Vessels.—Kimura made experiments to determine the degree of contamination of the air caused by vegetables, coals and briquettes kept under conditions likely to exist in storing them in war vessels. Vegetables, such as turnips, onions, potatoes and Japanese onions, were stored separately in glass vessels kept in a cold dark place, and the air in each vessel was examined, after the lapse of a certain time, as to its degree of contamination, with special reference to its proportion of oxygen and carbon dioxid, by various methods, including chemical analysis and animal experiments. From the chemical analysis it was shown that potatoes for 1,000 men a day (488 grams of vegetables is given to one man as ration in the Japanese navy), when kept in a space with the volume of 18 cubic meters (a storage for example, of 3 meters by 3 meters by 2 meters), contaminate the air in that space to such a degree as to increase the proportion of carbon dioxid up to nearly 0.2 per cent., after one day, while this increase was about 1 per cent. in the case of Japanese onions stored under the same condition for the same length of time.

Typhoid Lipovaccine.—Typhoid lipovaccine prepared with unheated sweet oil was used by Abe and his co-workers for their animal experiments, and its value as a vaccine was compared with that of normal typhoid vaccine. They found that the toxin of typhoid bacilli in this lipovaccine was reduced to one fifth of the bacilli in the normal vaccine, and consequently a large dose could be inoculated at one time without any serious reactions. The agglutinin in the serum of rabbits inoculated with this vaccine appeared on the fourth day and reached its maximum value on the fifteenth day on the average. Its first appearance and when it reached its maximum were a little later than in the case when the normal vaccine containing the same dose of bacilli was inoculated at one time, but they appeared much earlier than in the case when the normal vaccine with the same dose of the bacilli was divided into three inoculations with a regular interval. This agglutinating power diminished slowly and became almost stable at the end of a period of about seventy-five days, and continued, after that time, to be almost at the same level for a considerable time. The relative strength of this stable value to the normal agglutinating power was much higher than in the case when the normal vaccine was used. The fluctuation of the value of the bacteriolysin followed almost the same line as the agglutinin, and its existence was much longer than in the case of the normal vaccine. The complement binding substance existed also for a long time. The protecting power of guinea-pigs against infection reached its maximum about ten days later as compared with the normal vaccine, but its standard was higher and maintained for a longer time. From these facts Abe concludes that, by the use of this lipovaccine, a larger dose of typhoid bacilli can be inoculated at one time with slight reactions, the trouble of inoculating repeatedly with the normal vaccine may be removed, and yet the acquisition of high and lasting immunity against typhoid may be attained.

Quantity of Cholesterin in Blood.—The quantity of cholesterin in the blood of ten healthy persons belonging to the laboring class in Japan varied between 130 and 160 mg. in each 100 c.c. of blood plasma, the average being 143 gm. This quantity was generally, though not constantly, lower in the blood of forty invalids suffering from beriberi, and also in cases of anemia and syphilis; while it was higher in three cases of hemiplegia. There was no marked difference in this quantity either before or after a meal.

Causation and Prevention of Industrial Accidents.—Every year, more than 1,000 workers (exclusive of miners) are killed in industrial accidents in England, from 100,000 to 200,000 suffer injuries sufficient to incapacitate them for a week or more, and about 2,000,000 suffer minor injuries. Vernon examined the accident records in four large ammunition factories over periods of from nine to twenty-five and one-half months, and more than 50,000 accidents were tabulated. Three fourths of the accidents were cuts, chiefly of the hands, against the sharp lathe tools and drills. In the afternoon spell the accidents were 29 per cent. more numerous than in the morning spell, and they were more than twice as numerour in the twelve-hour day period as in the ten-hour-day period. The rise of accidents in the morning is due partly to increasing speed of production. More important than speed of production is the effect of carelessness and inattention. When the average sobriety of the nation greatly increased because of increasing restrictions on the sale of alcoholic liquids, both men and women showed a steady dimunition in accidents. Unsuitable temperature is a very important cause of accidents. In a not very efficiently warmed shell factory the accidents to women were two and one-half times more numerous on such days as the external temperature was at or below the freezing point than when it was 48 F. or over, while at intermediate temperatures the accidents were intermediate in number. The accidents to men were similarly affected, and were twice as numerous on the very cold days as on the warm ones. Only one class of accidents was found to increase much by night, namely, foreign bodies (as metal or emery) in the eye. At the best lit factory they showed very little excess. For the prevention of accidents the author commends the methods employed in the "safety campaign," adopted in the United States. This consists in the installation of safety devices and of as complete a system of mechanical safeguards as possible.

Left Scapular Pain in Heart Disease.—Certain soldiers sent to a heart section complaining of pain below the left breast also spoke of pain in the back. Parkinson and others then began an investigation. In a consecutive series of 100 patients complaining of pain on the left side of the chest, twenty-eight complained also of pain in the left scapular region. The patient complains of pain "in the heart" and "going through to the back," or pain at the heart and "under the shoulder-blade." The scapular pain does not seem to occur in the absence of submammary pain. The pain may be sharp and stabbing, or it may be dull and aching; usually it partakes of the same characters as accompany the submammary pain, although it is rarely so severe. Some patients talk of a stabbing pain going through to the back, and some of an aching pain going round to the back. Exertion is by far the commonest exciting cause. The onset of scapular pain is gradual, and the course chronic. The most constant symptom associated with the thoracic pain is shortness of breath, also dependent on exertion; and it was present in all but two cases. In most it preceded the onset of pain; otherwise it became noticeable about the same time. Other frequent symptoms were palpitation, dizziness, and general weakness.

Of the twenty-eight men who complained of pain in the left scapular region, ten showed hyperalgesia on the posterior surface of the chest, involving in every case the lower part of the scapula, though sometimes extending far beyond it. Chronic pain below the left breast, and pain at or about the lower angle of the left scapula, are seen in valvular disease of the heart, myocardial disease, and in arteriosclerosis and chronic nephritis when the heart has become burdened. It occurs in functional heart disease if that term is used widely to embrace cases with cardiac symptoms and without abnormal physical signs connoting organic disease. Among such include those presenting tachycardia only, and those with added symptoms or signs indicative of functional nervous disorder in association. The history of rheumatic fever was given in twenty out of fifty cases. Of these, ten proved to have signs of valvular disease. Only two men gave a history of syphilis. Two dated their pain from scarlet fever, two from pneumonia, and two from trench fever; none ascribed the onset to pleurisy.

The abnormal signs noted among the fifty cases with scapular pain were as follows: Two had rheumatic valvular disease of the heart—namely, six, aortic incompetence; two, mitral stenosis, and two, mitral incompetence. One patient had breathlessness and pain in the chest and left arm so severe that the diagnosis of myocardial disease was made. Six had a high systolic blood pressure, over 150 mm. of mercury at repeated examinations, and one of these showed enlargement of the heart with a blood pressure of 210; another had very thick and tortuous arteries, and his blood gave a positive Wassermann reaction. In eight cases there was tachycardia, the pulse rate in recumbency being 100 or more at repeated examinations. Four men were nervous in their manner, two of these were tremulous, and a third had a typical hysterical seizure under subsequent observation. One man had persistent slight albuminuria with a normal blood pressure.

Autumn Influenza Epidemic in New Zealand Expeditionary Force.—The total results obtained by Eyre and Lowe in this study favor the use of their mixed catarrhal vaccine. Out of a total average strength of 21,759, approximately 16,104 men received full prophylactic vaccination, and approximately 5,700 were uninoculated or had received only one dose of mixed catarrhal vaccine. Out of a total average strength of 21,759, there occurred 3,366 cases of influenza (15 per cent.). Infection incidence in inoculated and uninoculated men is approximately in the proportion of 1.3 per cent. to 4.1 per cent. (or 1:3). The risk of death in severe and complicated cases in inoculated and uninoculated men is approximately as 8 per cent. to 23 per cent. (or 1:3). The risk of death among all cases infected varies for the inoculated and uninoculated as 0.26 per cent. to 2.2 per cent. (or 1:9).

Treatment of Complicated Influenza.—From a survey of Eagleton and Butcher's results, it appears that although inoculation by a mixed vaccine of *B. influenzae*, pneumococcus, streptococcus, *Staphylococcus aureus*, *M. catarrhalis*, *B. pneumoniae*, and *B. septicus* conferred no immunity to serious complications, yet the course of the disease was modified so that a lower mortality resulted in these severe cases.

Polyorrhomenitis: Malignant Serositis.—Cooke reports the case of a Turkish soldier, aged 29, who complained of malaise, slight cough, and pains in the back and the sides of the chest. He had had no previous illness, and was always able to perform his duties. There was no family history of tuberculosis nor evidence of syphilis. The temperature was 98 F., the respirations 20 with slight dyspnea, and the pulse 88, of good volume and tension. The patient was slightly cyanosed; the venules of the cheeks were prominent; the conjunctivae had a subicteral tinge. There was marked epigastric pulsation. Hypertrophic pulmonary arthropathy was marked in the hands. Diastolic collapse of the cervical veins was not present; there was no paradoxical pulse. Examination of the lungs revealed the chest expansion equal but poor. Litten's sign was absent. Vocal fremitus was very much diminished over both sides of the chest. The percussion note was much impaired; in no region was there absolute flatness. On auscultation the breath sounds were faintly heard over the lower three fourths of the chest. At the apexes in front the breath sounds were more audible. Expiration was prolonged over the whole chest; at the bases there were a few moist râles. Creaks were heard all over the chest. The sputum was scanty and mucopurulent. No tubercle bacilli were found; pneumococci were present in abundance. When the heart was examined the apex impulse could not be seen; there was marked epigastric pulsation; the cervical veins were not prominent. By palpation a diffuse, very faint systolic impulse could be detected in the fourth and fifth interspaces, inside the nipple line. Percussion disclosed an area of dulness from 2 inches on the right of the sternum to 4 inches on the left, at the level of the fourth interspace. The dulness extended upward to the sternal notch, and laterally blended with impaired resonance over the lungs. On auscultation, the heart sounds were faintly heard at the apex. The pulmonic second sound was very loud compared with the aortic. There were crackling râles over the whole of the sternum and the adjacent chest wall. The liver extended an inch below the costal margin; there was no ascites. The specific gravity of the urine was 1,018; there was no albumin nor sugar. The patient died with all the signs of edema of the lungs. A full necropsy report is given.

Retrospect of Otology, 1918. M. Yearsley.—p. 215.
*Treatment of Asthma. R. Stewart.—p. 218.
Anxiety State—Aspect of Treatment. L. Scott.—p. 222.

Diagnosis Between Organic and Functional Anesthesia.—Williamson points out that the greatest difficulty in diagnosis between organic and functional anesthesia occurs when only part of one or two limbs is anesthetic, as the hand and a portion of the arm, or the foot and a portion of the leg, the upper limit of anesthesia forming a line more or less at right angles to the long axis of the limb. This anesthesia may be functional or may be due to an organic cerebral lesion or multiple peripheral neuritis, but only in very rare instances to an organic spinal lesion (as syringomyelia or hemorrhage). If the upper limit of the anesthesia is very sharply defined, this is a point in favor of functional anesthesia. Often diagnosis is definitely decided by Janet's test, or by the vibrating sensation, or by other characters.

Diagnosis of Myocardial Debility by Means of Differential Stethoscope.—It is maintained by those who have used this instrument that it enables the physician to diagnoses myocardial changes. Thorne believes this to be the case, and offers confirmatory evidence in support of this statement. He has found the instrument of great value in judging the effect of acute febrile conditions, such as influenza, pneumonia, measles, acute rheumatism, pleurisy, bronchitis, and other illnesses, on the myocardium. The results obtained enable the progress of the disease in the acute stage and during convalescence to be estimated, and the patient to be kept in bed as long as there is any evidence of myocardial weakness. He has also found the differential stethoscope of great value in detecting malingerers who plead heart weakness, palpitation and breathlessness, when they do not wish to return to duty. Experience leads Thorne to believe that it can be relied on in the diagnosis of such cases.

Effects of Moderate Exercise on Blood Pressure.—One hundred officers cadets were used by Smythe to get these data. He found that in the majority of cases, the systolic blood pressure is lowered after moderate exercise. This lowering is caused mainly by the dilatation of the arteries and capillaries, and not by fatigue of the heart muscle. The average pulse rate in the series was 78 per minute, both before and after exercise. The effects of moderate exercise on the system are beneficial, as the peripheral dilatation caused thereby increases the warmth of the skin, and provokes the flow of sweat from the sweat glands without taxing the heart to any degree. After physical training on Swedish lines, the man finishes up unexhausted and fresh.

Treatment of Asthma.—Besides advising fresh air and proper diet and hygiene, Stewart gives iodids and arsenic with strychnin for one month after the attack has subsided.

*Paralysis of the Neck. F. Figueira.—p. 113.
*Cerebrospinal Fragility. A. Collin and Verdé.—p. 126.
*Latent Purulent Pleurisy in Young Children. P. Bézy and F. Escande.—p. 137.
*Neuroblastoma Sympathicum. J. Comby.—p. 142.

Paralysis of the Neck.—Figueira here presents six cases of the "cephaloplegic syndrome" which affects infants and young children, mostly previously healthy. On waking in the morning it is found that the head cannot be held up; it lops forward or backward. In some of the cases there had been a preceding pseudogrippal catarrhal affection. The tendon reflexes were usually attenuated, and in most of the cases the electric excitability was reduced. This acute and sudden akinesia disappeared in four to ten days, without leaving a trace. All the cases were observed at Rio de Janeiro, and the first coincided with an epidemic of 100 cases of poliomyelitis (1910-1911). Since that time, about ten or fifteen cases of poliomyelitis have been reported there each year. Figueira is inclined to regard the "cephaloplegic syndrome" as an abortive form of poliomyelitis, notwithstanding the lack of an epidemic and the absence of several symptoms usually regarded as testifying to poliomyelitis.

Vulnerable Nervous System in Children.—Collin and Verdé expatiate on the peculiar fragility of the cerebrospinal nervous system in some children, which renders it exceptionally susceptible to toxic and infectious influences. They review in detail the whole train of nervous phenomena which can be attributed to this. A long walk or muscular fatigue, long studying, may transiently modify the reflexes and sensibility. Sleep may be irregular or excessive, and the susceptibility to intoxications and infections is extreme. In young infants, spasmophilia, periods of agitation, and bradycardia when they are hungry are evidently due to the substandard state of their nervous system. Sometimes the differing electric responses on the two sides enable this special fragility on one side to be studied most instructively, as Moll has described in his work on the difference between the left and the right sides. He declared that the weaker side is more susceptible to morbid processes.

Purulent Pleurisy in Young Children.—Bézy and Escande explain the blunder in diagnosis in the two cases described as due to the remarkable tolerance of the pleura and lung for several months to the presence of and the pressure from the pus. The negative results of puncture must have been due to the thick consistency of the pus or to obstruction of the needle. The misleading resonance in the space of Traube was explained by radioscopy showing an unusually large air bubble in the stomach. Deviation of the heart and mediastinum is the most instructive finding. The boy of 3 was given operative treatment for a supposed osteitic process in the ribs. Radiography may be the only means to detect these latent pleurisies.

Neuroblastoma.—Comby summarizes recent literature on neuroblastoma sympathicum, and remarks that probably certain cases described as sarcomas of the suprarenals were in reality such neuroblastomas originating in the sympathetic nerve.

The Problem of Chemotherapy of Tuberculosis. L. Rénon.—p. 254.
Methylene Blue in Influenza. Blum.—p. 256.

Hot Air in Treatment of Wounds.—Vignat uses a jet of hot air or hot oxygen in treatment of wounds, and extols the fine results realized. It proved particularly useful in recent wounds, after clearing out the devitalized tissue, to ward off infection.

Demineralization of Bone.—Robin declares that all empiric measures have failed to arrest the demineralization of bone which has proved a serious complication with many war wounds, as well as in osteomalacia, etc. He outlines a course of treatment which has proved successful in his hands, as he describes in detail. The food must be selected to supply mineral salts, the generation of acids must be prevented, the nervous system stimulated, and cod liver oil and arsenical preparations given, with extra care for hygiene. The examples he gives show that this tendency to demineralization is not beyond our therapeutic resources guided by the metabolic findings.

Bulletins de la Société Médicale des Hôpitaux, Paris

*Streptococcus Septicemia. F. Rathery and J. du Castel.—p. 27.
Functional Tests of Heart in Secondary Syphilis. J. du Castel.—p. 31.
*Curable Cirrhosis of the Liver. Courtois-Suffit and R. Giroux.—p. 35.
Congenital Stenosis of Left Subclavian Artery. C. Laubry and C. Esmein.—p. 40.
*Meningococcus Septicemia. G. Faroy and E. May.—p. 44.
*Spirochetes in the Urine in Syphilis. P. P. Lévy and Guilé.—p. 48.

Streptococcus Septicemia.—Rathery and Castel report two rapidly fatal cases in healthy young soldiers. The onset suggested influenza in one case; in the other there was a typhoidal condition with generalized contracture, a papulohemorrhagic eruption with phlyctenas, and fulminating bronchopneumonia with rapid purulent breaking down of lung tissue.

Cirrhosis of Liver with Ascites, Peritonitis, and Recovery.—Courtois-Suffit emphasizes anew that a possible syphilitic origin should be suspected, until disproved, in every case of cirrhosis of the liver, even with ascites and even when there is alcoholism besides. Four typical cases are reported in which vigorous treatment based on the positive Wassermann reaction has apparently cured the patients. Even with a negative Wassermann, this treatment should be given a trial; the patient can only gain thereby. The improvement may be extremely slow and gradual; several months should be allowed to elapse before deciding that it is not effectual. In three other cases the debility was so extreme that the patients died before the specific treatment had modified the clinical picture.

Meningococcus Septicemia.—Faroy and May say that there was no meningitis and only arthritis with the meningococcus septicemia. Both the men recovered under intravenous antimeningococcus serotherapy. Injection of the antiserum into the joint did not seem to benefit, but the arthritis yielded promptly to an injection of ether. The septicemia had induced a typhoidal continuous fever.

Spirochetes in the Urine.—Lévy and Guilé examined the urine of twenty-four men shortly before or after the beginning of the secondary stage of syphilis. The pale spirochete was found in the urine in only one of the men, and this only at the end of the first month after the development of the chancre.

Lyon Médical

March, 1919, **128**, No. 3

*Treatment of War Aphonia. J. Garel.—p. 129.
Polyvalent Serotherapy in Influenza. R. Pauly.—p. 170.

War Aphonia.—Before the war, Garel had scarcely ever encountered aphonia in men, although it has always been comparatively common in women. The emotional stress of warfare caused the development of aphonia in many of the men on active service. He has had 196 cases, and thirty-eight of the men had had the aphonia from six months to three years. A complete cure was realized in 124 of the 172 given treatment, the proportion of cures growing larger each year with his increasing confidence in treatment addressed to the causal hysteria (pithiatism). An important aid in this is to segregate the cases of aphonia, and to have cured cases among them. The unconscious suggestion from these cured cases is an invaluable factor in the cure. One of the men had recurring spasm of the glottis compelling intubation ten times in the course of seventeen days, but he was readily cured when he was witness of the cure of others. Garel declares that every case of symmetrical paretic aphonia will subside in time. Reeducation is the best method of treatment of aphonia in man or woman. He has the patient make a forcible expiration, like a sigh, repeating this and finally getting the patient to make this expiration audible with a sound in a low tone. This sound can be elicited by a sudden pressure on the epigastrium with one hand, the other hand on the back. With this simple maneuver, the expiration is accompanied by a sound, and the patient is urged to reenforce this sound voluntarily, to utter the vowels during a series of brusque expirations. In less than two minutes, by this means he cured aphonia in one case of nine years' standing. The laryngoscope will reveal paralysis of the vocal cords, and in eleven cases the mere introduction of the laryngoscope alone cured the aphonia. In others, backward pressure on the sides of the thyroid cartilage, the head lowered, as an effort is made to speak, answered the purpose. He never obtained any benefit from hypnosis.

*Malarial Meningitis. G. Paisseau and J. Hutinel.—p. 197.
*Vaccine as Adjuvant in Gonorrhea. Baril and P. Creuzé.—p. 202.
Pseudo-Mumps. Denéchau.—p. 208.
*The Therapeutic Value of the Oculocardiac Reflex. R. Voisin and Benhamou.—p. 210.

Malarial Meningitis.—Paisseau and Hutinel give examples of reactions on the part of the meninges in the course of malaria, merely cytologic or more pronounced, sometimes intermittent, up to actual acute meningitis. When energetic treatment is instituted the acute meningitis subsides but it may leave tardy sequelae, such as the ulceration of the cornea in a case described in detail. They comment on the analogy between malaria and syphilis as displayed anew by the meningeal reactions which each may present. They warn also that the peripheral blood may be free from parasites during these pernicious phases of malarial infection. The pernicious character is not necessarily due to particularly intense infection but merely to the localization of the parasites in some special organ. Considerable bibliography is appended.

Vaccine Therapy in Gonorrhea.—Baril and Creuzé obtained the cure in from twelve to twenty-five days in 95 per cent. of 300 cases of acute or chronic gonorrhea, including fifty cases in women. They ascribe this success and the shortening of the course of the disease to the combination of a polyvalent vaccine with local treatment of the urethritis or vaginitis, plus systematic dilatation of the urethra in the old cases. The vaccine was injected on alternate days, in the gluteal muscles, to a total of eight injections. The lavages are not begun until about the fourth injection of the vaccine, when the general defensive reaction is at a certain height. They prefer mercury oxycyanid to permanganate for the local treatment, using a 1:8,000 up to a 1:4,000 solution.

Therapeutic Application of the Oculocardiac Reflex.—Voisin and Benhamou were surprised to find in two cases of essential paroxysmal tachycardia, without heart disease, that under pressure on the eyeball the tachycardia subsided. These patients were a woman of 40 and a young man; in the latter the pressure had to be kept up for two or three minutes to ensure a permanent result. In other cases the tachycardia was constant, and pressure on the eyeball modified it for two or three hours, the subject feeling the marked modification of the heart beat and in this way being favorably impressed and stabilized. In neuroses, this is an important adjuvant, as also in certain manifestations of hysteria, epileptiform seizures, tremor, etc.

Hexamethylenamin by the Vein in Influenza. H. Michel.—p. 126.

Bronchopulmonary Spirochetosis.—Dalimier remarks that men with Castellani's spirochetosis present the clinical picture of pulmonary tuberculosis, but the lung findings and sputum are almost negative and there is no fever, although the men are constantly spitting blood. The spirochete in question is of all lengths and sizes, and with from one to ten twists. In two of his cases this spirochetosis had kept up for more than a year. The hemoptysis although frequent was never severe, and no complications were observed, but the debility in the chronic cases may invite other infections, especially tuberculosis. This spirochetosis is contagious but not violently so. None of the usual measures for hemoptysis did any good. The best results were obtained with a daily dose of 60 gm. of wine of cinchona with 10 drops of Fowler's solution. This seemed to have a distinct action on the expectoration of blood.

*Cystoscopy with Uterine Cancer. P. Cruet.—p. 3.
Case of Tardy Rotation of the Head. S. Rémy.—p. 24.
Pituitary in Obstetrics and Gynecology. L. Pouliot.—p. 27. Cont'n.

The "Revue."—This review suspended publication during the war, but now resumes its monthly issue, the fourteenth year since its foundation. Cruet's article opens the list, the last from his pen, as he was one of the victims of the war. The three leading articles are accompanied by summaries in English and in Spanish.

Cystoscopy in the Diagnosis of Cancer of Uterine Cervix.—Cruet analyzes what has been written on this subject in different countries, saying that there are now 500 cases in which the cystoscopic findings have been recorded with cancer of the cervix. His own experience with ten operable and seventeen inoperable cases confirms the general opinion that simple bulging of the floor of the bladder has no diagnostic significance. When the floor is thrown up into folds, with deep valleys between, we can count on there being tight inflammatory adhesions which will hamper the operation on the cancer, but do not contraindicate it absolutely. When there is edema of any kind, there are usually extremely close adhesions, possibly of a malignant nature, which render the operation dangerous and, he thinks, stamp the case as inoperable. The majority of writers report that they never had any difficulty in operating when the cystoscopic findings were negative, but invariably, when they were positive. However, there is no agreement between them as to what constitutes positive findings.

Cruet regards the aspect of the mouth of the ureter as suggestive when it is pushed up or to one side by the bulging of the bladder floor. The ureter mouths may be surrounded by abnormal vascularization, diffusely red, with edema, but the most characteristic findings are (1) the enlargement and flattening out of the orifice, suggesting stenosis just above, and (2) the edematous protrusion of the ureter mouth. This protrusion may give it a volcano-like aspect. When the ureter is compressed, the interval between the spurts of urine is longer and the jet stronger. In normal conditions the intervals are of equal length with both ureters. Compression is also liable to induce spasm of the mouth of the ureter, fractioning the ejaculation.

Cruet also noticed that when the ureter had been invaded there were no folds in the bladder mucosa around the ureter mouth after ejaculation. Catheterization of the ureter may also give useful information, and it may aid in the operation to leave the catheter in place. Four plates that should have accompanied this article, are to follow later.

Regeneration of Human Tissues.—In this eighteenth report on the results of his research on regeneration in man, Bier discusses the interstices of loose connective tissue, regarding them as analogous with the synovial spaces.

Psychogenous Deafness and Deafmutism.—Sommer sets the patient to examining the record of his tremor on a registering drum. When absorbed in this, a loud gong is struck just behind him. The register shows the effect of the shock, and it is easy then to convince him that he has "regained" his hearing.

Campaign Against Venereal Disease.—Blaschko asserts that the public must be educated to realize that venereal disease can be effectually aborted if treated at once after infection. All physicians must be trained to recognize venereal disease at once. When these two conditions are realized, then prompt application for treatment and the immediate recognition of the disease and giving of proper treatment will prove a great advance in the prophylaxis of venereal disease.

Typhus.—Dienes argues to explain why the serum of typhus patients agglutinates certain strains of the proteus.

Sounds from Heart and Vessels Heard at a Distance.—Hampeln discusses the sounds heard at a distance, saying that the first heart sound can be heard at remote points in both physiologic and pathologic conditions, as also the second heart sound. Sometimes a sound can be heard in a peripheral region, as for instance, a volar sound in the palm.

Occult Blood in Stools.—Baumstark has been carrying on a lively controversy with Boas and others in regard to occult blood in the stools, as his experience with 254 cases of stomach or bowel disease showed often positive findings in the complete absence of ulcer or cancer. He reiterates that occult blood in the stools should not be regarded as of decisive differential diagnostic importance in dubious cases.

Chirurgia degli Organi di Movimento, Bologna

February, 1919, **3**, No. 1

*Fracture of the Clavicle. A. Catterina.—p. 1.
*Purulent Arthritis of Tarsus. O. Uffreduzzi and G. Serafini.—p. 20.
*War Fracture of Femur or Humerus. U. Camera.—p. 29.
*Operative Treatment of Causalgia. G. D'Agata.—p. 55.
Bacterial Flora in Amputation Stumps. G. Vernoni.—p. 71.
*Amputation Stumps. A. Chiasserini.—p. 97.
*Partial Amputation of the Hand. F. Delitala.—p. 115.
*Attachment for Artificial Working Hands. V. Putti.—p. 122.

Fracture of the Clavicle.—Catterina reviews the various methods in vogue for treating war and peace fractures of the clavicle, and describes his experiences with seven different technics applied on the cadaver. He also describes the findings with radiologic control on the living, and the ultimate outcome. With a subcutaneous fracture of the clavicle, no apparatus will guarantee perfect coaptation of the fragments, and hence he advocates surgical treatment as the only means to reduce the fragments and ensure their perfect contention. If this is not deemed advisable, the arm should be immobilized in abduction or inward rotation.

Purulent Arthritis of the Tarsus.—Uffreduzzi and Serafini commend Obalinski's method for resection of the tarsus with rebellious suppurating wounds of the foot.

Orthopedic Treatment of Fractured Femur and Humerus.—Camera gives illustrations of some simple devices to facilitate orthopedic treatment of firearm wounds with fracture of the femur or humerus.

Operative Treatment of Causalgia.—In D'Agata's case there was paralysis of the nerves forming the brachial plexus, in addition to the causalgia—all the result of a war wound. The nerves were found embedded in a mass of cicatricial tissue which was excised, releasing the nerves. The pains subsided at once but soon returned, although there was progressive improvement in other symptoms. As the causalgia persisted unbearable, two months later he resected the nerve sheath enveloping the brachial artery, freeing it by this periarterial sympathectomy for a stretch of 12 cm. This cured the pains, and the motor disturbances have gradually retrogressed. Before the operations the condition had been growing slowly but steadily worse. The neurolysis affected favorably the neuritic pains, but the periarterial sympathectomy put an end to the vasomotor, trophic and secretory disturbances.

Secondary Treatment of War Stumps.—Chiasserini pleads for amputations by technics that will ensure better against conical stumps. The best way to manage these stumps after protracted suppuration seems to be with an osteoplastic reamputation after the local inflammatory process has subsided or become much attenuated. It may even be possible to loosen up the tissues around enough for a plastic operation without cutting the bone further, as he shows with a few illustrations of some cases.

Partial Amputation of the Hand.—Delitala discusses this subject from the standpoint of the prosthesis. In some of the devices illustrated the fingers of the prosthesis are immovably curved but the thumb is movable, or vice versa, and is controlled by the movements of the stump of the hand inside the prosthesis. This is possible even with amputation close to the carpus.

Attachments for Working Hands.—Putti's illustrations show the simple harness which fastens the working prosthesis to the stump and body, thus reenforcing the stump with the strength of the body. One illustration shows the whole body suspended from the working claw hand hooked over a branch. Another shows a tug-of-war between two men whose claw hands are hooked together.

Feb. 27, 1919, **40**, No. 17

War Mutism and Its Treatment. F. Brunetti and L. Giaculli.—p. 129.

Summer Raynaud's Disease.—In Castellino's 1895 compilation of 316 cases of Raynaud's disease, syphilis was incriminated as responsible for the affection in 22 cases; malaria in 19; alcoholism and arteriosclerosis in 16; diabetes in 23; tuberculosis in 14; pernicious anemia in 9; leukemia, nephritis and heart disease in from 8 to 12 each; typhoid, pneumonia and rheumatism in less than 5, and a neurosis in 171 cases. But in all of them the action of cold was the provocative factor. The cold need not be severe, even the change from a warm bed, getting up in a cool room, may be enough to bring on the disturbances. He reviews what has been written on the subject, and then describes a case that differs from all others in that the disturbances came on for the first time in August. The attacks of pain, numbness and cyanosis in feet and hands then returned regularly every morning and lasted from 8 till 10. The young man was of a frail constitution and had been sent to the hospital for disordered heart action but no organic defect could be found except that the spleen was enlarged. The attacks recurred every morning but subsided completely in November under vigorous quinin treatment. The blood was not examined for hematozoa but the response to quinin confirmed the assumption of a malarial origin as the young soldier had been serving in a malarial region.

*Calcium by the Vein in Spasmophilia. S. Maggiore.—p. 129.
*The Urochromogen Reaction in Children. U. Provinciali.—p. 139.
*Autograft in the Radius. N. Caprioli.—p. 151.
*Pituitary Insufficiency from Adenoids. P. Caliceti.—p. 161.

Calcium by the Vein in Spasmophilia.—Maggiore injected calcium intravenously in eight children with tetany, mostly with rachitis. The youngest was 20 months, the oldest 10 years old, and electric tests were applied just before and at one, two, three, four, twelve, forty-eight and seventy-two hours thereafter. The dose was 1, 2, 3 or 5 cg. of calcium chlorid with enough of the vehicle to make 5 c.c. Each child was treated twice. No inconveniences were observed from the intravenous administration, while the drug promptly reduced the galvanic excitability of the nerves. This effect was most pronounced by the third hour and began to decline by the twelfth. The responses to the electric tests became approximately normal, and this effect was equally apparent with the second application of the drug.

The Urochromogen Reaction in Children.—Provinciali was unable to obtain any characteristic findings with Weiss' urochromogen reaction in tuberculosis, typhoid or paratyphoid. A positive response is obtained in almost all prolonged febrile conditions.

Autograft for the Radius.—Caprioli remarks that autografts come under the head of physiology rather than of surgery, and that they deserve a wider application. In a case described, a healthy boy of 10 developed a psudarthrosis after a fracture of the forearm which had suppurated for two months. The bone had become demineralized and had shrunken in size. He gives an illustrated description of the implanting of a graft taken from the tibia, the whole done at one sitting. The success was complete. This case confirms the advantages of cutting the grafts without preventive hemostasis. When implanting it, however, the blood should be entirely expelled from the region. The graft was kept in sterile gauze while the bed was being prepared for it.

Pituitary Disturbance from Adenoids.—Caliceti refers to the way in which the pituitary may be damaged by adenoids. The resulting set of symptoms was described by Citelli, and Caliceti here reports two new cases and reaffirms the immense importance of prophylaxis, removing adenoids before they have time to injure the pituitary and entail, secondarily, disturbances in development both of body and mind. The body assumes a feminine aspect and there is more or less tendency to feeblemindedness. This can be arrested in some cases by pituitary treatment, but removal of the adenoids is indispensable also. Even adults with this "Citelli syndrome" are often rendered brighter, more alert and dependable by pituitary treatment, as in the case of a soldier here described.

*Prophylaxis of Influenza. V. E. Ovazza.—p. 271.
*Treatment of Influenza. S. Avagnina.—p. 272.
Opium Preparations in Cardiovascular Disease. G. Sabatini.—p. 275.

Influenza.—Ovazza records that although a number of persons contracted the influenza anew on its return in the fall, after having had it in the spring, yet the return cases were strikingly mild and always free from complications. This sustains the conception of a relative immunization, at least. He comments on the important change which seems to have been realized, almost simultaneously, in the hospitals thoroughout the world, namely, the refusal to admit visitors. The experiences in the pandemic seem also to have removed the lay dread of "going to the hospital" as practically equivalent to going to one's death. It is our task now to foster the idea that the hospital offers numerous advantages over the care in the home, and that the sick should discourage the visits of friends as liable to inflict complications on the sick while spreading disease outside. He denounces further the closing of schools unless the children are kept strictly in the house. Otherwise the children meet in the streets, and some children do not get any cleaning up except for school. There is no sense in closing the schools unless at the same time all public meeting places, street cars, etc., are abandoned likewise.

Treatment of Influenza.—Avagnina found bradycardia comparatively common in his over 2,000 cases of influenza, and it was constant in all those with bronchopneumonia. This confirms the assumption that influenza causes a vagotonic tendency, and it emphasizes further the inadvisability of giving digitalis in bronchopneumonia of influenzal origin.

*Leprosy at Rio de Janeiro. F. Terra.—p. 33. Concluded in No. 6, —p. 41.
Aerophagia. J. Cardoso.—p. 36.

Leprosy at Rio de Janeiro.—Terra quotes early authorities who commented on the fine, healthy appearance of the natives of Brazil when Europeans first appeared there. Nothing like leprosy seems to have been ever noted among them. It is scarcely likely that the negroes brought from Africa in such numbers imported the disease, as the slave dealers were careful to bring only selected specimens. Some years as many as 60,000 Africans were sold into slavery in Brazil, but in 1850 this practice was repressed by legislation. The Portuguese who colonized the country seem to have imported leprosy. It was first noted about 1600. In 1766 a total of 300 cases were known at Rio, with a population of 60,000. There has been no census of lepers taken at any time, but Terra concludes from his personal investigations and the hospital records that there are now about 450 or 500 cases—350 lepers are officially known. This for a population of 1 million shows that leprosy has not increased proportionately to the increase in the population. He urges the founding of a leper farm colony.

*Operative Treatment of Chronic Constipation. B. H. Zapata.—p. 1.
The Public Hospital System of Lima. C. A. Bambarén.—p. 21.

Operative Treatment of Chronic Constipation.—Zapata relates the details of eight cases to emphasize the importance of operative treatment in certain cases of chronic constipation in which nothing but removal of adhesions, binding the bowel at some point, could possibly have given relief. He warns that constipation of a merely medical character may induce the formation of adhesions around some point where there is retention of feces. Prevention of adhesions and kinks depends also on prophylaxis of inflammatory processes in the peritoneum. Each case requires individual treatment, and the eight described show the wide range of indications to correct kinks, membrane formation, ptosis, or other anomaly responsible for the intractable constipation.

*Emetin with Amebic Liver Abscess. E. P. de Bellard.—p. 25.
*Balantidium Dysentery. E. P. de Bellard.—p. 27.

Amebic Liver Abscess.—The abscess in the first of de Bellard's two cases had developed insidiously, ten months after a mild and brief attack of dysentery. The symptoms were almost exclusively from the lung forced up by the tumor in the liver. The case had been mistakenly labeled "advanced pulmonary tuberculosis plus malarial hepatitis." The large abscess in the other case had been ascribed merely to simple hepatitis. The right lobe of the liver was involved in both, and after aspiration of the contents of the abscess, emetin was injected into the cavity: 0.15 gm. of emetin in 30 c.c. of distilled water. Recovery was prompt and complete. The pus aspirated totaled 2,850 c.c. in one case and 1,900 c.c. in the other in which two abscesses were found. The operation had been preceded by subcutaneous injection of 0.04 gm. emetin, morning and evening, for three or four days.

Balantidium Dysentery.—De Bellard reports another case of balantidium dysentery, the twenty-eighth published in Venezuela and the fourth he has encountered himself. In the 154 cases on record the mortality was 23 per cent. In his four cases the domestic animals shared the family dwelling place. In his latest case the man of 50 had been ailing for two years with a debilitating diarrhea and severe abdominal pains, vertigo and headache, and discomfort in the colon region. The colon was flushed twice a day with 1 l. of a 1 per thousand solution of quinin sulphate, and 3 drops of an iodin-iodid solution (Lugol's solution) were taken internally three times a day. Improvement followed at once, and in a week the stools were free from the balantidium with which they had swarmed before.

Horse Serum as Hemostatic. H. Sanchez B. and C. J. Bello.—p. 213.
*Abscess in the Liver. C. J. Bello and H. Sanchez B.—p. 217.

Emetin by the Vein.—Bello tabulates a number of cases in which emetin has been administered intravenously by different clinicians in various countries in treatment of amebic dysentery. He also gives the details of eleven cases from his own practice. All this testimony shows apparent tolerance for the doses employed. The only deaths were in the cases in which the ameba was not responsible for the dysentery, and the disease continued its fatal course. One boy of 12 with dysentery for two months was given 0.21 gm. of emetin by the vein in five days, the first dose 0.07 gm. The cure was complete and permanent, and the drug caused absolutely no disturbances. The tolerance was complete in all his cases even when up to 0.28 gm. was given in five days. The cases with other intestinal parasites were the most refractory.

Pseudo-Ovaritis in the Hysteric.—Sanchez and Bello report two cases in which at the laparotomy—on the presumptive diagnosis of ovaritis or salpingitis—the adnexa were found intact in one and with an insignificant cyst in the other case. Both women were permanently cured, over one year to date, by the laparotomies.

Liver Abscesses.—Bello and Sanchez remark that tropical liver abscess has become a much less serious affection since emetin treatment has been introduced. It may cure alone, but in cases of long standing, it should be supplemented with operative treatment. The latter is much less serious when reenforced with emetin than it used to be, as they show by six clinical cases reported.

The "Plus Ultra."—This recently founded medical monthly is unique in several respects: its large size, 11 by 15 inches, its large plates in color photography, its numerous collective or synthetic reviews on different branches of medicine and surgery, and its high price, 70 pesetas a year, about $14. The paper and illustrations are of the best, and the name "Plus Ultra"—not "Non"—means "More Beyond." It aims for world-wide collaboration in the five principal languages. "Plus Ultra" is the proud motto of Spain. She dropped the "Non" when she added the Western Continent to the world.

Technic for Administration of Quinin in Malaria.—Casares treats malaria on what he says is a new principle, and states that 897 of his 1,072 malaria patients were cured by a single course of four doses; 129 required a second course and forty-six a third. The complete cure a year later was verified in [illegible] cases. The reason why more than one course was required in some cases was because the quinin was not given at the right time, or the patient had vomited the drug, or had neglected to take the whole of the four doses ordered. He noticed that when the chill comes on, the malarial subject feels extremely thirsty and drinks copiously or can be persuaded to drink large amounts of water without distaste. Examining the stomach shows that there is no protrusion, the water being evidently absorbed at once. Absorption in the stomach proceeds more rapidly when the water contains certain salts, especially chlorids. When the chill begins, the skin looks pale and there is more or less "goose flesh"; the blood is driven inward from the surface and there is hyperemia in the internal organs. As the chill subsides, the blood rushes to the surface of the body. While the internal arteries and veins are congested in this way, the return of the venous blood to the heart is impeded, and it is to regulate this that the thirst at this time is due. The quinin should reach the young parasites during their least resistant phase, that is, at the beginning of the chill. This can be accomplished by having the patient drink a large quantity of water containing less than 0.50 gm. of quinin. As the water is absorbed so rapidly, it diffuses through the whole vascular system and acts on the parasites in their remotest haunts as effectually as if the drug had been injected internally. He gives 0.20 gm. of quinin, with an arsenical preparation, on four successive days, always at the same hour, the first dose at the beginning of the chill. The paroxysm is more severe than previously, treated in this way, but no symptoms of toxic action from the drug are apparent.

Prensa Medica Argentina, Buenos Aires

Feb. 10, 1919, 5, No. 25

*Gummatous Pelvic Cellulitis. M. R. Castex.—p. 245.
Coxalgia in Boy of Ten from Inherited Syphilis. J. C. Vivaldo.—p. 246.
*Adaptation of Micro-Organisms and Phagocytosis. A. Bachmann.—p. 248.
Lesions of Nerve Fibers in Alcoholism. A. Jones.—p. 249.
*Cerebral Nystagmus. R. Argañaraz.—p. 250. Conc'n.
*Sugar Treatment of Pulmonary Tuberculosis. A. Raimondi.—p. 251.

Gummatous Pelvic Cellulitis.—Castex recently encountered two cases of gummatous pelvic cellulitis in the course of three months in men of 28 and 32. Intestinal disturbances had been noted for several months and a large tumor could be palpated, filling the pelvis but evidently not encroaching on the peritoneal cavity. There had been considerable loss of weight in both cases, and a sarcoma was suspected in the first. Signs of inherited syphilis were pronounced in one of the men; in the other it was impossible to tell whether the syphilis had been inherited or acquired. The remarkably good general condition suggested the possibility of gummatous cellulitis instead of malignant disease, and under intensive treatment for syphilis the whole clinical picture subsided completely in two or three months. The gummatous infiltration through the cavity of Luschka readily explained the symptoms from the rectum, bladder and prostate in both cases. The peritoneum was pushed up. In conclusion, Castex warns that the treatment had to be both intensive and prolonged to realize the complete cure. He knows of only one similar case on record, that reported by Fournier in 1912 in which the cellulitis had been the work of inherited syphilis in a man of 34.

Adaptation of Microbes to the Medium.—Bachmann's experimental research apparently establishes that when typhoid bacilli, for example, are injected into the peritoneum of a guinea-pig, they become transformed in a way that enables them to resist phagocytosis. This phase does not last long, but during it the bacilli seem to generate products which have the effect of repelling the leukocytes from the peritoneal cavity. The consequence is that, after this phase, although the bacilli no longer resist phagocytosis, yet there are not enough phagocytes present to make any impression on them.

Cerebral Nystagmus.—Argañaraz presents anatomic and experimental evidence which apparently demonstrates that conjugated deviation of the eyes, paralyses of association and nystagmus are symptoms from lesions all located in the same anatomic territory; this he describes and explains with charts. He analyzes the spasmodic type of nystagmus, from irritation of the cortex, and the paralytic type, and reviews the features of the nystagmus accompanying different affections involving the cerebrospinal axis.

Sugar Treatment of Pulmonary Tuberculosis.—Raimondi found that injections of saccharose by Lo Monaco's technic gradually reduced expectoration and the cough but did not modify the fever. He was impressed with the value of the vasoconstricting action in combating the tendency to hemoptysis. The leukocytes increased in number, particularly the neutrophil polynuclears, while the lymphocytes declined in numbers and the general health improved, but the pulmonary process did not seem to be influenced with the sugar treatment in the least, in his experience at the Hospital Tornu.

*Tubercle Bacilli and Iodin Vapors. S. Dessy.—p. 1.
*Emetin with Amebic Liver Abscess. R. A. Marotta.—p. 3.

Tubercle Bacilli Cultures Subjected to Iodin Vapors.—Dessy places a few scraps of iodin in a perforated tube extending into an Erlenmeyer jar containing culture medium in which tubercle bacilli are growing. The tube does not touch the fluid below, but the vapors from the iodin escape through the perforation above. The virulence of the tubercle bacilli was attenuated thereby, but similar experiences with anthrax bacilli and staphylococci show that the latter are more susceptible than tubercle bacilli.

Emetin with Amebic Liver Abscess.—Marotta insists that emetin should always be given a trial at least before operating for an amebic abscess in the liver. In his fifty cases, nearly all the patients recovered under the subcutaneous injection of emetin alone. At most, puncture and aspiration of the pus supplemented the emetin.

*Spermatic Fluid as Aid in Diagnosis of Syphilis. V. Widakovich and M. Sires.—p. 79.
Thread Drainage of Hydrocele. J. Nin Posadas.—p. 81.
Relation Between Sanitary Progress and the Pandemic of Influenza. E. R. Coni.—p. 87.
*Improved Test Tubes for Research on the Blood. C. A. Grau.—p. 89.
Artificial Cells. A. L. Herrera.—p. 99.

Diagnosis of Syphilis from Spermatic Fluid.—Widakovich and Sires were impressed by the large proportion of deformed spermatozoa found in the spermatic fluid of syphilitics in comparison with normal conditions. In their examination of normal spermatic fluid they found only about 4.54 per thousand spermatozoa with two heads, two tails or other malformations, but in the syphilitics the proportion averaged 26.12, and in one syphilitic of 20, whose infection dated from sixteen months and had been given energetic treatment, the Wassermann reaction veering to negative, 19 spermatozoa were found with two tails, 7 with two heads, 6 with three tails, 7 with two heads and two tails, one with a small head and four tails, one with two heads and three tails, and other pathologic forms to a total of 101 in each thousand specimens. Another young man of the same age and other conditions, free from venereal disease, had only 11 per thousand pathologic forms. The proportions did not vary much in examinations at different intervals. One man with positive Wassermann reaction whose wife had had two abortions, showed 57 per thousand pathologic spermatozoa but the proportion dropped to 32 per thousand after energetic arsphenamin treatment. They spread small drops of the fresh semen on a slide, exposing it to the fumes of 1 per cent. osmic acid until it looks slightly grayish, and drying in the air like a specimen of blood. They stain with a mixture of recently saturated and filtered anilin water (agua de anilina) with as many drops of a saturated alcoholic solution of gentian violet as are needed to give the metallic glitter to the scum on the surface of the fluid. The stain is left in contact for two to five seconds and is then rinsed off for thirty to sixty seconds with running water.

Improved Test Tubes for Research on the Blood.—The advantages are obvious of the tubes which Grau proposes for sending blood for examination and for other purposes. They are ordinary test tubes which are heated in the flame till the glass softens, a short distance from the bottom. Then with a nail the glass is forced inward, partly closing the lumen at this point from both sides. A similar constriction is then made at a point a little further along, the lumen thus presenting two narrower points. The tube just above the middle is drawn out to make the whole tube narrower for a certain stretch. An opening can be made below this by heating the glass at the desired point and blowing into the tube from the top, fusing the top afterward. The blood can be injected from the syringe into this opening, and it clots much more completely and more evenly in the tube with these two narrow beadlike constrictions than in an ordinary tube, and the coagulum does not get shaken around and broken up in transit. Or, when the clot has entirely retracted, the tube can be inverted and the serum collecting in the other end of the tube can be hermetically sealed as in an ampule by breaking the tube in the middle and fusing the end.

*Torsion of the Pedicle of the Spleen. J. W. Kopp.—p. 379.
*The Nails with Arsenical Polyneuritis. R. A. Mees.—p. 391.

Torsion of the Pedicle of the Spleen.—Kopp concludes from a personal case reported in detail and study of the literature, that splenectomy should be the routine treatment with torsion of a movable spleen. He even advocates splenectomy as a precautionary measure when the movable spleen is large and liable to make trouble later. Otherwise he insists that the movable spleen must be replaced and fastened. Some believe that the congested spleen, once replaced, will become reduced to normal size, but Hall observed nothing of the kind in his eight cases in the course of the following year. The mortality with splenectomy for torsion of the spleen, was 11.5 per cent. in the thirty-five cases compiled. The sudden onset with intense pain and symptoms from the peritoneum, the tumor developing in a few hours, its shape suggesting that of a large spleen, and the absence of the normal area of dulness over the spleen, aid in differentiating torsion of the spleen. There is no rigidity of the abdominal wall at first. He warns against reducing the torsion, with splenopexy, as the organ may have been too much damaged to recuperate. Splenopexy may be followed by recurrence; and reduction of the spleen, trusting to adhesions to fasten it in place, usually proves illusory.

The Nails with Arsenical Polyneuritis.—Mees has encountered three cases in which an attempt at suicide or murder, with arsenic, was followed by the development of a broad white band or frame in the finger nails. All the nails were affected, and as the white band reached the outer edge of the nails it grew less distinct. After discussing this phenomenon from various points of view, he expresses his conviction, and gives his reasons therefor, to the effect that the white band is an actual deposit of arsenic in the nails. The discovery of these broad white bands in the nails with arsenical polyneuritis will confirm the diagnosis. The band is still distinct long after the arsenic has disappeared from the urine.

*Ulnar Neuritis After Trauma of Elbow. A. V. Neel.—p. 97. Commenced in No. 3, p. 65.
Narcotic Action of Magnesium Salts. H. C. Gram.—p. 110. Cont'n.

Ulnar Neuritis After Injury of the Elbow.—The special feature of five of the ten cases reported by Neel is that about fifty years had elapsed between the trauma of the elbow and the neuritis. The trauma had occurred at the age of 2, 4, 5, 6, 16 and 17, and in a number of cases on record the trauma had occurred in childhood although the deforming arthritis did not develop until adult life. In five of his ten cases the elbow was in a valgus position. The elbow may develop serious disturbance after an apparently slight trauma. When the elbow is held partly flexed all the time, the full excurflexion of the elbow thus hindered, the ulnar nerve is kept constantly stretched. In his other five cases, the intervals had been from twenty-five to thirty-five years. The paresthesias and pain spreading through the forearm, especially on the ulnar side, and the inability to use the thumb as usual are generally the first symptoms. As a rule, the elbow shows such changes that the trouble is recognized at once, but the connection with such remote trauma is hard to establish. In one of his cases the atrophy of muscles from the pathologic condition of the ulnar nerve—a consequence of the deforming arthritis in the elbow—was ascribed to some process acting on the spinal cord, and a futile exploratory laminectomy had been done. This mistake was made also in some of the cases on record. After the numbness and other sensory disturbances in the ulnar domain first attract attention, the course is rapid, the paresthesias and pains growing more pronounced during the following six months to a year and the hand growing weaker. The changes in the elbow are of different kinds but all injure the ulnar nerve, the resulting lesions being an interstitial neuritis with hypertrophy of the nerve, or a more acute process. As the condition is usually of such long standing, there is not much hope of relief from operative measures. The nerve has generally adapted itself to the exostoses.

*Rupture of Intestine from Contusion. G. Söderlund.—p. 191. In German.

Rupture of the Intestine from Contusion.—Söderlund discusses separately the clinical picture and indications with intraperitoneal and retroperitoneal subcutaneous rupture of the bowel, describing 16 cases of the former given operative treatment at the surgical clinic at Uppsala or Gothenburg since 1910; also 37 cases of retroperitoneal rupture on record, including 8 in which no operation was attempted and one case from his own experience. The general symptoms, shock and the temperature and pulse are instructive when they confirm the local findings but otherwise are not decisive. In the dubious cases, the patient once in the hospital, hourly or still more frequent examination of the abdomen, watching for spontaneous pain or aggravation of already existing pain, and tenderness in the abdominal wall, with palpation of the rectum, watching for tenderness or bulging of the rectal wall, and percussion, seeking for dulness in the region of the contusion, will warn of incipient peritonitis. He wiped out the abdominal cavity but never rinsed, suturing at once without draining. Over 72 per cent. of the patients recovered, and the fatal cases were the severer cases from the first. With a retroperitoneal rupture, operative treatment is difficult to plan and to carry out, the posterior wall of the bowel being hard to reach and still harder to suture. In most cases the resulting phlegmon spreads in the right side to the right kidney and along the psoas down to the pelvis. In his case, however, the phlegmon was on the left side. Death may follow from the diffuse peritonitis set up by the phlegmon or from its exceptionally toxic action. The greatest danger, however, is that when the abdomen has been opened, the retroperitoneal rupture may escape discovery. This occurred in 11 of the cases cited from the literature. The most characteristic finding is a bulging of the posterior parietal peritoneum in the region of the duodenum. Suture of a retroperitoneal rupture is not so easy as with the intraperitoneal, and in some of the cases the suture gav[illegible] hand, 3 of the patients were saved by a suture alone, a. seems indicated in the cases with comparatively sma ture, that is, not longer than half the periphery of the or when the wall of the bowel has not been much cr or the trauma is comparatively recent, that is, with an val of less than twelve hours. One case in which suture was done after an interval of seventeen hou minated fatally while the patient recovered in anothe with interval of only nine hours. Gastro-enterosto spare the suture strain, was done in some cases b advantages of this do not seem great enough to com the operation with it in most cases. Exclusion of the might be considered in connection with it as maki result more certain. But the general condition of the must decide here. Kranz resected the duodenum and both stumps, finishing with anterior gastro-enterostom patient died the twenty-eighth hour thereafter. In 2 cases with simple suture done after an interval of sev and twenty-four hours, the suture burst; resection injured stretch might have saved these patients: both men lived a week. Catgut had been used, but the ne findings showed that it would have made no difference suture had been done with silk. Söderlund discusses the special technics for rupture at different points bowel.

Idiopathic Dilatation of the Esophagus.—Gregerse cusses the present status of our knowledge of idio dilatation of the esophagus, saying that in the major cases it is the result of spasm of the cardia. Occasio however, it is due to paralysis of the musculature esophagus, and he reports a case of this latter kind. cardia was of normal size, but the esophagus musculatu not work properly. He corrected the resulting conditi enlarging the opening of the cardia. This allowed the in the esophagus to drop into the stomach by its own w and there were no further disturbances. The cardia dilated in the simplest and easiest way by introduc catheter passed through a rubber bag, fastened airtig the catheter, commencing near the tip and extending for some distance. After the tip has been pushed th the cardia, the rubber bag is inflated with air or filled water, the pressure regulated by a manometer. Regula strong pressure can thus be exerted on the cardia, a rubber bag can be inflated to a circumference of 12 cm. rubber bag is made with two layers of rubber with o silk between.

The Wassermann Reaction at a General Hospital.—Me gracht states that a positive reaction was obtained in cent. of 504 of the patients in the medical service Rigshospital. In 1.2 per cent. the positive reaction w that called attention to the syphilis. Less than 50 per were aware of their infection or even suspected its poss Nearly 15 per cent. of the patients with cardiovascula ease were syphilitic, and 12 per cent. of the nephritics

Chronic Dry Rhinopharyngitis.—Kragh describes cases in which after an operation on the nose, or s neously, the throat became so dry and parched as constant annoyance. He reasoned that the dryness result of too rapid and ample passage of the air throu nasopharynx, not allowing it time to get the normal i nation with moisture. To remedy this, he advised the pa to wear a small pledget of cotton in each side of the not large enough to interfere with the breathing but ch to some extent the inflow of air, and catching some moisture in the outgoing air so that the entering air better chance to become slightly moist. The results passed his anticipations. The patients wear the pledgets when they feel the need of them. His communication is [illegible] Proceedings.

sions of the elbow thus hindered, the ulnar nerve is kept constantly stretched. In his other five cases, the intervals had been from twenty-five to thirty-five years. The paresthesias and pain spreading through the forearm, especially on the ulnar side, and the inability to use the thumb as usual are generally the first symptoms. drops of 15 per cent. sodium hydroxid after the solution has cleared, and, when in doubt, he resorts to the use of litmus paper. In spite of these measures reactions will occur, and since those cases seen responded to epinephrin, it is Beeson's belief that suprarenal insufficiency is the determining factor in their production. Hence epinephrin is administered. One milligram may be given intramuscularly ten minutes before the intravenous injection. In those presenting marked nitroid crisis, Beeson has not hesitated to give double that amount.

Use of Rubber Gloves in Surgical Operations. R. T. Morris, New York.—p. 52.

Compound Fractures of Skull.—In cases of this type Sachs advocates the excision of all traumatized tissue, scalp, dura, and brain tissue, replacing the defect in the dura by a transplanted piece of fascia and closing the skin completely without drainage. He has applied this method in two cases with most satisfactory results. The cases are cited.

Roentgenograms of Skull.—It is claimed by Moore that the radiolucent semilunar shadows seen so often in roentgenograms of the head are due to faulty apparatus, especially the cassette, and are of no clinical significance.

Cancer of the Superior Maxilla.—Early and thorough operation is advocated by Schley, thus often leading to a cure because cancer of the upper jaw, especially in the maxillary antrum, remains a local disease until comparatively late. With good preparation and technic the operative mortality is not large. Not a few even advanced cases are cured by a thorough operation.

Nonparasitic Cysts of Spleen.—The case cited by Lambert substantiates the fact that there is no group of symptoms which can be recognized as characteristic of splenic cysts. The cases present a varied picture referable to neighboring organs and directly due to the great enlargement. The spleen was removed successfully in this case, which is presented because it brings up the interesting question of the pathogenesis of cysts lined by connective-tissue cells occurring in various parts of the body, as in bones, thyroid gland, omentum, mesentery and elsewhere. Twelve years previously the patient was severely injured in an automobile accident. Lambert suggests that the cysts may have developed as the result of an infarct or a hematoma.

Chronic Intestinal Obstruction.—Pain was a constant symptom in the four cases cited by Behrend, not always, however, specific in character as to the location of the lesions. Vomiting, a constant symptom in acute intestinal obstruction, was present to a considerable degree in only one case. The other patients vomited rarely or not at all. The pulses of all the patients were not rapid. Another striking feature was the absence of toxemia in these cases, so commonly found in acute cases. All the patients reported recovered, and are still enjoying good health, whereas in acute intestinal obstruction the mortality is 50 to 60 per cent. In two cases the obstruction was caused by adhesions, in another by a slowly forming volvulus. The fourth case, one of purpura hemorrhagica intestinalis, illustrates one of the rarest conditions causing symptoms of chronic intestinal obstruction. A diagnosis of cholecystitis was made on account of the greatest tenderness being in the right hypochondriac region. Gallbladder disease was actually present on account of the black gummy bile which flowed with great difficulty through the cannula. On making a separate incision to remove the appendix an excess of intraperitoneal fluid was noted. This led to the discovery of the hemorrhagic masses extending from the jejunum and including the ileum.

Resection of Cecum and Ascending Colon. — Horsley describes the operative technic which he employed in seven cases of resection of the cecum and ascending colon. In all of them the principles of end-to-end union, ligation of the triangular space on the mesenteric border of the bowel before opening the bowel, and cleaning out the ends of the bowel before suturing were carried out, though in only one case was a valve formed. In one case, the Barber operation was performed, transplanting the ileocecal valve. All of the patients recovered from the operation satisfactorily. An enterostomy was not done in any of these cases.

Torsion of Appendices Epiploicae.—To the cases reported in literature Hunt adds eleven cases which have been under observation in the Mayo Clinic in the past ten years. Seven of these cases are true torsion of the appendix epiploica; one is of doubtful torsion, acting as a band producing intestinal obstruction; two are of incarceration in a left inguinal hernia, and one is of a foreign body in the peritoneal cavity with unproved origin from an appendix epiploica. Four of the cases of torsion presented acute symptoms, for which operation was done, and in the remaining three cases the torsion was probably symptomless, as it was found in the course of abdominal operations for other pathologic conditions. The cases in which there was incarceration in a hernial sac presented symptoms of incarceration of the hernial contents. The foreign body was found in the course of an operation for postoperative hernia, and the appendix epiploica, producing the obstruction of the sigmoid, manifested symptoms of chronic intestinal obstruction.

Legg's Disease.—Legg's disease is an error in development of the whole upper epiphysis of the femur—trochanter, neck and head. In this the acetabulum sometimes shares. It affects chiefly the head and the proximal lateral portion of the neck, and the cartilage between them. The great trochanter may or may not be involved. Five cases are reported by Ely.

*Anaphylaxis and Its Relations to Some Diatheses Common to Infancy and Childhood. F. W. Schlutz and W. P. Larson, Minneapolis. —p. 705.
*Mantoux Reaction in Children. O. Reiss, Los Angeles.—p. 714.
Minnesota Plan for Establishment of Infant Welfare Clinics in Smaller Towns. E. J. Huenekens, Minneapolis.—p. 718.

Anaphylaxis.—The experimental work done by Schlutz and Larson consists of the passive sensitization of guinea-pigs against foreign protein by injecting them with the blood serum of patients who seemed to be anaphylactic to these proteins. Their clinical observations were made on four types of cases: (1) extreme atrophy cases; (2) cases of overfeeding with cow's milk; (3) periodic vomiting cases, and (4) cases of the constitutional diathesis styled by Czerny the inflammatory exudative diathesis. The technic adopted was the following: from 3 to 5 c.c. of blood was drawn from the patient. This was allowed to clot and then centrifuged and about one half that quantity of serum obtained. Such serum was injected either intravenously or intraperitoneally into guinea-pigs of 250 to 300 gm. As a rule, the animals showed no signs or ill effects from the serum. Twenty-four hours later the animals were injected with a small quantity of milk, usually intraperitoneally, although sometimes the intravenous method was used. The quantity of milk injected varied from 0.1 to 1.0 c.c. Marked anaphylactic phenomena were obtained in the animals which had received the blood serum from inflammatory exudative diathesis cases. In several of the periodic vomiting cases, similar phenomena were observed. Some of the animals presented the typical picture of Smith's phenomenon. In some of the cases the reaction was followed by bloody stool. Death often occurred within twenty-four hours following the experiment, but more often from two to five days later. The experiments with marasmus, milk overfeeding, and periodic vomiting have not as yet been completed. The results so far obtained, however, would indicate that the reaction is not as clear cut as in the cases of inflammatory exudative diathesis. From the results of their work thus far it appears to Schlutz and Larson that in at least one type of cases studied (inflammatory exudative diathesis type) definite anaphylaxis to foreign protein exists, and that probably the majority of the phenomena occurring in this condition are truly anaphylactic.

Mantoux Reaction in Children.—For the purpose of checking up the von Pirquet test with some other of the cutaneous tuberculin test, Mantoux intracutaneous injection was done by Reiss on children. A solution of old tuberculin in normal salt solution, 2 min., or 0.005 mg., was used for the Mantoux; normal salt solution for the control. Nineteen of the 120 cases gave positive reactions; one doubtful reaction was classed as negative. The von Pirquet test was never positive in the absence of a positive Mantoux. It was negative in three cases which gave a positive Mantoux. Seventeen of the nineteen positives displayed adenopathy, and of these thirteen, only in two were the posterior cervicals enlarged. Reiss concludes that the intracutaneous tuberculin test when carefully performed seemed somewhat more reliable than the von Pirquet. Tuberculous meningitis cases apparently do not respond to cutaneous tuberculin tests (four cases after repeated tests uniformly gave negative results). The presence of posterior cervical adenopathy in children is highly suggestive of tuberculous infection.

Fluoroscopy of Cerebral Ventricles.—The lateral cerebral ventricles, when filled with air, can be clearly seen under the fluoroscope; twenty-five cases having been studied by Dandy by this method. The results in adults are equally as good as in children. By fluoroscopy hydrocephalus can be diagnosed accurately at all stages of its development. Several unsuspected cases of hydrocephalus have been demonstrated by the fluoroscope. The diagnosis of a false ventricular hernia (ventriculocele) was made with certainty, because the air from the ventricle could be seen to pass directly into the swelling. Fluoroscopy of the ventricle has practically the same range of utility as ventriculography, and almost the same results have been obtained. Following the injection of air into the ventricles, both fluoroscopy and ventriculography should be used.

Electromyographic Study of Chorea.—Five chorea patients were studied by Cobb. He found that choreiform movements give an electromyogram similar to that of a short, normal, voluntary muscular contraction. The inability to maintain voluntary contraction is clearly shown in the electromyograms. Weakness of muscular contraction is shown electromyographically by the lessened electrical discharge.

Pleurisy: Experimental and Clinical. R. C. Paterson, Saranac Lake, N. Y.—p. 160.

Clinical Study of Bronchial Asthma.—Of 400 cases of bronchial asthma studied by Walker, 191, or 48 per cent., gave a positive skin test and were, therefore, sensitive to some protein. Although the prevalence of asthma between the two sexes was about equally divided, the percentage of sensitive cases was a little higher among the males than among the females. The same number of patients had their first attack of asthma at each period of years with the exception that after the age of 45 there was a great decrease and after the age of 60 there were only three cases. The number of persons who developed asthma under the age of 2 and between the ages of 2 and 5 was as great as at any other age. The relationship between the age of onset of asthma and the sensitization of the individual is important. Four fifths of the patients who began to have asthma during infancy were sensitive, two thirds who began during childhood were sensitive; one half of those beginning asthma during young adult life were sensitive, one fourth of those beginning asthma during adult life were sensitive, and none were sensitive that began asthma after the age of 50; as the age of onset of asthma increases, the frequency of sensitization decreases. More patients were sensitive to the protein of *Staphylococcus pyogenes-aureus* than to any other type of bacterial protein, however, sensitization to the protein of *Staphylococcus pyogenes-albus* and the various streptococci was sufficiently frequent to warrant routine tests with these. In the above table the number of positive reactions with bacterial proteins is too conservative since many definitely positive reactions which do not measure 0.5 in diameter are obtained. It is of interest to note the effect of occupation on sensitization after the age of 40. Of the eleven patients who became sensitive to proteins after the age of 40, four were bakers and were sensitive to wheat protein, one was a hostler and was sensitive to horse dandruff protein, and another who was a sifter of green coffee beans was sensitive to green coffee protein. Seventy-eight patients were sensitive to the protein derived from animal hair. Sixty-eight patients were sensitive to food proteins. Ninety-two patients were sensitive to pollens.

Determination of Uric Acid in Urine.—A volumetric method for the determination of small amounts of uric acid in urine is described by Morris. It is based on the instantaneous and complete precipitation of uric acid as the zinc salt and a single direct titration with permanganate in a solution alkaline with sodium bicarbonate. The end-point used is the blue starch iodid color and, because of the mild nature of the oxidation and the excess iodid present, there is no fading to confuse the end-point.

Blood and Spinal Fluid.—Comparative analyses of blood and spinal fluid in fifteen cases are reported by Myers and Fine. The concentration of urea in the spinal fluid averaged 88 per cent. of that of the blood, the concentration of creatinin, 46 per cent.; that of uric acid, 5 per cent., and that of sugar, 57 per cent. These percentage differences represent the order of their solubility in water, and apparently also the order of their diffusibility.

Antiscorbutic Property of Vegetables.—The experiments carried out by Givens and McClugage show that the raw fresh tomato is a very efficient antiscorbutic agent. A small daily addition of this substance to a diet known to produce scurvy in guinea-pigs maintained these animals in apparently perfect health. Raw fresh tomatoes dried in a blast of air at either a low temperature (35 to 40 C.) or a high temperature (55 to 60 C.) retain a significant amount of their antiscorbutic potency. A daily supplement of 1 gm. of raw dried tomatoes protected guinea-pigs from experimental scurvy. Therefore, the tomato may be considered to contain some of the essential dietary substances.

Dietary Properties of Pea.—The data recorded by the authors contribute evidence in support of the general theory which they have formulated; viz., that vegetable foods having similar functions have likewise similar dietary properties. They also present records of experiments which show the supplementary relationships between the proteins of the pea and casein, gelatin, zein and lactalbumin, respectively. It is of great interest that while both casein and zein supplement the deficiencies of the pea proteins, gelatin and lactalbumin do not. From the failure of lactalbumin to supplement the proteins of the pea, or to induce growth when fed in the amounts used in the experiments described in this paper, the authors have come to the tentative conclusion that lactalbumin is either an incomplete protein or a poorly constituted one. They have been unable to obtain any growth in young rats with diets containing 18 per cent. of lactalbumin, as the sole source of protein, when the remainder of the food mixture was so constituted that good growth could be secured when the protein (18 per cent.) of the diet was casein.

Nitrogen Metabolism of Dog.—Experiments were undertaken by Rohde and Stockholm to determine how serviceable are small doses of commercial desiccated thyroid gland administered by mouth, as a means of increasing nitrogen elimination in the dog. The summary of results showing the average nitrogen figures for three days preceding thyroid feeding and for the days of administration, including two subsequent days, would indicate that a daily dose of 0.05 to 0.1 gm. of desiccated thyroid mixture per kilogram of body weight is a dose producing marked effect on nitrogen elimination and a somewhat greater percentage loss in weight than is found in the control animals. Nitrogen elimination in the dog receiving only sugar solutions may be increased approximately 50 per cent. by the administration, during a five to seven day period, of commercial disiccated thyroid gland in doses of 0.10 to 0.15 gm. per kilogram of body weight.

*Virulence or Adaptation? W. H. Woglom, New York.—p. 1.
Mammary Carcinoma in Cat. S. Itami, New York.—p. 19.
*Power of Mesodermal Derivatives to Immunize Mice Against Transplantable Tumors. S. Itami, New York.—p. 23.

Virulence or Adaptation?—Woglom suggests that it is possible that the factor which usually decides whether or not a spontaneous tumor can be transplanted successfully is adaptation. But it is equally probable that multiple spontaneous neoplasms occasionally vary in their proliferative energy; in most of them this is so low after transplantation as to be masked by a failure on the part of the tumor cells to adapt themselves, though in the case of a few growths it rises so high as to transcend the adaptive power of these elements.

Mesodermal Derivatives to Immunize Mice.—Experiments were undertaken by Itami to determine whether any other tissues share with the lens, brain, cartilage and bone, their inability to elicit a vigorous immunity. Two mesodermal derivatives—muscle and lymph node—were chosen. In order that the findings might not be vitiated by the presence of blood in these tissues, the greatest care was taken not to injure large vessels during the removal of the material; the small amount of blood contained in the muscle and the lymph node themselves may be regarded as insufficient to produce any immunity. Muscles or lymph nodes were removed from healthy mice, emulsified, and administered subcutaneously in the left axilla of normal young adult mice in doses of 0.5 c.c. (lymph node) and 0.1 c.c. (muscle). Into the opposite axillae of the animals thus injected, and into untreated normal controls of the same size and breed which had been kept aside under identical conditions, grafts (0.003 gm.) of tumor were implanted one to four weeks after the preliminary treatment. It became evident that preliminary treatment with normal tissues containing but few cells, whether they be of ectodermal or mesodermal origin, fails to induce immunity to transplantable carcinomas. Muscle, also, though this is more cellular, is inactive, for some reason at present unknown. Lymph node, on the contrary, has the power to elicit a high resistance against transplantable carcinomas. The mesodermal tissues investigated have no power to immunize against two connective tissue tumors employed, failing like the skin, to protect against sarcoma.

Indicator Method of Measuring Consumption of Oxygen.—For estimating the amount of oxygen consumed in respiration, Osterhout has investigated a number of substances, among them *Limulus* blood. The blood of the horseshoe crab (*Limulus*) absorbs oxygen and turns blue when shaken in air. In the presence of certain organisms which consume oxygen it is quickly decolorized. By measuring the time required for the change of color the rate of consumption of oxygen may be determined.

Effects of Anesthetics on Respiration.—A series of investigations on respiration with improved quantitative methods is being made by Osterhout. They show that when anesthetics are employed in sufficient concentration to produce any result, plants show a rise in the rate of respiration which is followed by a fall. In the animals studied, the rise (found in higher concentrations only) was preceded by a temporary fall which is not entirely due to lowering of muscular activity or tonus. In lower concentrations the effect on animals was merely a decrease of respiration. The results of all the investigations are opposed to the theory of Verworn.

Effects of Ether and Acetone on Respiration.—The action of anesthetics and some other substances on the respiration of a fungus (*Aspergillus niger*) was studied by Gustafson. In concentrations which are high enough to produce any effect, formaldehyd, ether, and acetone cause an increase, followed by a decrease, in the rate of respiration. Three and sixty-five hundredths per cent. ether, which causes an increase with certain cultures, produces only a decrease in others. The reaction producing an increase in the respiration with 7.3 per cent. ether is a reversible process, while the reaction producing the decrease is not reversible. Five-tenths per cent. caffein produces only a decrease in respiration while a saturated solution causes an increase, which is followed by a decrease.

Effect of Ether on Respiration of Bacteria.—A series of studies on the respiration of bacteria has been undertaken by Brooks. The organism selected for experimentation was *Bacillus subtilis*. Several other organisms were tried, namely, *B. mycoides, Staphylococcus pyogenes-albus, S. citreus, B. typhosus;* but *B. subtilis* was preferred because it was easy to handle. In all the concentrations of ether studied (from 0.037 to 7.3 per cent.) there is an increase in the rate of respiration of *B. subtilis* followed by a decrease. In 7.3 per cent. ether in tap water there is an extraordinary increase in the output of CO_2 (amounting to fifty times the normal). This does not occur when 0.85 per cent. NaCl is added, which indicates antagonism between ether and NaCl. Ether is toxic in low concentrations (0.037 to 1.1 per cent.) and high concentrations (3.65 to 7.3 per cent.) but in intermediate concentrations (1.1 to 3.65 per cent.) stimulates growth.

Effect of Ether on Respiration of Wheat.—Thomas studied the effect of ether on the respiration of wheat. His results are recorded.

Effect of Ether on Carbon Dioxid Output.—The purpose of Irwin's investigation was to make a comparison of the CO_2 output of animals with that of plants under the influence of a typical anesthetic such as ether. The experiments on frog tadpoles, an aquatic insect, *Dineutes assimilis* Aube, frog eggs, and *Fundulus* embryos were used. These experiments show that narcosis is not due to asphyxia. The action of anesthetics is due to some other cause than the effect on respiration. There is a difference between the animals studied and the plants described in this series, since in animals the increase in the CO_2 output is accompanied by irreversible changes leading to death, while this is not necessarily the case in plants. The reversible (narcotic) action of ether on the animals studied was accompanied by a decrease in the carbon dioxid output; in plants this is not ordinarily the case.

Control of Rope in Bread.—Rope is a condition of bacterial decomposition of bread which leads to a peculiar slimy or ropy consistency of portions of the interior of the loaf, produces an odor resembling that of ensilage, and renders the loaf unacceptable. Several closely related organisms have been isolated from ropy bread, some or all of which are undoubtedly the effective agents of the decomposition. The present investigation made by Cohn and his associates has been on a strain of *B. mesentericus* isolated from a ropy loaf. These investigations clearly show that the growth *B. mesentericus* is a function of the hydrogen ion concentration of the medium and that it is favored by the diminished hydrogen ion concentration which is due to the products of its own metabolism. This change in the hydrogen ion concentration may serve as a measure of the growth of the organism and as a means of identification. When possible, the hydrogen ion concentration of bread should be maintained near 10^{-5}N. Such practice would prevent the occurrence of rope. The reaction of dough and bread may be controlled with the help of a suitable indicator, and perhaps more conveniently by the use of a buffer mixture consisting of lactic acid and a lactate or acetic acid and an acetate. At present the simpliest method of controlling the reaction of dough or bread consists in the use of methyl red. When this indicator is colored red rather then orange, the reaction is sufficiently acid to prevent the development of rope.

Cancer of Tongue.—Tobacco, alcohol and syphilis, Power shows, are closely associated in the causation of cancer of the tongue. At the present time syphilis is more prevalent than it has been for many years, and the consumption of tobacco has risen from 7½ million pounds in 1914 to 8½ million pounds in 1915. Much of this tobacco is smoked in the form of cigarets, and women now smoke on a much larger scale than they used to do. It follows, therefore, that if matters are allowed to continue as they are doing, there will be a huge increase in the number of patients suffering from cancer of the tongue. The increase should begin about 1950, and it should affect women as well as men. Power claims that such an increase can be presented by a thorough and systematic treatment of syphilis in its initial stages; for, cancer of the tongue has always increased in frequency some years after syphilis has been treated inadequately. Persons who are being treated for syphilis, therefore, should be told never to smoke, not to drink to excess, and to make regular visits to a dentist in order that their teeth may be kept in the best possible state, and that any dentures they may have to wear should be maintained well fitting and free from rough edges. Such advice should be given while the patient is actually under treatment for syphilis. It is useless to defer it until the tongue has become sore, because it is then too late in a large number of instances.

Operative Treatment of Ruptured Internal Lateral Ligament of Knee.—The operation done by McMurray in ten cases results in changing the insertion of the sartorius muscle tendon from the inner aspect of the upper end of the tibia to the inner aspect of the lower end of the femur. A slightly curved incision, convex posteriorly, is made from 3 or 4 inches above the adductor tubercle to 1 inch below the tibial insertion of the internal lateral ligament. The anterior flap is reflected forward, and this discloses all the structures on the inner aspect of the joint. Lying slightly posterior to the joint, and held back by the fascia which covers it, is the sartorius tendon, lying close to the semitendinosus and gracilis. The fascia which secures the sartorius in its normal posterior position should be divided along the whole extent of the operative incision, so that the tendon can now be freely advanced. The femoral insertion of the internal lateral ligament is now clearly defined, a vertical slit about 1½ inches long is made through it down to the bone, and through this slit a small vertical wedge of bone is removed from the femur, large enough to admit of the sartorius being placed into it. This removal of bone is accomplished without interfering to any extent with the attachment of the ligament to the femur, so that no further weakening of the ligament is caused by it.

The sartorius tendon is pulled forward and laid in the groove in the femur in such a manner that the portion of the tendon between the femur and the tibia is quite tight, and it is then sutured firmly into the groove by stitches passing through the periosteum and the ligamentous insertion. When this has been accomplished successfully, the outer aspect of the internal lateral ligament is first scarified and then the ligament is tightened up in the usual manner by suturing adjacent portions of the scarified surfaces together. The fascia is now sutured along the line of incision, and skin sutures complete the closure of the operation wound. The knee should then be retained in the semiflexed position by means of splints or plaster for the next three months, when it will be found that full extension of the leg will be secured in the course of two or three weeks.

The success of the operation depends on keeping the knee in the flexed position during the whole course of the procedure, and the subsequent retention of this position during the minimum period of three months, in order to prevent stretching at the new insertion which will undoubtedly occur if strain is allowed to fall on it before this interval has elapsed.

Procedure for Avoiding Colostomy and Colectomy.—Short performs an end-to-side ileosigmoidostomy with division of the ileum, the distal end being brought out into the wound. By passing a catheter through it into the cecum, the gas can be drawn off; and flushing with warm water, containing an ounce or two of magnesium sulphate mixture, can be given through the catheter, which effectually clears the bowel.

Peripheral Nerve Injuries from a Surgical Aspect.—This paper is devoted to the study of the surgical treatment of war-injured nerves. Joyce dwells mainly on the operative treatment. He cites many cases, chosen from about 200 cases treated by nerve transplants and double lateral implantations, suture, neurolyses: (*a*) complete physiologic divisions; (*b*) incomplete physiologic divisions; (*c*) painful lesions; (*d*) cases associated with aneurysms and brachial plexus injuries, and alternative operations. Joyce found that in the majority of cases, delayed end-to-end union of a divided nerve is successful, and this method of repair is that of choice. Exploration of a physiologic completely divided nerve should be done as soon as the condition of the wound permits. Neurolysis combined with a capsulectomy of spindle-shaped neuromas has been followed by recovery in most, and improvement in all, cases in which this has been done; exsection of a spindle-shaped neuroma is not justified unless failure has resulted from a neurolysis capsulectomy. Nerve transplantations, and double lateral implantations of the ulnar into the median in the forearm, have been followed with some measure of success, including some recovery of voluntary power in the affected muscles; but recovery is slow and uncertain. Nerve growth takes place from both ends of a divided nerve, and from both ends of a nerve transplant, but axis cylinders grow down only from the central end. An autogenous nerve transplant, of smaller size than the nerve into which it is planted, is capable of hypertrophy. Axis cylinders, judged by Tinel's sign, grow at the average rate of 2 mm. per diem. Perineural scar tissue constricting young axis cylinders is the most important factor in hindering recovery.

Unusual Type of Fracture Dislocation of Upper End of Humerus.—Davies' case was one of subcoracoid dislocation of the head of the humerus, together with a spiral fracture passing downward and inward from the outer part of the head, ending on the inner aspect of the shaft of the bone just above its center.

Some Points About Bone Grafts.—Wheeler's opinions as to the inherent value of the bone graft are, in general, in accord with the views held by others. He believes that the periosteum should be left on the graft, because, although not essential, it is the medium through which new blood vessels enter the graft and the surrounding structures. Furthermore, in removing the periosteum superficial layers of osteoblasts may be sacrificed. A periosteum covered graft is less likely to become absorbed rapidly. As to what type of graft is to be used in certain cases, Wheeler says that in the case of the humerus and femur, long stout inlay grafts give the best results. Sliding grafts should only be employed in simple and fresh cases. But for slightly slower osteogenetic powers, and a real tendency to fracture, the intramedullary peg is effective. This method of bone grafting is satisfactory in the case of the radius and ulna.

Total Enucleation of Prostate.—In the 1,550 cases of total enucleation of the prostate performed by Freyer up to date, the mortality has been 5⅓ per cent., diminishing from 10 per cent. in the first 100 to 3 per cent. in the last 200 cases. Freyer advises early operation, before the vital organs, and particularly the kidneys, become secondarily affected.

Ureters and Their Orifices in Gunshot Wounds of Spine.—Cases with injury at the tenth, eleventh, and twelfth thoracic spinal segments were investigated by Fullerton to ascertain whether any relaxation or paralysis of the ureters or their sphincters is present in complete transverse lesions of the cord in the cervical and dorsal regions, in view of the frequency of "ascending" infection of the kidney. From this study Fullerton concludes that peristalsis of the ureters continues, as evidenced by the rhythmical discharge of urine rendered more visible by indigocarmin. Normal movements of the lips of the ureteral orifice take place, as evidenced by the visible systole and diastole present in all the cases. The tone of the ureterovesical sphincter is maintained and the valve is competent.

In order to avoid the disasters likely to result from the use of the catheter, other methods of treatment (pending the establishment of spontaneous micturition) have been suggested by various surgeons. One is to allow the bladder to distend until overflow takes place through the urethra (paradoxical incontinence). The urine is received into a receptacle placed between the patient's thighs. A second is to endeavor by pressure in the suprapubic region, combined, perhaps, with counterpressure by two fingers in the rectum, to overcome the resistance at the vesical outlet, and so to empty the bladder, partially at least. The important point to consider here is whether such distension or pressure is likely to force urine through the ureterovesical orifices toward the pelvis of the kidney. With this end in view, observations were made by Fullerton which showed that it appears to be safe, from the point of view of forcing the ureterovesical orifices, to attempt to empty the bladder by manual massage or pressure. Regurgitation into the pelvis of the kidney is not favored by any abnormal relaxation of the ureterovesical orifice special to spinal injuries. In fact, increased intravesical pressure, whether produced by urine or by fluid introduced through the urethra, actually tends to increase the efficiency of the valve formed by the oblique course of the lower end of the ureter through the coats of the bladder, provided that the ureteral orifice is not paralyzed or dilated.

Filter Passing Virus in Certain Diseases.—The virus isolated by the authors in trench fever consists of minute coccus-like bodies, grouped in pairs, with the opposing surfaces flattened, and varying in size from 0.3 to 0.5 microns. It is gram-positive and stains readily if the film preparations are washed in ether before the stain is applied. It passes through Berkefeld N and V filters, and also through Massen porcelain filters, and can be cultivated from such filtrates. It resists heating to a temperature of 56 C. for thirty minutes, and it is an anaerobe. This organism has been recovered by culture from the blood in eleven out of fifteen cases of trench fever examined during the pyretic stage, and in three out of eight cases examined when apyretic. It was not found in over forty control cases where blood culture with the same technic was carried out. A similar organism was recovered from four separate supplies of infected louse excreta. It was not found in thirty-one specimens of excreta from batches of clean lice. The culture obtained either from the blood of man, or from louse excreta, when inoculated by scarification into man, produces a mild illness, and the organism can be recovered from the blood by culture during such illness, and also from clean lice fed on the patient during the illness.

The virus isolated in cases of influenza consists of very minute rounded coccus-like bodies, varying from 0.15 to 0.5 microns. It is gram-positive, and passes through Berkefeld N and V filters and Massen porcelain filters. It is an anaerobe, and resists heating to 56 C. for thirty minutes. It has been isolated by culture from the blood in six out of nine cases examined, from the sputum in six out of six examined, from pleural fluid in four out of four examined, and from the cerebrospinal fluid in the only case so examined. It has also been isolated from the lymph glands post mortem in the only two cases examined. This organism can not only be grown from the blood, and from exudates, but it can also be seen in stained films prepared from exudates—for example, sputum, pleural fluid, cerebrospinal fluid. The culture (second generation), when inoculated into animals subdurally or intravenously, produces illness in guinea-pigs and monkeys. Passage experiments done from such animals when slightly ill, by injecting their blood, bile, etc., into healthy animals, causes in these more severe and even fatal illness, and postmortem the same lesions are found. The organism has been recovered by culture from the tissues of such experimental animals.

The virus isolated in cases of nephritis characterized by the presence of pyrexia and hematuria at the onset consists of a round coccus-like body varying from 0.3 to 0.6 microns in size, and in culture, often occurring in the form of short chains of four individuals. The same organism may be seen in urinary sediments either singly or in pairs. It is gram-positive, and passes through Berkefeld N and V filters, and also through the Massen porcelain filter. It is an anaerobe, and resists heating to 56 C. for thirty minutes. It has been isolated from the blood in six out of nine cases examined, and from the urine in seven cases. The culture (second generation) when inoculated into animals, produces nephritis in monkeys and guinea-pigs. In severe cases pulmonary lesions are also present. An organism allied apparently to that of polyneuritis has been isolated from brain tissue in cases of encephalitis lethargica.

Inverted "T" in First Lead of Cardiogram.—An electrocardiogram taken from those patients who complained of dyspnea on exertion, fainting fits, edema, without showing any obvious causes accounting for the symptoms, showed the T in Lead I inverted in all these cases. All those patients who showed an inversion of T in the first lead have invariably shown one or more symptoms usually associated with defective heart action. The conclusion reached by Harris is that an inverted T in the first lead is a reliable sign of a damaged heart muscle.

Ectopic Gestation.—The case cited by Rose and Shaw is an example of a very early rupture—six weeks' pregnancy only—of the rarest of all types of ectopic pregnancy—viz., that in the interstitial part of the tube.

Two Stage Bone Grafting Operation.—Such a procedure is urged by Platt. The first operation is at once an attempt at wound sterilization, a provocative measure, and a reconstruction of the bed for the future graft. The bone transplantation is performed in from six to eight weeks after the uncomplicated healing of the first stage operation.

*Influenza and Vaccines. W. D. Emery.—p. 64.
*Treatment of Influenzal Bronchopneumonia: Vaccine Therapy. W. H. Wynn.—p. 77.
Nervous System in Influenza. W. Harris.—p. 59.

Influenza and Vaccines.—Emery reviews the bacteriology of influenza and the use of vaccines. He believes that the position of affairs at the present day is most unsatisfactory. Really but little more is known now than at the time of previous epidemics, when the disease was attributed to an "influence" from the heavenly bodies and named accordingly.

Influenzal Bronchopneumonia: Vaccine Therapy.—Wynn's experience leads him to believe that prompt treatment with vaccines (pneumococci, streptococci, influenza bacilli), within a few hours of the onset will definitely abort an attack of influenza. In the cases in which bronchopneumonia is present from the first, vaccine seems often to have the same good effect when it is injected early. The striking feature with the use of vaccines, as noted by Wynn, has been the almost constant fall in temperature following the injection. He says that the earlier the injection is made, the more likely is the fall to be final. In cases injected after the second day, more than one injection is usually required before the temperature finally settles. Occasionally, the first dose fails to cause a drop in the temperature, and a second larger dose is required to bring this about. If the fall of temperature occurred alone, or was followed by collapse or other bad signs, it would not be desirable, but the fall is associated with improvement in the aspect and in the pulse and respiration rate, which, in Wynn's opinion, indicate that it is due to a definite immunizing influence. The important points for successful treatment are to give an adequate dose as early as possible after the onset of symptoms. Inadequate dosage and delay will cause disappointment.

*The Bile-Pancreatic Juice Reflux with Duodenal Ulcer. C. B. Udaondo —p. 38.
Gastric Hypersecretion with Normal Functioning. Maingot and J. C. Roux.—p. 43.

Diagnosis of Syphilitic Tumors in Stomach and Intestine.—Bard does not agree with Fournier and others who deny that it is possible to differentiate a syphilitic tumor from other tumors in stomach and bowel. It has been his experience that in certain cases of smooth, regularly shaped tumors, extremely movable, not tender, growing very slowly and inducing local stenosis but without notable impairment of the general health, a history of syphilis can be generally elicited, and the tumor retrogresses under specific treatment unless it is of tuberculous origin. In the latter event, the delay for trial of specific treatment does no harm.

Technic for Examination in Disease of Digestive Tract.—Labbé outlines the system he follows in examining a patient who complains of stomach or bowel disturbance.

The Reflux of Bile with Duodenal Ulcer.—Udaondo has been studying the connection between the localization of the ulceration and the reflux into the stomach of the duodenal juices, the bile and pancreatic juice. The green discoloration or the tryptic ferment in the contents of the fasting stomach was found in 84.5 per cent of his 13 cases of ulcer in the first part of the duodenum; only in 22 per cent. with ulcer in the second part. In 32 cases of ulcer in the stomach remote from the pylorus, there was no duodenal reflux in 87.5 per cent., as also in 88.8 per cent. of 27 cases of ulcer on or near the pylorus. With induced reflux (Volhard's procedure) trypsin tests were positive in 81.8 and 87.5 per cent. of the cases of ulcer in the first and second parts of the duodenum, but only in 8.3 per cent. of the juxtapyloric ulcer cases. Lesions remote from the pylorus gave 33.3 per cent. positive responses.

*Daily Hygiene of the Mouth. P. Robin.—p. 49.
Microbiology of Influenza. Meunier.—p. 51.
*Healed Fracture of Jaw in Prehistoric Skull. M. Baudouin.—p. 52.

Postinfluenzal Gangrene.—Molina relates that a robust young woman, at the fifth month of pregnancy, was convalescing from a moderately severe influenza of the pulmonary form, when gangrene developed in the right leg, with delirium. The pain on palpation did not extend above the popliteal space and the leg was amputated at the middle third. The woman left the hospital, cured, in a week, the pregnancy apparently undisturbed. The femoral artery was found thrombosed at the point of amputation, showing that the pain on palpation and the thrombosis do not always coincide.

Polyvalent Vaccine Therapy.—Bezançon and Legroux report experiences which amply demonstrate the harmlessness of the polyvalent vaccine they have been using. It contains in 1 c.c. 4 millions pneumococci to 2 millions each of streptococci, Pfeiffer's bacillus and *Micrococcus aureus.* It seems best to inject the vaccine daily, about 0.25 c.c. at a time at first, increasing the dose to 1 c.c. In this way they injected up to a total of 13 c.c. In one group of sixty repatriated prisoners with influenza given this treatment, the mortality was 8 per cent, while it was 17.8 per cent. among the group of twenty-five not given this treatment.

Hygiene of the Mouth.—Robin emphasizes that in disease and in times of epidemics the virulence of the microbes in the mouth is presumably enhanced, and hence the toilet of the mouth becomes exceptionally important. The benefit from the cleansing of the teeth and gums and the daily hygiene of the mouth three times a day is mechanical. Dentifrices, etc., destroy the living cells more readily than they destroy microbes, predisposing the tissues to infections of all kinds, and they had better be abandoned. During epidemics, frequent gargling and rinsing out the mouth with very hot Ringer's solution is advisable for both the sick and well.

Pain in Thyroid from Contact as Sign of Incipient Exophthalmic Goiter.—Summarized page 527, Feb. 15, 1919.

Suture of Spinal Cord.—Claude says that the young man survived for eight months after the meningo myelorrhaphy. Necropsy confirmed that the cord had been completely severed at the tenth dorsal segment. The case reaffirms the folly of attempting myelorrhaphy, either early or late. Far from beneficial, it always entails complications of different kinds.

Tardy Chancres.—Bory reports a case in which prompt treatment arrested the primary chancre. Three years later it began again where it had left off, and then ran its typical course with roseola. In another case the secondary phenomena were retarded for eight months.

Brachial Paralysis from Cervical Rheumatism.—Léri's patients in this group presented amyotrophic paralysis of the left superior brachial plexus, and radiography revealed lesions of chronic rheumatism in the form of osteophytic protuberances and hooks in the left fourth or fifth cervical vertebrae, just at the emerging point of the fifth cervical root. In others the sixth or seventh vertebra showed the parrot beak projection causing the trouble. In some cases a supernumerary cervical rib was involved. He has encountered eight cases of this kind within a short time. There was nothing to call attention to the neck, the discovery of the bone lesions was casual but they were unquestionably the cause of the periscapular amyotrophy.

*Sugar Test in Diagnosis of Meningitis. J. Pignot.—p. 521.
*Influenza and Spirocheturia. Maclaud and Others.—p. 522.

Loose Joints.—Genevet presents evidence to prove that total resection of the elbow joint with proper treatment afterward will guarantee good functioning later. Even if a flail joint should result, this can be corrected by intervention at any time, as he describes, with illustrations of an old case. He advises total resection for all gunshot wounds of the elbow except when the bullet has merely traversed the joint, or the joint still contains projectiles; also for all grave suppurative lesions of the elbow in which ankylosis in a good position represents the best outcome to be otherwise anticipated. The statistics on record of resection of the elbow are very unfavorable, but investigation of the circumstances shows that the aftertreatment had been left to inexperienced hands in the unfavorable cases. In his nineteen cases of resection of the elbow, followed to date, most of them tardy interventions, all have healed with a neoarthrosis with good functioning in flexion and extension. In nearly every instance the excursions are complete, and they never have been less than 90 degrees, that is, a right angle. He relies on suspension with wire, fastening the stumps loosely together with wire. The joint is exercised at the earliest possible moment, as soon as the inflammation or pain has subsided. The ends of the wire loosely uniting the humerus and the ulna are twisted together for a certain number of turns, and then a rubber drain is slipped over the twist to isolate the wire from the tissues. Between the twenty-fifth and the thirtieth day he untwists the ends of the wire, cuts one end and pulls out the rest of the wire by the other end. No anesthetic is required. With the wire passed through the stumps they can be pulled up into a good position and held there, although there may be quite a gap between the stumps.

Sugar Content of Cerebrospinal Fluid.—Since Pignot first called attention to the diagnostic importance of the sugar content of the cerebrospinal fluid, experience has confirmed its value more and more. The sugar content shows no change from normal with meningeal symptoms, an aseptic and limpid fluid. The sugar disappears from the fluid with actual meningitis, and its progressive reappearance in acute nontuberculous meningitis is a sign of recovery. In case of a relapse, the sugar disappears anew, but returns as the critical phase passes over. The sugar content keeps normal also when serotoxic phenomena simulate a relapse. A reliable quantitative test for the sugar content is thus extremely important, and he says that this is realized by supplementing the Fehling test with a color test. The Fehling precipitate is treated with a 10 per cent. solution of ammonia molybdate. An intense blue tint develops proportional to the amount of the sugar present, even in the minutest quantities.

Spirocheturia in Influenza.—Maclaud reports the finding of spirochetes in the urine of thirty-eight among sixty-one soldiers with influenza.

*The Blood Groups. G. Giraud.—p. 21.
*Influenzal Purulent Pleurisy. L. Legendre.—p. 22.
*Lumbar Painful Point in Appendicitis. G. Bruu.—p. 23.

Classification of Blood for Transfusion.—Giraud summarizes the research of Moss in this line, and reaffirms the importance of selecting blood for transfusion which harmonizes with the recipient's blood, that is, in which agglutination does not occur. All that is necessary to avoid is the agglutination of the donor's red corpuscles by the patient's serum.

Influenzal Purulent Pleurisy.—Legendre says that 34 per cent. died of twenty-three men with purulent pleurisy in the course of influenza. Analysis of the fatal cases teaches the necessity for postponing the operation until the lungs have returned more or less to normal. The effusion can be tapped and cleared out by intrapleural injections of specific serum until the lungs are in a condition to stand an operation on the thorax. Before this, intervention invites disaster.

Lumbar Painful Point with Appendicitis.—Brun has had a number of cases of acute appendicitis in which the pains and contracture were more pronounced in the inferior lumbar region than in front. The appendicitis was retrocecal in these cases. This form is more common in children than in adults. The painful point in the lumbar region should be sought with care in conditions suggesting appendicitis, especially when there is not much to be noted in front. He has found this painful point in 30 per cent. of his cases. It is located above the middle portion of the right iliac crest. The maximum intensity is in the outer angle of the triangle of Petit. There may be contraction of the muscles of the posterior wall, and comparison with the left, sound side is instructive. These findings not only reveal appendicitis which might otherwise escape recognition, owing to the negative findings in the iliac fossa, but they also guide the surgeon to the most convenient mode of access to the appendix.

*War Neuropathology. E. Landau.—p. 33.
Duodenal Diverticulum in Man of 48. H. Siegrist.—p. 47.

War Neurology.—Landau reviews his experience during two and a half years' service in war hospitals in France to which neurologic cases were referred. He thus examined 8,000 neurologic cases, and among the points which impressed him was the instructive reflex to be elicited by tapping the side of the head of the radius. He calls the reflex thus induced the superior radiopronator. By testing for the Babinski sign fifteen or twenty men in succession, the variations in it with different pathologic conditions have convinced him that it is not a reflex in the ordinary sense of the term, but a phenomenon which no theory yet advanced will explain. With cases of neurosis, hysteria and psychoneuroses, he was very successful with his method of treatment which he calls psychic isolation. The first essential is that the physician must appear to the patient invariably exceptionally kind and sympathetic. But the examination is done in the presence of his friends and mates, and the findings are explained in scientific form but so all can understand. Textbooks may be passed around the circle—all to demonstrate that there are reasons for doubting the organic character of the affection. When possible, a patient with an actual organic affection of the kind is demonstrated at the same time, and the points of difference are emphasized. By this means, in two or three sittings, the man with merely a psychoneurosis becomes "psychically isolated" as his friends and mates feel that he is not a subject for sympathy and commiseration, and they thus become unconscious allies of the physician. Their criticism and ridicule soon bring the patient to a normal point of view, and he is cured. Paralysis, deafness, mutism, blindness, contractures and causalgia thus vanished in a few hours or days, like dew before the sun. Epidemics of hysteria befell the hospitals at times, and these were conquered in much the same way. A series of popular lectures was organized, the first on venereal diseases, the second on alcohol, and the third on psychoneuroses, emphasizing the differential points between actual mental upset after contusions and the phenomena of psychoneuroses. Men with the former are generally morose and silent, never noisy and turbulent. Actual cases were demonstrated, and then the lecturer, without dwelling too long on this, turned to another subject. In a few days noisy hysteria had disappeared from all the hospitals in Landau's jurisdiction.

*The Prevailing Febrile Pandemic. A. Lanfranchi.—p. 620.
*Epidemic Pruriginous Eruption. G. Sampietro.—p. 624.

Cleavage of Neutral Salts in Contact with Colloids.—Scala's research at the Istituto d'Igiene of the University of Rome has demonstrated that sodium chlorid and sodium sulphate and phosphate in contact with animal and vegetable colloids form compounds from which hydrochloric or sulphuric acid dissolve out in relatively large amounts. The first two thus entail an acid condition; the compounds with the phosphate entail an alkaline condition. In normal conditions, a balance is maintained, but otherwise acidity or alkalinity may come to predominate. The resulting disturbances form two great groups, one including pellagra, the other diabetes. He explains that improper diet or instability of the nervous system is the cause of the primary metabolic disturbance responsible for the upset.

Influenza.—Lanfranchi reviews the epidemics of influenza in recent decades in connection with epizootics in horses and other domestic animals.

Epidemic of Itching Eruption.—Sampietro compares reports from Spain with experiences in Italy showing the existence of a contagious itching eruption. Fal and Pineda encountered it at a few points in Andalusia and called it *prurigine epidemica microbica,* but in Italy it goes by the name of *rogna americana.* It affects the more sensitive areas of the covered skin, and is sometimes accompanied by fever, but the evolution is benign. A diplococcus is found in the depths of the papules. There is no evidence to incriminate an acaris.

*Influenza in Children. C. S. de los Terreros.—p. 641. To be continued.
*Ether by the Rectum for Children. A. Hinojar.—p. 657.

Influenza in Children.—De los Terreros was impressed with the small number of children affected with influenza in comparison with adults, and the lesser gravity of the disease in children. In all, the constant symptoms were supra-orbital neuralgia, the prostration during the acute phase and the depression during convalescence. In one child of 3 the very high fever subsided in three days and the child seemed recovering when it developed somnolency for two days. It could be shaken awake but dropped back into the stupor immediately—suggesting the so-called lethargic encephalitis. Epistaxis was common and seemed to be a favorable sign, never having been noted in the graver cases. He had one case in a 2 year old who had a convulsion and then extremely high fever but no other symptoms till death in scarcely more than twenty-four hours. The incubation period seemed to be about forty-eight hours. Among the sequels of influenza, the rapid development of pulmonary tuberculosis was the most serious. He has encountered quite a number of such cases among older children. A few children developed nephritis after the influenza; he ascribes this to injury from elimination of the disease toxins through the kidneys.

Ether-Oil Anesthesia by the Rectum.—Hinojar has now a record of 160 operations on the ear, nose or throat of children from 1 to 12 years old, under ether anesthesia by the rectum. This experience has convinced him that this procedure is absolutely harmless for children, while for adults serious by-effects are comparatively common. Children are certainly less susceptible than adults to the possible actions of ether, either from absorption or by reflex action from the intestines. If the ether is eliminated by the lungs too rapidly, respiration can be hindered and thus the action of the anesthetic prolonged, or a few whiffs of chloroform can be given in addition. There is no phase of excitement with ether given by the rectum, but there may be a tendency to vomit and hence the stomach should be empty when the child comes to the table. Vomiting with the ether alone does not occur till tardily, usually the next day. He gave 50 gm. each of ether and oil to children under 3; above this age he increased the proportion of ether, 65 to 55 of oil, for children from 3 to 5; 80 to 65 of oil from 5 to 8, and, from 8 to 12, 90 gm. of ether to 75 gm. of oil, but he did not hesitate to increase these doses at need as experience confirmed the tolerance of the children. With adults, on the other hand, he had three fatalities; these patients all had cancer of the larynx or tongue and one had chronic colitis besides.

*Inherited Malaria. E. Tejera T.—p. 244.
Oxytocic Action of Quinin. J. de D. V. Ruiz.—p. 245.
Influenza. J. R. Carcaño.—p. 246.

Inherited Malaria.—Tejera examined under the microscope the blood of newly born infants in his district, where malaria is endemic. The blood from a finger, drawn a few minutes after birth, revealed the *Plasmodium vivax* in one child and the *falciparum* in another. In these two cases the women had been under treatment for florid malaria for a short time before delivery. No quinin was given in one case as the family feared it might bring on a miscarriage. In the other an abortion at the fourth month was under way. The falciparum was cultivated from the blood and also from the spleen and liver of the fetus. In the first case the blood in the child was examined at the twelfth, twenty-fourth, seventy-second and ninety-fifth hours, with positive findings each time. At the forty-eighth and ninety-fifth hours the child's temperature had run up to 39 C. paralleling a febrile paroxysm in the mother. Two further parallel febrile attacks were seen in the child and the mother, but then quinin treatment was begun and pushed and the clinical picture was soon modified. Tejera cites some recent writers to the effect that only three authentic cases of inherited malaria are on record.

Medicina Ibera, Madrid

Nov. 23, 1918, **5**, No. 55

*Some Contraindications for Heliotherapy. A. Sierra.—p. 183.
*Treatment of Influenza. A. S. Alvarez.—p. 183.
Atypical Chancres. Sicilia.—p. 185.

Nov. 30, 1918, **5**, No. 56

*Influenza. R. Velasco.—p. 209.
*Metastatic Gonorrheal Conjunctivitis. B. Carreras.—p. 210.
Influenzal Bronchopneumonia. A. Piga.—p. 214. Com'd in No. 55, p. 186.

Contraindications for Heliotherapy.—Sierra states that while in the majority of cases of surgical tuberculosis marked benefit is realized from partial or total sunbaths, in certain cases the lesions seem to be whipped up to greater activity. This latter group includes the febrile cases. Extreme caution is indispensable when there is fever of even tenths of a Centigrade degree. If the temperature is half a degree or more above normal, sunbaths will aggravate the condition, and hence heliotherapy is contraindicated in these circumstances. Bone or joint tuberculosis is benefited more by sunbaths than pulmonary tuberculosis. Another contraindication is a tendency to hemophilia and hemoptysis. The sunbaths are liable to bring on hemorrhages difficult to control. Heart disease and valvular lesions, no matter how perfect the compensation, likewise contraindicate heliotherapy. Precordial anguish, palpitations and syncope are liable to be brought on by somewhat prolonged sunbaths. Sierra urges to exclude from heliotherapy nervous patients; congestions and general excitement are liable to follow heliotherapy. He warns further that albuminuria likewise contraindicates it, as the edema may spread and fatal uremia may develop; hence the necessity for analysis of the urine before applying heliotherapy. In conclusion he warns against sunbath treatment for the much debilitated, especially children, for those exhausted by long suppuration, and cachexia. He gives only these general principles without citing any specific instances.

Iodin Treatment of Influenza.—Alvarez gives iodin internally and sodium sulphate in enemas, and extols the efficacy of this combination in treatment of influenza. He gives 5 drops of tincture of iodin every three hours, from the beginning of the disease. He says it has a bactericidal action, neutralizing, tonic, antitoxic and immunizing action, regulating the temperature, cell functioning and circulation, while reducing congestions. The best vehicle for it seems to be milk alone or coffee. Scientific theory and clinical experience confirm the benefit of this treatment. In prevention, he orders as the minimum dose for an adult 15 drops every eight hours. He cites other writers who laud the use of iodin internally, and he does not hesitate to call it a fundamental treatment for all infections. (The tincture of iodin of the Spanish Pharmacopeia is of 10 per cent. strength.)

Influenza.—Velasco in this second article emphasizes the marked tendency to hemorrhage in some of his cases of influenza. One robust young priest had a hemorrhage from the lungs of about 350 gm. of pure blood the fourth day and died eighteen hours later. He was impressed further with the absence of high temperatures even in the gravest cases.

Metastatic Gonorrheal Conjunctivitis.—Carreras remarks that metastatic conjunctivitis may be a manifestation of gonorrhea which has apparently subsided completely. In one case of gonorrhea, one knee developed arthritis and one eye showed a metastatic affection of the conjunctiva and cornea with iridocyclitis — an actual segmentitis, but complete recovery followed. From one to four weeks is the usual duration of metastatic gonorrheal conjunctivitis. In Carreras' case recovery was complete within thirteen days, but the joint lesions long persisted. In addition to the usual simple measures for treatment of the eyes, vaccine therapy was applied. The cornea in these metastatic cases is rarely affected; he knows of only one case with rapid and complete destruction of the cornea. But iridociliary lesions frequently complicate metastatic conjunctivitis.

Volvulus of Left Colonic Angle.—Blanc Fortacin's patient was a woman of 40, previously healthy, and the ileus from volvulus of the sigmoid flexure had lasted for four days. Exudation in the peritoneal cavity testified to some infection yet the intestines showed no signs of paralysis outside of the twisted loop, and the general condition was surprisingly good. There was evidently edema in the twisted loop preventing passage of flatus even after the volvulus was reduced. Consequently there was danger of damage with strong peristalsis waves, and to avert this he punctured the cecum to permit escape of gases. By the thirty-sixth hour the normal course of the intestinal contents had been resumed, and recovery was complete at once.

Bone Grafts. J. B. Abalos.—p. 499.

Amputation of Foot.—Baraldi gives an illustrated description of what he calls the operation of P. Duval. It is the last link in the chain of osteoplastic operations that can be done between the calcaneum and the tibia; it is intermediate between the Pirogoff and the Guyon amputations. No matter how much the foot is crushed, this technic is almost invariably applicable and it leaves the patient with a useful leg. The ventral position is peculiarly advantageous for all plastic operations on foot and leg. The elliptical incision passes from the interline of the tibio-astragalus articulation down to the farthest rear of the sole, 15 or 20 mm. in front of the vertex of the arc formed by the profile of the heel. The posterior aspect of the calcaneum is sawed off perpendicularly, forming a plate about 1 cm. thick, and then the foot is amputated just above the malleoli. The flap cut from the calcaneum is sutured to the stump of the tibia with catgut or with a wire passed around the flap and through the tibia. The wire had to be removed later in one case, and he intends in future to use kangaroo or reindeer tendon as taking longer to be absorbed than catgut. In the case described the foot had been run over by a car wheel but the stump can be used now, a year later, exactly like a normal sole. The man is now fitted with an artificial foot.

Physiopathic Nervous Disturbances.—Fracassi reports a case which he thinks is the first of the kind to be described in Argentina. It resembles in every respect the nervous disturbances after war wounds which Babinski calls reflex nervous disturbances, or physiopathic syndromes. There was no wound, but the man of 34 had been repeatedly severely chilled in working in the fields in the rain, and he developed tetany, with painful spasmodic contracture of the hands and feet exactly like the accoucheur's hand contracture noted after war wounds. It has been ascribed to immobilization, but there had been no immobilization in this case. The microsphygmia, loose joints and other symptoms of Babinski's physiopathic syndrome were all present; the limbs were weak and there was both hypotony and atrophy in certain muscles of arms and legs. In another case the traumatic clubfoot was the result of chronic arsenical poisoning; in others of leprosy, or of extreme fatigue—some of these factors have evidently cooperated in the development of physiopathic disturbances after war wounds. The constant coexistence of hysteria with the physiopathic disturbances sustains the close connection between them, and explains them as the result of blocking of the sympathetic nervous system. This blocking might be overcome by some intense, painful electric stimulation capable of generating powerful counter inhibition, as Tinel has advocated.

Cancer of Uterus.—Abalos has been visiting in Europe and here relates some of his impressions as he journeyed from one surgical service to another. He was impressed with the earlier stage of uterine cancer which European surgeons see in comparison to what occurs in Argentina. Surgeons outside of the great surgical centers are too apt to wait for the diagnosis of cancer to be certain—by the time the malignant nature of the affection is beyond question, the growth is too often inoperable. He cites Pollosson's dictum that operative treatment is required in every case of uterine cancer unless there are formal contraindications. The latter now has a record of over 400 Wertheim operations with 35, 61 and 69 per cent. permanently cured, for three or four years or longer. He emphasizes that the fundamental condition for extensive abdominal operations is the dissecting out of the ureters through their entire course in the pelvis. In his latest series, the actual cures, according to Winter, were 52 per cent.

Thrombosis of Lateral Sinus.—Rizzi reports a case which deceptively simulated tuberculous meningitis, in a girl of 11 with a tuberculous mother. When he saw the child first, the thirteenth day, the main symptoms were somnolency although the mind was clear, irregular fever, the back of the neck rigid, the pulse fast, not modified by change of attitude, pain in the mastoid region and over the squamous bone, but no convulsions, no strabismus or anisocoria. His diagnosis of thrombosis of the lateral sinus was confirmed by the operation, not permitted till the fifteenth day, when the child was already in coma. No benefit was realized apparently from the extensive operation, and the child was apparently moribund, when, the fourth day after the operation, he succeeded in discovering a large decomposing parietal thrombus. Removal of this transformed the clinical picture at once, with rapid recovery. Such cases teach the folly of attempting to cure without amply opening up the sinus and carrying the investigation far beyond the apparent confines of the lesion.

Syphilis of the Uterine Adnexa.—Castaño does not hesitate to assert that syphilis is always involved in fibromatous lesions of the uterine adnexa. He has never encountered a fibroma of the kind except in syphilitics, the disease inherited or acquired. The tendency to sclerosis, especially when there are preexisting or concomitant gonorrheal or streptococcus lesions, results in those tubo-ovarian abscesses or bilateral salpingitis which fuse the adnexa into a solid, knobby mass sometimes involving the uterus or bowel or both. This conglomerate can be recognized by palpation. Although it seems to be an extensive inflammatory process, only amenable to a radical operation, yet under combined mercurial and iodid treatment the whole process is liable to retrogress completely, and the patients live the rest of their lives in perfect condition so far as these organs are concerned, free from pain and hemorrhages. Attempts to operate in this class of cases have resulted in the highest mortality of all gynecologic interventions.

In his service he gives systematic treatment for syphilis as an indispensable preliminary to operation in all cases of fibromas. This smoothes the way for the operation in every case and often renders it unnecessary. Very few cases of syphilitic adnexitis have been published, as every one takes it for granted that the whole process is referable to the gonococcus or streptococcus, thus failing to recognize the share of syphilis in the lesion. Examination of the tubes after removal will often show that the lesions are of a gummatous type. In every case the syphilis tends to induce sclerosis and adhesions. This should be borne in mind at all operations in this region as the sclerosis and the adhesions may retrogress under specific treatment and there is no need to break up the adhesions to other organs. Vessels and lymphatics may have developed in them to such an extent that it is dangerous to cut or tear them. In the differential diagnosis it is important to remember that with a fibroma in the uterus its cavity always enlarges. If a catheter shows that the uterus cavity is only 6 or 7 cm. long, the assumption of a fibroma can usually be discarded.

The Psychophysiology of Aviation.—Lopez reviews some of the points that have impressed him in his observation at the military aviation school. He says that every muscle in the body is worked in the process of flying, that is, during equilibration in the air. The muscular movements are gentle, but all the muscles are involved sooner or later in the flight.

Tapeworm in Cat.—Parodi found in a cat nine specimens of the *Dipylidium trinchesci*. It is the first time that this parasite has been recognized at Buenos Aires. Its intermediate host is not known.

Disinsertion of Mesentery with Strangulated Hernia.—Gallo reviews cases of this kind on record and reports a case personally observed. His patient was a married woman of 54. The mesentery of the strangulated loop in the femoral hernia had been torn loose, and it was sutured after 50 cm. of the loop had been resected.

Ferment in Ovarian Extract That Coagulates Milk.—Goldemberg describes experiments which demonstrated in ovarian extract a proferment that, when activated with calcium chlorid, coagulates milk.

Tuberculosis in Spaniards in Argentina.—Coni has brought down to date his statistics in regard to the racial prevalence of tuberculosis. The figures show a death rate from tuberculosis per ten thousand inhabitants of 28.6 for the Uruguayans in Buenos Aires, while the figures are 17 for the Spaniards, 16 for the Argentines, 10.7 for the Italians and 8 for the Russians.

Perforation of the Stomach After Echinococcus Disease of Liver.—In Bambaren's case the young woman had been operated on twice for echinococcus cysts in the liver. In dressing the wound after the second operation, stomach contents were found in the cyst which had been sutured to the lips of the laparotomy incision. With enteroclysis and Fowler's position, heart tonics and ice to the abdomen, the condition improved and the opening into the stomach seemed to heal spontaneously. There must have been localized peritonitic adhesions enough to wall in the process and prevent serious complications from the perforation. If the operation had been delayed a few days, the cyst might have perforated into the stomach, and its contents passed out this way.

Chemical Research on the Gastric Juice.—Landolph has been analyzing the gastric juice of dogs, and describes the technic with which the chlorin in the three fractions of the distillation can be determined.

Prophylaxis of Syphilis.—Raíces advocates, besides the usual general prophylactic measures, absolute suppression of attempts to regulate prostitution; arrangements for medical treatment of venereal diseases in connection with all state establishments with a considerable number of employees, and intensification of all means for diagnosis and treatment as outpatients or in hospitals. His tabulated statistics show that in the last five years the number of new cases of syphilis ranged from twenty to 100 each month, only two months showing a lower figure than this—seventeen and twelve. He emphasizes that if girls are not enlightened by their mothers, the day comes when Nature enlightens them, and the natural instincts speak louder than the conventions. Nature pushes and does not warn of any dangers.

Fundamental Considerations in Roentgen Therapy. B. N. Canovas. —p. 973.

Anesthesia in Hysteria.—Herrero comments on the well established fact that persons in extreme excitement, profound emotion, may not feel pain from some serious wound. The consciousness does not register the sensation of pain. There is evidently some congestion in the endocosmos which shuts off the innervation of the organic periphery, even in the healthy. This absence of perception (mental vision) is a feature of hypnosis. This action and reaction between the psychic endocosmos, the innervation and the peripheral organism from the Ariadne's thread which leads us out of the maze of hysteria.

Psychiatry and the War.—Rivers remarks that the influence of the war on psychiatry has been enormous. The most important effect has been the closer relations between psychiatry and neurology. Another change has been the greater respect paid to psychanalysis by many who before were hostile to it. The Freud school of psychanalysis have learned that sex is not the sole factor in the production of psychoneuroses but that other instincts, self-preservation, etc., may also intervene in the production of psychoneuroses.

*Contagious Jaundice with Spirochetes and Symptoms Suggesting Blackwater Fever. W. Schüffner.—p. 1.
*Blackwater Fever. C. D. de Langen.—p. 26.
*Gallstones in the East Indies. C. D. de Langen.—p. 44.

Spirochetes in Blackwater Fever.—Schüffner reports the discovery of spirochetes numerous in the blood of a robust young native of Java who died within two days with symptoms of acute blackwater fever. His photographic reproductions of the microscopic findings show the spirochete without coils. Inoculation of guinea-pigs with the patient's blood was constantly negative, although it was swarming with the parasites. It is possible that young guinea-pigs might prove more susceptible, and he urges that they should be given a trial in such cases as also all other laboratory animals and the larger domestic animals. Perhaps by so doing an intermediate host may be discovered. In two other cases the disproportion between the serious general condition, suggesting severe poisoning, and the objective findings was striking; inoculation of guinea-pigs was also negative and no spirochetes were found in the blood but possibly this was due to inefficient technic. In the case mentioned first, various modifications of the technic had to be tentatively tried before the spirochetes finally showed up. In cases of blackwater fever in future, the blood should be examined at the earliest possible moment and the eyeballs should be examined for evidences of jaundice. The high leukocytosis, pains in the calf and the serious general condition will aid in differentiation.

Blackwater Fever.—De Langen reports his study of nine cases of blackwater fever, including two in Europeans. The resisting power of the red corpuscles seemed to be normal, but the residual nitrogen was exceptionally high even in the cases without anuria. He is convinced that the share of quinin in the origin of blackwater fever has been much overrated. He was never able to find anything resembling the cell enclosures described by Leishman. In treatment, heart tonics and calcium salts were the main reliance and eight of the patients recovered. Quinin was not given except to one patient with tertian malaria. Cholesterol given in the form of egg yolk did not display any benefit. In the last case, intramuscular injection of 15 c.c. of blood serum from a normal person was followed by a drop in the temperature. In two days the defervescence was complete while the hemoglobin disappeared from the urine, and except for the severe anemia the patient seemed perfectly normal. Two months later the patient developed the same set of symptoms anew. Immediately he was injected with serum—this time fresh dysentery serum was used as it happened to be on hand —and the next day the urine was normal once more. These two experiences justify further attempts in this line.

Gallstones in the East Indies.—De Langen states that only from 3 to 11.2 per cent. cholesterol was found in gallstones found in fifteen cadavers. In only one of the cases had the cholelithiasis been suspected during life. There have been only thirty cases of gallstones diagnosed in the last ten years in the government infirmaries among the 422,943 admittances. These figures confirm his previous statements, mentioned recently in these columns, as to the rarity of gallstones in the East Indies, and the exceptionally low cholesterol content of the blood in the natives.

Suprarenal Extracts of Different Origins.—Van Leeuwen's tests showed absolute concordance in the action of several makes of suprarenal preparations, only one, and this a domestic product, differing in its action.

The Agglutinating Test with Proteus Cultures in Typhus. —Bijlsma says that the extensive literature on the Weil-Felix test agglutination in diagnosis of typhus has demonstrated its practical usefulness, although a scientific theoretical explanation is still lacking. The proteus strain in question, the X strain, as they call it, was cultivated from the urine of two patients with typhus. By repeated cultivation of the proteus from typhus urine they finally found one strain, X 19, which is agglutinated by typhus patients' serum even extremely diluted. This strain is the one now commonly used for the tests. Others have cultivated similar strains from both blood and urine; the technic for the test is the same as for any agglutination method. Preparations made with this strain for indefinite conservation, like Ficker's "diagnosticum," are said to have given good results by certain German investigators. The proteus test seems to be specific for typhus. In other diseases the response is negative or it occurs only with high concentration.

Early Microscopic Findings in Lupus of Nasal Mucosa. K. A. Heiberg and O. Strandberg.—p. 1585.
*Intussusception of Stomach. J. Fabricius-Møller.—p. 1592.

Intussusception of the Stomach.—Møller gives an illustrated description of the findings at necropsy of a woman of 66 with acute stenosis of the pylorus from intussusception of the stomach into the pyloric region and incarceration in the duodenum of a large pedunculated papilloma in the stomach. The neoplasm had probably existed for many years but had caused no symptoms until not long before death. He has been able to find only two analogous cases in the literature, one of them Wade's case. All the patients were elderly women with a pedunculated tumor which had not caused symptoms until it slipped into the duodenum. Signs of stenosis of the pylorus are the first to attract attention, either chronic or acute as in Møller's case. Blood in the stools and jaundice may be observed, but the prognosis depends on the promptness of operative relief. In conclusion he refers to Ederlen's case in which the invagination occurred in the much dilated esophagus.

*The Abdominal Reflexes. G. H. Monrad-Krohn. Supplement, pp. 1 to 180.

Trauma of the Brain.—Harbitz discusses from the medicolegal standpoint traumatic apoplexy, traumatic neuroses and traumatic pachymeningitis, reporting some typical instances of each with his conclusions as to treatment and the causal connection with the trauma. In some of the cases there was an interval of several months between the accident and the apoplexy, and necropsy revealed old arteriosclerosis or old foci of softening of the brain manifestly antedating the accident. Such a combination imposes scepticism and criticism. Some of the cases illustrate the consequences of trauma in an already pathologic brain, as for example in a case of death a month after a fall on the back of the head. Necropsy showed accumulation of blood between the meninges, but there was evidence of old pachymeningitis. The latter entailed the hemorrhages which proved fatal, but there would probably not have been any hemorrhages from the previously latent pachymeningitis if it had not been for the fall. His seven patients were all elderly except one robust man of 38 who developed rapidly fatal tuberculosis after he had been confined to bed from the consequences of a contusion of the brain. The direct importance of the trauma in this case was unmistakable. His cases demonstrated further that an actual traumatic injury of the brain can be accompanied or followed by a secondary neurasthenia or hysteria.

Temperature Changes in General Paralysis.—Lie is chief of the Dikemark Asylum and he relates that there were thirty-eight deaths from general paralysis there in the last three years, but none from gangrene. In four cases the temperature charts of the last month before death recorded extremely low temperatures. In one case it declined to 26 C. in five days; in another case from 35.5 to 22 C. in twenty-four hours. In another case the decline was more gradual, dropping to 25 in the course of eight days. The temperature was taken in the rectum each time. One of the above thus breaks the record for low temperature in general paralysis, with his 22 C.

Purpura.—The first part of C. Johannessen's article was reviewed in this department, page 318. He here discusses the hemorrhagic purpuras of the idiopathic type with essential thrombopeny, pseudohemophilia. A typical case is described which illustrates the wide divergence of the clinical picture from that with anaphylactoid purpura, analyzed in the preceding instalment: the temperature persistently normal, never any joint or colic pains, and the blood showing lymphocytosis and leukopeny, with from 2,000 to 4,000 blood platelets. The chronic Werlhof's disease in this case was intermittent, but in a second case described the disease was continuous, although milder. The acute form develops like the chronic form but generally terminates fatally in from two to four weeks. He reports a case in a male infant, 2 years old, in which the mother noticed a purpuric patch on the right thigh and left leg; the child seemed normal otherwise. The patches increased in size and number and the next day the child vomited once and there was some blood in the vomit. The child died the third day. Besides these chronic and acute forms of typical Werlhof disease, other diseases may present symptoms resembling those of Werlhof's disease, but examination of the blood may reveal lymphatic leukemia as in a case described in a young child. A toxic symptomatic form has also been observed with chronic poisoning, especially benzol poisoning.

The prognosis is grave for the acute forms but in the chronic cases it depends on the treatment. Oversight of the condition is best realized by frequently repeated count of the blood platelets. The assumption of a myelogenous origin, which he accepts, calls for arsenic treatment. This is said to rouse the bone marrow from its torpor and stimulate production of platelets, but he never witnessed any appreciable benefit under arsenic. Splenectomy has given promising results but it is still in a tentative phase, and the ultimate outcome is unknown as yet. Gelatin by mouth and subcutaneously should be given a trial, to ward off or arrest hemorrhage. Von Velden advocates repeated injection by the vein of 5 or 10 c.c. of a 10 per cent. solution of sodium chlorid. To increase the number of blood platelets is the main thing, and the first and foremost measure for this is direct transfusion of blood. His first case testifies most strikingly to the benefit possible with this; it serves another purpose also in restoring the blood lost in the hemorrhages. Fonio has demonstrated the feasibility of centrifuging out the blood platelets and injecting them alone or an extract of platelets. With hemophilia there is also insufficiency of blood platelets. It usually begins about the age of 2, and at 7 or 8 the joints may show the typical hemophilic lesions, which so often get labeled tuberculosis or syphilis. A history of a hemophilic tendency may be the only clue. In treatment, rest, compression and cold packs, with cautious use of the joints after a few days. Cautious massage promotes absorption. Absolute disuse favors contracture; too forcible measures are liable to cause bleeding in the joints. General strengthening and symptomatic measures are indicated, the same as with Werlhof's disease, with extract of blood platelets in particular.

Examination of the Heart.—Salberg in dubious cases has the patient recline for a few minutes and then stand up. The heart sounds become much more instructive when examined in this way.

Sarcoma of Iris.—Berner states that the sarcoma removed from the lower part of the left iris seemed to resemble those in Wood's and Pusey's cases. There has been no sign of recurrence in the case reported during the two years to date, and vision is 5/10 without glasses.

Abdominal Reflexes.—Monrad-Krohn's monograph is based on examination of 472 cases at various hospitals for nervous and children's diseases at London and Christiania. He gives eleven pages of bibliographic references (titles in full), with a five page summary in English. Among the facts he has ascertained are the increased intensity of the abdominal reflex in paralysis agitans and in chorea, and the attenuation in hysteric hemihypo-esthesia. The normal abdominal reflex is homosegmental, and it may be epigastric, or above, including, or below the umbilicus. There is also the periosteal deep reflex of the costal margin. The abdominal reflexes are so constant in health and give such important information in pathologic conditions, as he describes in detail, that testing this reflex must be regarded as an important link in the chain of routine general and neurologic examination. A heterosegmental abdominal reflex points to partial paralysis of the abdominal musculature without pronounced sensory deficit phenomena. He theorizes that the reflex arc reaches up to the brain, and that it is under the control to a certain extent of that part of the nervous system which is damaged in paralysis agitans and chorea.

THE OCCURRENCE OF SUPERFETATION *

ARTHUR WILLIAM MEYER, M.D.
PALO ALTO, CALIF.

From time to time reports of alleged instances of human superfetation appear in current medical literature. Reports of similar instances in other mammals occur also, although more rarely, in the nonmedical literature. As recent instances of the former may be cited the cases reported by Logan[1] and Gustetter.[2] Of instances of the latter may be mentioned the cases of King,[3] Sumner[4] and Harman.[5] The latter group of cases were found in the rat, the mouse, the cat and the cow, respectively.

Without accepting the alleged cases in mammals with bicornate uteri as unequivocal, it is easy to see that aside from ectopic implantations, the conditions under which superfetation necessarily would have to occur in the human uterus may be totally different from those that may obtain in bicornate uteri. Since the usual intermenstrual period in women is twenty-eight days, it would also seem, as often asserted, that the older of two fetuses in a case of human superfetation certainly would occlude the uterine cavity rather effectively, and alone make fertilization of any ovum, liberated at a subsequent ovulation, difficult. It would seem to do this entirely aside from the possible effect of the cervical mucous plug so frequently referred to.

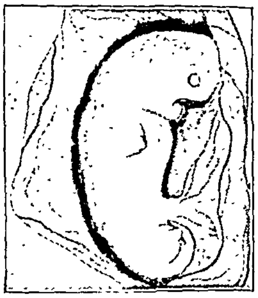

Fig. 1.—Superfetus from the cat, after Harman.

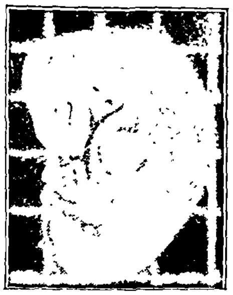

Fig. 2.—Normal cat fetus, approximately 10 mm. long when fresh.

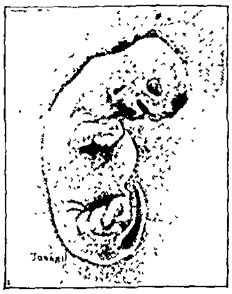

Fig. 3.—Macerated, distorted, normal cat fetus, after Kunz.

These things are true especially in such instances as that of Gustetter's, in which the time interval between the ages of two fetuses is estimated to have been as great as sixty-five days. Moreover, it would seem that the development of the first fetus and that of the corpus luteum in such a case as this would have inhibited the occurrence of subsequent ovulations. An obstacle to the implantation might also be found in the condition of the decidua, even if later ovulation actually occurred. Since Loeb[6] found that in the pregnant guinea-pig the endometrium cannot be stimulated to form a new decidua, it is evident that the fertilized ovum might encounter insuperable difficulties if similar conditions obtained in the human being. However, if a young blastocyst really can become implanted on the bare surface of an ovary, or on the peritoneum, even, then it may well be doubted whether a new decidual reaction is essential for implantation of the ovum in the human being. Furthermore, when implantation in the graafian follicle occurs, there probably is no decidual reaction, at least nothing comparable to what occurs in the uterus, although I presume that a corpus luteum might possibly act vicariously to some extent. However, there are other obstacles, such as those mentioned above, and the possible occlusion of the uterine tubal orifices in consequence of hyperplasia of the musculature.

Although it is being established that ovulation and menstruation apparently are not contemporaneous phenomena, succeeding ovulations nevertheless probably are periodic and separated by a considerable interval of time from each other. Such a conclusion seems to be fully warranted, although it is, of course, well known that ovulation may occur without menstruation in normal nonpregnant women. This, however, does not establish that ovulation occurs during pregnancy also. According to Fraenkel[7] and Miller,[8] ovulation normally precedes menstruation by about nine days. Cosentino,[9] and also a few others, have reported cases of ovulation during pregnancy in women, but we unfortunately know little as to the exact conditions which obtained, so that the entire matter remains as yet rather undecided.

Franco,[10] while reporting a case of spurious superfetation, gave a long list of Italian writers who were

said to believe in the occurrence of superfetation. Unfortunately, this literature at present is largely inaccessible to me in the original, and such as is accessible remains unconvincing as all of it apparently was to Cuzzi, who is reported by Franco as regarding superfetation only as a theoretical possibility. Nor does there seem to be good evidence that ovulation occurs during pregnancy in other higher mammals. The only case cited is the questionable one in a cat reported by Christopher.[11] At present it has not even been established that superfetation occurs in the rare cases of double ovarian, or of combined ovarian and uterine pregnancies, although these cases furnish far more favorable conditions. Did the alleged occurrence of superfetation not involve a series of assumptions, each one of which remains unproved, belief in it would seem easier. Consequently, in view of all these things, it would seem that the concluson of Gustetter that superfetation is "a frequent though often overlooked cause" of abortion in women is rather venturesome.

The possibility of superfecundation, however, is not necessarily excluded by these considerations, for ova from the same ovulation still might be fertilized at somewhat different periods by some spermatozoa from the same or from subsequent coituses. But even while theoretically possible, it is evident that the relatively limited period of vitality of the unfertilized ovum, as contrasted with the duration of pregnancy, would make it extremely difficult, if not impossible, to recognize such cases. This would be true even if they occurred in the earlier stages of development, for normal growth differences are too great when contrasted with the greatest differences that could possibly exist under these circumstances. This would seem to be true even if we grant that the spermatozoa have a somewhat more tenacious life than ova. In all instances in which the discrepancy of size or development between two fetuses is such as to suggest that one of them arose from an ovulation so far removed from the other as to produce unusual differences in size in the later months of prenatal development, the assumption of independent action of the ovaries, considered by King in the case of the rat, would not avoid the foregoing difficulties. Nor could the occurrence of deferred fertilization, which is advanced by Sumner as an explanation for the occurrence of supernumerary broods in mice, be used as an explanation in human cases, for the period of vitality of both the ovum and the spermatozoon would seem to be entirely too short to become responsible for marked developmental differences.

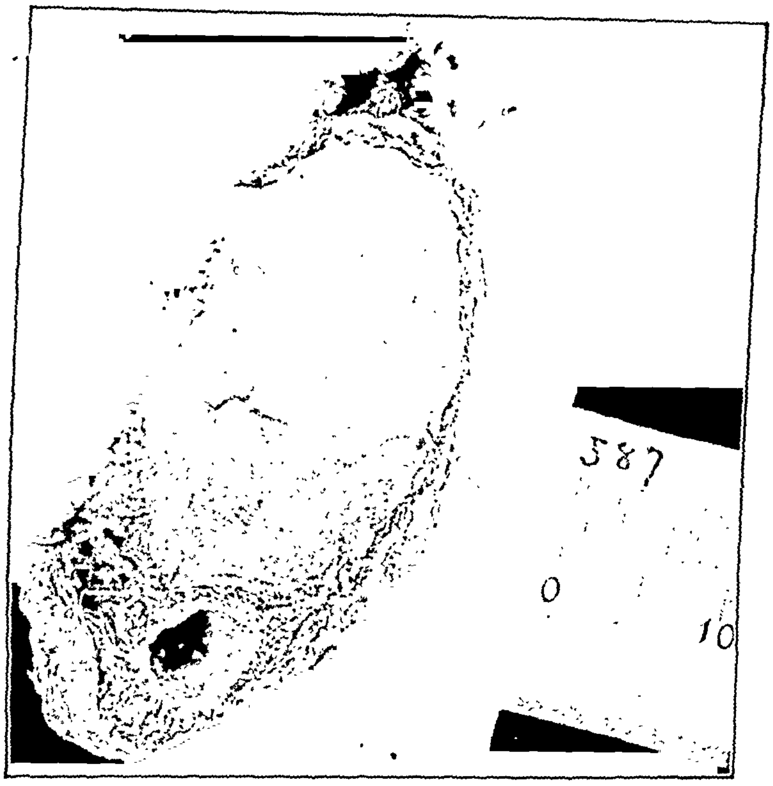

Fig. 4.—A case of pseudosuperfetation, No. 587, from the Mall Embryological Collection; × 2. All fetuses shown in Figures 4 to 12 are twin, as indicated by the numbering.

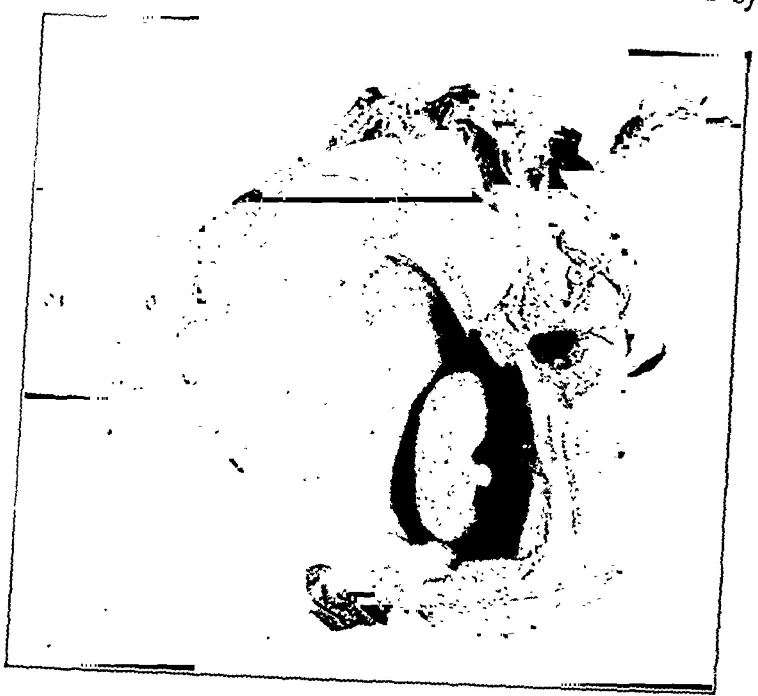

Fig. 5.—Pseudosuperfetus 788 *a* from the Mall Embryological Collection; × 1.

Sumner found supernumerary litters to occur in 3 per cent. of 250 broods in young mice. Such litters were particularly frequent in young deer mice. The frequency of supernumerary broods would seem to vary greatly in closely allied mammals, however, for King observed only two cases, and these she regarded only as "seemingly" instances of superfetation among 700 normal broods in rats. This is an incidence of only 0.28, or a frequency only one-eleventh as great as that found by Sumner in mice. Sumner also stated that more than 80 per cent. of the supernumerary broods survived nearly or quite nearly to maturity, and King added that all of those broods in rats were raised to maturity and that some were used for breeding purposes later.

Although both King and Sumner regarded the occurrence of superfetation with considerable reserve, neither seems to have considered the possibility of delayed parturition in one horn of the uterus as worthy of consideration in connection with supernumerary broods between which the time interval was short. Whenever this interval was relatively long as contrasted with the gestation period, such a suggestion is untenable, to be sure, unless corresponding developmental differences were present. It might be helpful as well as interesting to have a careful gross and microscopic examination of the broods concerned in order to contrast the respective states of development.

[11] Christopher, W. S.: Ovulation During Pregnancy, Am. J. Obst. **19,** 1886.

Since Fraenkel[7] found that some rabbits copulate while pregnant, it would be of especial interest to know if supernumerary broods are particularly common in such rabbits and whether supernumerary broods can be produced in mice should comparable conditions obtain. A particularly interesting question would seem to be raised by the occurrence of such cases as reported by Guerra[12] in which a second *implantation* is said to have occurred while a dead fetus still was retained in utero. Under these circumstances the smaller, younger fetus should always be best preserved. Although ovulation and perhaps also menstruation could occur under such circumstances in view of the well known regeneration of the endometrium, possible under these circumstances, one scarcely can regard such a sequence of events as established, at present. However, Franco[10] stated that *there is no lack of cases in which a second pregnancy* occurred under such circumstances.

Sumner quite rightly called attention to the fact that in the great majority of cases of superfetation recorded in man, one or both fetuses were macerated before born, and King concluded that "many cases that have been reported as due to superfetation unquestionably are instances of superfecundation or of blighted ova." Nevertheless, King regarded the case in a sheep reported by Arrowsmith[13] as probably genuine, and added that "although Christopher found that ovulation might occur during pregnancy in the cat, superfetation is not known to occur in this animal." However, Jepson, in 1883, reported such a case, and Harman[5] another. Neither report, however, would seem to bear critical scrutiny, although both are quite as trustworthy as other reports of alleged superfetation. In the case of Harman it would seem more probable that intra-uterine death of one fetus with survival of the other was responsible for the interpretation. It should be recalled that such instances are relatively common in the rat, guinea-pig, rabbit, ferret, marmot, the pig, and in some other mammals. These phenomena have been discussed by Strahl and Henneberg,[14] Henneberg, in 1903, Fraenkel,[15] Koebner,[16] Huber, [17] Mall[18] and Meyer.[19]

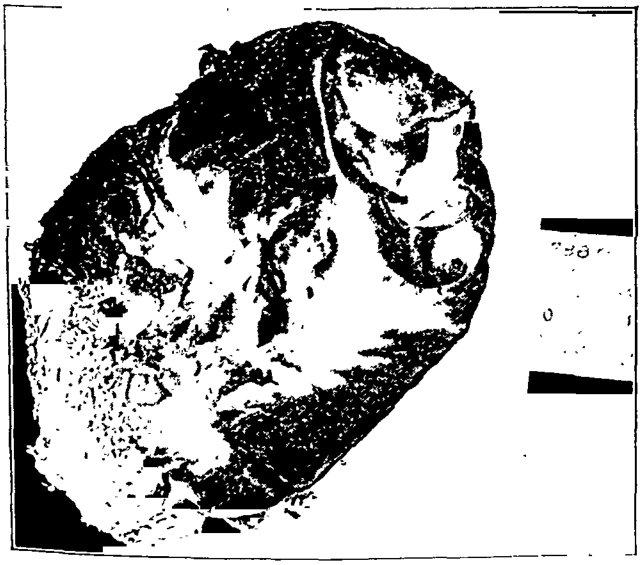

Fig. 6.—Pseudosuperfetus 788 *b* from the Mall Embryological Collection; the small nodule in the shaded area opposite the scale is the fetus; × 1.

As is evident from Figure 1, in which the so-called younger superfetus, reported by Harman in a cat, is contrasted with the normal cat fetus (Fig. 2) of approximately the same length, the latter has a totally different form. The same thing is evident also, although to a lesser degree, on comparing the illustration accompanying Harman's article with one from Kunz,[20] shown in Figure 3. Since the latter, the larger of two macerated apparent superfetuses, in the report of Kunz, was deformed by retention, it may have measured a little more or less—probably more—than 10 mm. at the time of its death. However, even were it a trifle older than the fetus in Figure 2, as its form would seem to suggest, the difference is slight and may be ignored for purposes of comparison. Kunz spoke of the larger fetus shown in Figure 3 as entirely normal, which it apparently was, for the deviations from the normal form (Fig. 2), which the illustration so clearly shows, undoubtedly are due to postmortem, antepartum changes so common in human abortuses. Kunz's conclusion that all three fetuses in his case in the cat resulted from ova which were fertilized approximately at the same time heartily commends itself. Kunz further concluded that these specimens furnish no evidence for the occurrence of superfetation, in spite of the fact that two smaller macerated distorted fetuses, which were *only* 9 and 10 mm. long, accompanied a nearly full-term fetus.

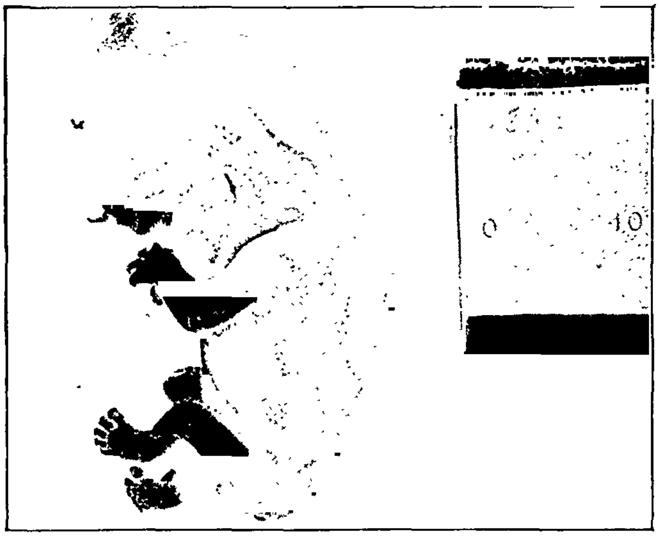

Fig. 7.—Similar specimen, No. 1840 *a*; × 1.7; only slight maceration is present.

Harman[5] also reported a case in the cow which, however, she regarded merely as one of "probable superfetation." Unfortunately this report rests very largely on the statement of a veterinarian, who made no further examination of the specimen. Hence it
